## Preface

The guiding principle in this book is to use differential forms as an aid in exploring some of the less digestible aspects of algebraic topology. Accordingly, we move primarily in the realm of smooth manifolds and use the de Rham theory as a prototype of all of cohomology. For applications to homotopy theory we also discuss by way of analogy cohomology with arbitrary coefficients.

Although we have in mind an audience with prior exposure to algebraic or differential topology, for the most part a good knowledge of linear algebra, advanced calculus, and point-set topology should suffice. Some acquaintance with manifolds, simplicial complexes, singular homology and cohomology, and homotopy groups is helpful, but not really necessary. Within the text itself we have stated with care the more advanced results that are needed, so that a mathematically mature reader who accepts these background materials on faith should be able to read the entire book with the minimal prerequisites.

There are more materials here than can be reasonably covered in a one-semester course. Certain sections may be omitted at first reading without loss of continuity. We have indicated these in the echemstic diagram that follows.

This book is not intended to be foundational; rather, it is only meant to open some of the doors to the formidable edifice of modern algebraic topology. We offer it in the hope that such an informal account of the subject at a semi-introductory level fills a gap in the literature.

It would be impossible to mention all the friends, colleagues, and students whose ideas have contributed to this book. But the senior author author would like on this occasion to express his deep gratitude, first of all to his primary topology teachers E. Specker, N. Steenrod, and
K. Reidemeister of thirty years ago, and secondly to H. Samelson, A. Shapiro, 1. Singer, J.-P. Serre, F. Hirzebruch, A. Borel, J. Milnor, M. Aliyah, S.s. Chern, J. Mather, P. Baum, D. Sullivan. A. Haefliger, and Graeme Segal, who, mostly in collaboration, have continued this word of mouth education to the present; the junior author is indebted to Allen Hatcher for having initiated him into algebraic topology. The reader will find their influence if not in all, then certainly in the more laudable aspects of this book. We also owe thanks to the many other people who have helped with our project: to Ron Donagi, Zbig Fiedorowicz, Dan Freed, Nancy Hingston, and Deane Yang for their reading of various portions of the manuscript and for their critical comments, to Ruby Aguirre, Lu Ann Custer, Barbara Moody, and Caroline Underwood for typing services, and to the staff of Springer-Verlag for its patience, dedication, and skill.

## Introduction

The most intuitively evident topological invariant of a space is the number of connected pieces into which it falls. Over the past one hundred years or so we have come to realize that this primitive notion admits in some sense two higher-dimensional analogues. These are the homotopy and cohomology groups of the space in question.

The evolution of the higher homotopy groups from the component concept is deceptively simple and essentially unique. To describe it, let $\pi_{0}(X)$ denote the set of path components of $X$ and if $p$ is a point of $X$, let $\pi_{0}(X, p)$ denote the set $\pi_{0}(X)$ with the path component of $p$ singled out. Also, corresponding to such a point $p$, let $\Omega_{p} X$ denote the space of maps (continuous functions) of the unit circle $\{z \in \mathbb{C}: \mid \bar{z}\rceil=1\}$ which send 1 to $p$, made into a topological space via the compact open topology. The path components of this so-called loop space $\Omega_{p} X$ are now taken to be the clements of $\pi_{i}(X, p)$ :

$$
\pi_{1}(X, p)=\pi_{0}\left(\Omega_{p} X, \bar{p}\right) .
$$

The composition of loops induces a group structure on $\pi_{1}(X, p)$ in which the constant map $\bar{p}$ of the circle to $p$ plays the role of the identity; so endowed, $\pi_{1}(X, p)$ is called the fundamental group or the first homotopy group of $X$ at $p$. It is in general not Abelian. For instance, for a Riemann surface of genus 3 , as indicated in the figure below:

$\pi_{1}(X, p)$ is generated by six elements $\left\{x_{1}, x_{2}, x_{3}, y_{1}, y_{2}, y_{3}\right\}$ subject to the single relation

$$
\prod_{i=1}^{3}\left[x_{i}, y_{i}\right]=1
$$

where $\left[x_{1}, y_{i}\right]$ denotes the commutator and 1 the identity. The fundamental group is in fact sufficient to classify the closed oriented 2 -dimensional surfaces, but is insufficient in higher dimensions.

To return to the general case, all the higher homotopy groups $\pi_{k}(X, p)$ for $k \geq 2$ can now be defined through the inductive formula:

$$
\pi_{k+2}(X, p)=\pi_{k}\left(\Omega_{p} X, \vec{p}\right)
$$

By the way, if $p$ and $p^{\prime}$ are two points in $X$ in the same path component, then

$$
\pi_{k}(X, p) \simeq \pi_{k}\left(X, p^{\prime}\right)
$$

but the correspondence is not necessarily unique. For the Riemann surfaces such as discussed above, the higher $\pi_{k}$ 's for $k \geq 2$ are all trivial, and it is in part for this reason that $\pi_{1}$ is sufficient to classify them. The groups $\pi_{k}$ for $k \geq 2$ turn out to be Abelian and therefore do not seem to have been taken seriously until the 1930's when W. Hurewicz defined them (in the manner above, among others) and showed that, far from being trivial, they constituted the basic ingredients needed to describe the homotopy-theoretic properties of a space.

The great drawback of these easily defined invariants of a space is that they are very difficult to compute. To this day not all the homotopy groups of say the 2 -sphere, i.e., the space $x^{2}+y^{2}+z^{2}=1$ in $\mathbb{R}^{3}$, have been computed! Nonetheless, by now much is known concerning the general properties of the homotopy groups, largely due to the formidable algebraic techniques to which the "cohomological extension" of the component concept lends itself, and the relations between homotopy and cohomology which have been discovered over the years.

This cohomological extension starts with the dual point of view in which a component is characterized by the property that on it every locally constant function is globally constant. Such a component is sometimes called a connected component, to distinguish it from a path component. Thus, if we define $H^{0}(X)$ to be the vector space of real-valued locally constant functions on $X$, then $\operatorname{dim} H^{0}(X)$ tells us the number of connected components of $X$. Note that on reasonable spaces where path components and connected components agree, we therefore have the formula

$$
\text { cardinality } \pi_{0}(X)=\operatorname{dim} H^{0}(X)
$$

Still the two concepts are dual to each other, the first using maps of the unit interval into $X$ to test for connectedness and the second using maps of $X$
into $\mathbb{R}$ for the same purpose. One further difference is that the cohomology group $H^{0}(X)$ has, by fiat, a natural $\mathbb{R}$-module structure.

Now what should the proper higher-dimensional analogue of $H^{0}(X)$ be? Unfortunately there is no decisive answer here. Many plausible definitions of $H^{k}(X)$ for $k>0$ have been proposed, all with slightly different properties but all isomorphic on "reasonable spaces". Furthermore, in the realm of differentiable manifolds, all these theories conincide with the de. Rham theory which makes its appearance there and constitutes in some sense the most perfect example of a cohomology theory. The de Rham theory is also unique in that it stands at the crossroads of topology, analysis, and physics, enriching all three disciplines.

The gist of the "de Rham extension". is comprehended most easily when $M$ is assumed to be an open set in some Euclidean space $\mathbb{R}^{n}{ }_{2}$ with coordinates $x_{1}, \ldots, x_{n}$. Then amongst the $C^{\infty}$ functions on $M$ the locally popstant ones are precisely those whose gradient

$$
d f=\sum \frac{\partial f}{\partial x_{i}} d x_{i}
$$

vanishes identically. Thus here $H^{0}(M)$ appears as the space of solutions of the differential equation $d f=0$. This suggests that $H^{1}(M)$ should also appear as the space of solutions of some natural differential equations on the manifold $M$. Now consider a 1 -form on $M$ :

$$
\theta=\sum a_{1} d x_{1}
$$

where the $a_{i}$ 's are $C^{\infty}$ functions on $M$. Such an expression can be integrated along a smooth path $\gamma$, so that we may think of $\theta$ as a function on paths $\gamma$ :

$$
\gamma \mapsto \int_{\gamma} \theta
$$

It then suggests itself to seek those $\theta$ which give rise to locally constant functions of $\gamma$, i.e., for which the integral $\int, \theta$ is left unaltered under small variations of $\gamma$-but keeping the endpoints fixed! (Otherwise, only the zero 1 -form would be locaily constant.) Stokes' theorem teaches us that these line integrals are characterized by the differential equations:

$$
\frac{\partial a_{1}}{\partial x_{j}}-\frac{\partial a_{j}}{\partial x_{1}}=0 \quad(\text { written } d \theta=0)
$$

On the other hand, the fundamental theorem of calculus implien that $\int_{y} d f=f(Q)-f(P)$, where $P$ and $Q$ are the endpoints of $\gamma$, so that the gradients are trivally locally constant.

One is here irresistibly led to the definition of $H^{1}(M)$ as the vector space of locally constant line integrals modulo the trivially constant anes. Similarly the higher cohomology groups $H^{k}(M)$ are defined by simply replacing line integrals with their bigher-dimensional analogues, the $k$-yolume integrals

The Grassmann calculus of exterior differential forms facilitates these extensions quite magically. Moreover, the differential equations characterizing the locally constant $k$-integrals are seen to be $C^{\infty}$ invariants and so extend naturally to the class of $C^{\infty}$ manifolds.

Chapter 1 starts with a rapid account of this whole development, assuming little more than the standard notions of advanced calculus, linear algebra and general topology. A nodding acquaintance with singular homology or cohomology helps, but is not necessary. No real familiarity with differential geometry or manifold theory is required. After all, the concept of a manifold is really a very natural and simple extension of the calculus of several variables, as our fathers well knew. Thus for us a manifold is essentially a space constructed from open sets in $\mathbb{R}^{\prime \prime}$ by patching them together in a smooth way. This point of view goes hand in hand with the "computability" of the de Rham theory. Indeed, the decisive difference between the $\pi_{k}$ 's and the $H^{k}$ 's in this regard is that if a manifold $X$ is the union of two open submanifolds $U$ and $V$ :

$$
X=U \cup V
$$

then the cohomology.groups of $U, V, U \cap V$, and $X$ are linked by a much stronger relation than the homotopy groups are. The linkage is expressed by the exactness of the following sequence of linear maps, the MayerVietoris sequence:

starting with $k=0$ and extending up indefinitely. In this sequence every arrow stands for a linear map of the vector spaces and exactness asserts that the kernal of each map is precisely the image of the-preceding one. The horizontal arrows in our diagram are the more or less obvious ones induced by restriction of functions, but the coboundary operator $d^{*}$ is more subtle and uses the existence of a partition of unity subordinate to the coyer $\{U, V\}$ of $X$, that is, smooth functions $\rho_{U}$ and $\rho_{V}$ suct that the first has support in $U$, the second has support in $V$, and $\rho_{U}+\rho_{V} \equiv 1$ on $X$. The simplest relation imaginable between the $H^{k \prime s}$ of $U, V$, and $U \cup V$ would of course be that $H^{k}$ behaves additively; the Mayer-Vietoris sequence teaches us that this is indeed the case if $U$ and $V$ are disjoint. Otherwise, there is a geometric feedback from $H^{k}(U \cap V)$ described by $d^{*}$, and one of the hallmarks of a toplologist is a sound intuition for this $d^{\star}$.

The exactness of the Mayer-Vietoris sequence is our first goal once the basics of the de Rham theory are developed. Thereafter we establish the
second essential property for the computability of the theory, namely that for a smoothly contractible manifold $M$,

$$
H^{k}(M)=\left\{\begin{array}{lll}
R & \text { for } & k=0, \\
0 & \text { for } & k>0 .
\end{array}\right.
$$

This homotopy invariance of the de Rham theory can again be thought of as having evolved from the fundamental theorem of calculus. Indeed, the formula

$$
f(x) d x=d \int_{0}^{x} f(u) d u
$$

shows that every line integral ( 1 -form) on $\mathbf{R}^{\mathbf{1}}$ is a gradient, whence $H^{1}\left(\mathbb{R}^{1}\right)=0$. The homotopy invariance is thus established for the real line. This argument also paves the way for the general case.

The two properties that we have just described constitute a verification of the Eilenberg-Steenrod axioms for the de Rham theory in the present context. Combined with a little geometry, they can be used in a standard manner to compute the cohomology of simple manifolds. Thus, for spheres one finds

$$
H^{k}\left(S^{n}\right)= \begin{cases}R & \text { for } k=0 \text { or } n \\ 0 & \text { otherwise }\end{cases}
$$

while for a Riemann surface $X_{,}$with $g$ holes,

$$
H^{k}\left(X_{\theta}\right)= \begin{cases}\mathbf{R} & \text { for } k=0 \text { or } 2 \\ \mathbf{R}^{2 g} & \text { for } k=1 \\ 0 & \text { otherwise. }\end{cases}
$$

A more systematic treatment in Chapter II leads to the computability proper of the de Rham theory in the following sense. By a finite good cover of $M$ we mean a covering $\mathcal{U}=\left\{U_{\alpha}\right\}_{==1}^{N}$ of $M$ by a finite number of open sets such that all intersections $U_{a 1} \cap \cdots \cap U_{a}$ are either vacuous or contractible. The purely combinatorial data that specify for each subset $\left\{\alpha_{1}, \ldots, \alpha_{k}\right\}$ of $\{1, \ldots, N\}$ which of these two alternatives holds are called the incidence data of the cover. The computability of the theory is the assertion that it can be computed purely from such incidence data. Along lines established in a remarkable paper by André Weil [1], we show this to the the case for the de Rham theory. Weil's point of view constitutes an alternate approach to the sheaf theory of Leray and was influential in Cartan's theorie des carapaces. The beauty of his argument is that it can be read both ways: either to prove the computability of de Rham or to prove the topological invariance of the combinatorial prescription.

To digress for a moment, it is difficult not to speculate about what kept Poincare from discovering this argument forty years earlier. One has the feeling that he already knew every step along the way. After all, the homotopy invariance of the de Rham theory for $\mathbf{R}^{\mathbf{n}}$ is known as the Poincare
lemma! Nevertheless, he veered sharply from this point of view, thinking predominantly in terms of triangulations, and so he in fact was never able to prove either the computability of de Rham or the invariance of the combinatorial definition. Quite possibly the explanation is that the whole $C^{\infty}$ point of view and, in particular, the partitions of unity were alien to him and his contemporaries, steeped as they were in real or complex analytic questions.

De Rham was of course the first to prove the topological invariance of the theory that now bears his name. He showed that it was isomorphic to the singular cohomology, which is trivially-i.e., by definition-topologically invariant. On the other hand, André Weil's approach relates the de Rham theory to the Cech theory, which is again topologically invariant.

But to return to the plan of our book, the bulk of Chapter I is actually devoted to explaining the fundamental symmetry in the cohomology of a compact oriented manifold. In its most primitive form this symmetry asserts that

$$
\operatorname{dim} H^{q}(M)=\operatorname{dim} H^{n-q}(M)
$$

Poincare seems to have immediately realized this consequence of the locally Euclidean nature of a manifold. He saw it in terms of dual subdivisions, which turn the incidence relations upside down. In the de Rham theory the duality derives from the intrinsic pairing between differential forms of arbiItrary and compact support. Indeed consider the de Rham theory of $\mathbb{R}^{1}$ with compactly supported forms. Clearly the only function with compact support on $R^{1}$ is the zero function. As for 1 -forms, not every 1 -form $g d x$ is now a gradient of a compactly supported function $f$; this happens if and only if $\int_{-\infty}^{\infty} g d x=0$. Thus we see that the compactly supported de Rham theory of $\mathbb{R}^{1}$ is given by

$$
H_{c}^{k}\left(\mathbb{R}^{1}\right)= \begin{cases}0 & \text { for } k=0 \\ \mathbb{R} & \text { for } k=1\end{cases}
$$

and is just the de Rham theory "upside down." This phenomenon now extends inductively to $\mathbb{R}^{n}$ and is finally propagated via the Mayer-Vietoris sequence to the cohomology of any compact oriented manifold.

One virtue of the de Rham theory is that the essential mechanism of this duality is via the familiar operation of integration, coupled with the natural ring structure of the theory: a $p$-form $\theta$ can be multiplied by a $q$-form $\phi$ to produce a $(p+q)$-form $\theta \wedge \phi$. This multiplication is "commutative in the graded sense":

$$
\theta \wedge \phi=(-1)^{p q} \phi \wedge \theta
$$

(By the way, the commutativity of the de Rham theory is another reason why it is more "perfect" than its other more general 'orethren, which become commutative only on the cohomology level.) In particular, if $\phi$ has compact support and is of dimension $n-p$, where $n=\operatorname{dim} M$, then inte-
gration over $\boldsymbol{M}$ gives rise to a pairing

$$
(\theta, \phi) \rightarrow \int_{M} \theta \wedge \phi
$$

which descends to cohomology and induces a pairing $\qquad$

$$
H^{p}(M) \otimes H_{c}^{n-p}(M) \rightarrow \mathbf{R}
$$

A more sophisticated version of Poincare duality is then simply that the pairing above is dual; that is, it establishes the two spaces as duals of each other.

Although we return to Poincaré duality over and over again throughout the book, we have not attempted to give an exhaustive treatment. (There is, for instance, no mention of Alexander duality or other phenomena dealing with relative, rather than absolute, theory.) Instead, we chose to spend much time bringing Poincaréduality to life by explicitly constructing the Poincare dual of a submanifold $N$ in $M$. The problem is the following. Suppose $\operatorname{dim} N=k$ amd $\operatorname{dim} M=n$, both being compact oriented. Integration of a $k$-form $\omega$ on $M$ over $N$ then defines a linear functional from $H^{k}(M)$ to $\mathbb{R}$, and so, by Poincaré duality, must be represented by a cohomology class in $H^{n-k}(M)$. The question is now: how is one to construct a representative of this Poincaré dual for $N$, and can such a representative be made to have support arbitrarily close to $N$ ?

When $N$ reduces to a point $p$ in $M$, this question is easily answered. The dual of $p$ is represented by any $n$-form $\omega$ with support in the component $M_{\text {, }}$ of $p$ and with total mass 1 , that is, with

$$
\int_{M_{p}} \omega=1
$$

Note also that such an $\omega$ can be found with support in an arbitrarily small neighborhood of $p$, by simply choosing coordinates on $M$ centered at $p$, say $x_{1}, \ldots, x_{n}$, and setting

$$
\omega=\lambda(x) d x_{1} \ldots d x_{n}
$$

with $\lambda$ a bump function of mass 1 . (In the limit, thinking of Dirac's $\delta$-function as the Poincare dual of $p$ leads us to de Rham's theory of currents.)

When the point $\dot{p}$ is replaced by a more general submanifold $N$, it is easy to extend this argument, provided $N$ has a product neighborhood $D(N)$ in $M$ in the sense that $D(N)$ is diffeomorphic to the product $N \times D^{n-k}$, where $D^{n-k}$ is a disk of the dimension indicated. However, this need not be the case! Just think of the center circle in a Möbius band. Its neighborhoods are at best smaller Möbius bands.

In the process of constructing the Poincare dual we are thus confronted by the preliminary question of how to measure the possible twistings of neighborhoods of $N$ in $M$ and to correct for the twist. This is a subject in its own right nowadays, but was initiated by H. Whitney and H. Hopf in just
the present context during the Thirties and Forties. Its trade name is fiber bundle theory and the cohomological measurements of the global twist in such "local products" as $D(N)$ are referred to as characteristic classes. In the last forty years the theory of characteristic classes has grown to such an extent that we cannot do it justice in our book. Still, we hope to have covered it sufficiently so that the reader will be able to see its ramifications in both differential geometry and topology. We also hope that our account could serve as a good introduction to the connection between characteristic classes and the global aspects of the gauge theories of modern physics.

That a connection between the equations of mathematical physics and topology might exist is not too surprising in view of the classical theory of electricity. Indeed, in a vacuum the electromagnetic field is represented by a 2 -form in the $(x, y, z, t)$-space:

$$
\omega=\left(E_{x} d x+E_{y} d y+E_{z} d z\right) d t+H_{x} d y d z-H_{y} d x d z+H_{z} d x d y
$$

and the form $\omega$ is locally constant in our sense, i.e., $d \omega=0$. Relative to the Lorentz metric in $\mathbb{R}^{4}$ the star of $\omega$ is defined to be

$$
{ }^{*} \omega=-\left(H_{x} d x+H_{y} d y+H_{z} d z\right) d t+E_{x} d y d z-E_{y} d x d z+E_{z} d x d z
$$

and Maxwell's equations simply assert that both $\omega$ and its star are closed: $d \omega=0$ and $d * \omega=0$. In particular, the cohomology class of $* \omega$ is a well defined object and is often of physical interest.

To take the simplest example, consider the Coulomb potential of a point charge $q$ at rest in the origin of our coordinate system. The field $\omega$ generated by this charge then has the description

$$
\omega=-d\left(\frac{1}{r} \cdot d t\right)
$$

with $r=\left(x^{2}+y^{2}+z^{2}\right)^{1 / 2} \neq 0$. Thus $\omega$ is defined on $R^{4}-R_{t}$, where $R_{1}$ denotes the $t$-axis. The de Rham cohomology of this set is easily computed to be

$$
H^{k}\left(R^{4}-R_{i}\right)= \begin{cases}R & \text { for } k=0,2 \\ 0 & \text { otherwise. }\end{cases}
$$

The form $\omega$ is manifestly cohomologically uninteresting, since it is $d$ of a 1 -form and so is trivially "closed", i.e., locally constant. On the other hand the * of $\omega$ is given by

$$
* \omega=\frac{q}{4 \pi} \frac{x d y d z-y d x d z+z d x d y}{r^{3}}
$$

(which turns out to generate $H^{2}$. The cohomology class of * $\omega$ can thus be interpreted as the charge of our source.

In seeking differential equations for more sophisticated phenomena than electricity, the modern physicists were led to equations (the Yang-Mills) which fit perfectly into the framework of characteristic classes as developed by such masters as Pontrjagin and Chern during the Fortics.

Having sung the praises of the de Rham theory, it is now time to admit its limitations. The trouble with it, is that it only tells part of the cohomology story and from the point of view of the homotopy theorists, only the simplest part. The de Rham theory ignores torsion phenomena. To explain this in a little more detail, recall that the homotopy groups do not behave well under the union operation. However, they behave very well under ${ }^{\top}$ Cartesian products. Indeed, as is quite easily shown,

$$
\pi_{d}(X \times Y)=\pi_{d}(X) \oplus \pi_{d}(Y)
$$

More generally, consider the situation of a fiber bundle (twisted product). Here we are dealing with a space $E$ mapped onto a space $X$ with the fibers-i.e., the inverse images of points - all homeomorphic in some uniform sense to a fixed space $Y$. For fiber bundles, the additivity of $\pi_{k}$ is stretched into an infinite exact sequence of Mayer-Vietoris type; however now going in the opposite direction:

$$
\cdots \rightarrow \pi_{d}(Y) \rightarrow \pi_{d}(E) \rightarrow \pi_{d}(X) \rightarrow \pi_{d-1}(Y) \rightarrow \cdots
$$

This phenomenon is of course fundamental in studying the twist we talked about earlier, but it also led the homotopy theorists to the conjecture that in their much more flexible Homotopy category, where objects are considered equal if they can be deformed into each other, every space factors into a twisted product of irreducible prime factors. This turns out to be true and is called the Postnikov decomposition of the space. Furthermore, the "prime spaces" in this context all have nontrivial homotopy groups in only one dimension. Now in the homotopy category such a prime space, say with nontrivial homotopy group $\pi$ in dimension $n$, is determined uniquely by $\pi$ and $n$ and is denoted $K(\pi, n)$. These $K(\pi, n)$-spaces of Eilenberg and MacLane therefore play an absolutely fundamental role in homotopy theory. They behave well under the standard group operations. In particular, corresponding to the usual decomposition of a finitely generated Abelian group:

$$
\pi=\left(\underset{p}{\left.\bigoplus_{p} \pi^{(p)}\right) \oplus \mathbf{Z}^{\prime}, ~ . ~}\right.
$$

into p-primary parts and a free part (said to correspond to the prime at infinity), the $K(\pi, n)$ will factor into a product

$$
K(\pi, n)=\left(\prod_{p} K\left(\pi^{(p)}, n\right)\right) \cdot K(\mathbb{Z}, n)^{v}
$$

It follows that in homotopy theory, just as in many questions of number theory, one can work one prime at a time. In this framework it is now quite easy to explain the shortcomings of the de Rham theory: the theory is sensitive only to the prime at infinity!

After having encountered the Cech theory in Chapter II, we make in Chapter III the now hopefully easy transition to cohomology with coefficients in an arbitrary Abelian group. This theory, say with coefficients in the
integers, is then sensitive to all the p-primary phenomena in homotopy theory.

The development sketched here is discussed in greater detail in Chapter III, where we also apply the ideas to the computation of some relatively simple homotopy groups. All these computations in the final analysis derive from Serre's brilliant idea of applying the spectral sequence of Leray to homotopy problems and from his coining of a sufficiently general definition of a twisted product, so that, as the reader will see, the Postnikov decomposition in the form we described it, is a relatively simple matter. It remains therefore only to say a few words to the uninitiated about what this "spectral sequence" is.

We remarked earlier that homotopy behaves additively under products. On the other hand, cohomology does not. In fact, neglecting matters of torsion, i.e., reverting to the de Rham theory, one has the Künneth formula:

$$
H^{k}(X \times Y)=\sum_{p+q=k} H^{p}(X) \otimes H^{q}(Y)
$$

The next question is of course how cohomology behaves for twisted products. It is here that Leray discovered some a priori bounds on the extent and manner in which the Künneth formula can fail due to a twist. 'For instance, one of the corollaries of his spectral sequence is that if $X$ and $Y$ have vanishing cohomology in positive dimensions less than $p$ and $q$ respectively, then however one twists $X$ with $Y$, the Künneth formula will hold up to dimension $d<\min (p, q)$.

Armed with this sort of information, one can first of all compute the early part of the cohomology of the $K(\pi, n)$ inductively, and then deduce which $K(\pi, n)$ must occur in a Postnikov decomposition of $X$ by comparing the cohomology on both sides. This procedure is of course ąt best ad hoc, and therefore gives us only fragmentary results. Still, the method points in the right direction and can be codified to prove the computability (in the logical sense) of any particular homotopy group, of a sphere, say. This theorem is due to E. Brown in full generality. Unfortunately, however, it is not directly applicable to explicit calculations-even with large computing machines.

So far this introduction has been written with a lay audience in mind. We hope that what they have read has made sense and has whetted their appetities. For the more expert, the following summary of the plan of our book might be helpful.

In Chapter I we bring out from scratch Poincaré duality and its various extensions, such as the Thom isomorphism, all in the de Rham category. Along the way all the axioms of a cohomology theory are encountered, but at first treated only in our restricted context.

In Chapter II we introduce the techniques of spectral sequences as an extension of the Mayer-Vietoris principle and so are led to A. Weil's Cech-de Rham theory. This theory is later used as a bridge to cohomology
in general and to integer cohomology in particular. We spend considerable time patching together the Euler class of a sphere bundle and exploring its relation to Poincare duality. We also very brizfly present the sheaf-theoretic proof of this duality.

In Chapter III we come to grips with spectral sequences in a more formal manner and describe some of their applications to homotopy theory, for example, to the computation of $\pi_{s}\left(S^{3}\right)$. This chapter is less self-contained than the others and is meant essentially as an introduction to homotopy theory proper. In the same spirit we close with a short account of Sullivan's rational homotopy theory.

Finally, in Chapter IV we use the Grothendieck approach towards characteristic classes to give a more or less self-contained treatment of Chern and Pontrjagin classes. We then relate them to the cohomology of the infinite Grassmannian.

Unfortunately there was no time left within the scope of our book to explain the functorial approach to classifying spaces in general and to make the connection with the Eilenberg-MacLane spaces. We had to relegate this material, which is most naturally explained in the framework of semisimplicial theory, to a mythical second volume. The novice should also be warned that there are all too many other topics which we have not mentioned. These include generalized cohomology theories, cohomology operations, and the Adams and Eilenberg-Moore spectral sequences. Alas, there is also no mention of the truly geometric achievements of modern topology, that is, handlebody theory, surgery theory, and the structure theory of differentiable and piecewise linear manifolds. Still, we hope that our volume serves as an introduction to all this as well as to such topics in analysis as Hodge theory and the Atiyah-Singer index theorems for elliptic differenital operators.

## CHAPTER I

## de Rham Theory

## §1 The de Rham Complex on $\mathbb{R}^{n}$

To start things off we define in this section the de Rham cohomology and compute a few examples. This will turn out to be the most important diffeomorphism invariant of a manifold. So let $x_{1}, \ldots, x_{n}$ be the linear coordinates on $\mathbb{R}^{\mathbf{n}}$. We define $\mathbf{\Omega}^{*}$ to be the algebra over $\mathbf{R}$ generated by $d x_{1}, \ldots, d x_{n}$ with the relations

$$
\left\{\begin{array}{l}
\left(d x_{i}\right)^{2}=0 \\
d x_{i} d x_{j}=-d x_{j} d x_{i}, i \neq j
\end{array}\right.
$$

As a vector space over $R, \Omega^{*}$ has basis

$$
\begin{gathered}
1, d x_{i}, d x_{i} d x_{j}, d x_{i} d x_{j} d x_{k}, \ldots, d x_{1} \ldots d x_{n} . \\
i<j<k
\end{gathered}
$$

The $C^{\infty}$ differential forms on $\mathbf{R}^{n}$ are elements of

$$
\underbrace{\Omega^{*}\left(R^{n}\right)}=\left\{C^{\infty} \text { functions on } \mathbb{R}^{n}\right\} \bigotimes_{R} \Omega^{*}
$$

Thus, if $\omega$ is such a form, then $\omega$ can be uniquely written as $\sum f_{i_{2}} \cdots{ }_{6}$ $d x_{i_{1}} \ldots d x_{i_{6}}$ where the coefficients $f_{i_{1}} \ldots y_{4}$ are $C^{\infty}$ functions. We also write $\omega=\sum f_{1} d x_{1}$. The algebra $\Omega^{*}\left(\mathbf{R}^{\prime \prime}\right)=\Phi^{i}=0 \Omega^{*}\left(\mathbf{R}^{\eta}\right)$ is naturally graded, where $\Omega^{d}\left(\mathbb{R}^{n}\right)$ consists of the $C^{\infty}, q$-forms on $\mathbb{R}^{\prime \prime}$. There is a differential operator

$$
d: \Omega^{q}\left(\mathbf{R}^{\prime}\right) \rightarrow \boldsymbol{\Omega}^{+1}\left(\mathbf{R}^{\prime}\right)
$$

defined as follows:
i) if $f \in \Omega^{0}\left(R^{\prime \prime}\right)$, then $d f=\sum \partial f / \partial x_{i} d x_{i}$
ii) if $\omega=\sum f_{I} d x_{l}$, then $d \omega=\sum d f_{I} d x_{I}$.

Example 1.1. If $\omega=x d y$, then $d \omega=d x d y$.
This $d$, called the exterior differentiation, is the ultimate abstract extension of the usual gradient, curl, and divergence of vector calculus on $\mathbb{R}^{\mathbf{3}}$, as the example below partially illustrates.

EXAMPLE 1.2. On $R^{3}, \Omega^{0}\left(R^{3}\right)$ and $\Omega^{3}\left(\mathbb{R}^{3}\right)$ are each 1-dimensional and $\Omega^{1}\left(R^{3}\right)$ and $\Omega^{3}\left(\mathbb{R}^{3}\right)$ are each 3-dimensional over the $C^{\infty}$ functions, so the following identifications are possible:

$$
\begin{array}{ccc}
\{\text { functions }\} & \simeq\{0 \text {-forms }\} & \simeq\{\text { \{3-forms }\} \\
f & \leftrightarrows & \leftrightarrows
\end{array}
$$

and

$$
\begin{aligned}
& \text { \{vector fields }\} \simeq \quad\{1 \text {-forms }\} \\
& X=\left(f_{1}, f_{2}, f_{3}\right) \leftrightarrow f_{1} d x+f_{2} d y+f_{3} d z \leftrightarrow f_{1} d y d z-f_{2} d x d z+f_{3} d x d y
\end{aligned}
$$

On functions,

$$
d f=\frac{\partial f}{\partial x} d x+\frac{\partial f}{\partial y} d y+\frac{\partial f}{\partial z} d z
$$

On 1-forms,
$d\left(f_{1} d x+f_{2} d y+f_{3} d z\right)$

$$
=\left(\frac{\partial f_{3}}{\partial y}-\frac{\partial f_{2}}{\partial z}\right) d y d z-\left(\frac{\partial f_{1}}{\partial z}-\frac{\partial f_{3}}{\partial x}\right) d x d z+\left(\frac{\partial f_{2}}{\partial x}-\frac{\partial f_{1}}{\partial y}\right) d x d y
$$

On 2-forms,

$$
d\left(f_{1} d y d z-f_{2} d x d z+f_{3} d x d y\right)=\left(\frac{\partial f_{1}}{\partial x}+\frac{\partial f_{2}}{\partial y}+\frac{\partial f_{3}}{\partial z}\right) d x d y d z
$$

In summary,

$$
\left\{\begin{aligned}
d(0 \text {-forms }) & =\text { gradient } \\
& d(1 \text {-forms })=\text { curl } \\
d(2 \text {-forms }) & =\text { divergence } .
\end{aligned}\right.
$$

The wedge product of two differential forms, written $\tau \wedge \omega$ or $\tau \cdot \omega$, is defined as follows: if $\tau=\sum f_{I} d x_{I}$ and $\omega=\sum g_{J} d x_{j}$, then

$$
\tau \wedge \omega=\sum f_{I} g_{J} d x_{I} d x_{J}
$$

Note that $\tau \wedge \omega=(-1)^{\operatorname{degr} \operatorname{deg} \omega} \omega \wedge \tau$.
Proposition 1.3. $d$ is an antiderivation, i.e.,

$$
d(\tau \cdot \omega)=(d \tau) \cdot \omega+(-1)^{\text {degt } \tau \cdot d \omega}
$$

Proof. By linearity it suffices to check on monomials

$$
\begin{aligned}
& \tau=f_{I} d x_{I}, \omega=g_{J} d x_{J} \\
& d(\tau \cdot \omega)=d\left(f_{I} g_{J}\right) d x_{I} d x_{J}=\left(d f_{I}\right) g_{J} d x_{I} d x_{J}+f_{I} d g_{J} d x_{I} d x_{J} \\
&=(d \tau) \cdot \omega+(-1)^{\operatorname{deg\tau } \tau \cdot d \omega .}
\end{aligned}
$$

On the level of functions $d(f g)=(d f) g+f(d g)$ is simply the ordinary product rule.

Proposition 1.4, $d^{2}=0$.
Proof. This is basically a consequence of the fact that the mixed partials are equal. On functions,

$$
d^{2} f=d\left(\sum_{i} \frac{\partial f}{\partial x_{i}} d x_{i}\right)=\sum_{i, j} \frac{\partial^{2} f}{\partial x_{j} \partial x_{i}} d x_{j} d x_{i}
$$

Here the factors $\partial^{2} f / \partial x_{j} \partial x_{i}$ are symmetric in $i, j$ while $d x_{j} d x_{i}$ are skewsymmetric in $i, j$; hence $d^{2} f=0$. On forms $\omega=f_{1} d x_{I}$,

$$
d^{2} \omega=d^{2}\left(f_{I} d x_{I}\right)=d\left(d f_{I} d x_{1}\right)=0
$$

by the previous computation and the antiderivation property of $d$.
1 The complex $\Omega^{*}\left(\mathbf{R}^{*}\right)$ together with the differential operator $d$ is called the de Rham complex on $R^{n}$. The kernel of $d$ are the closed forms and the image of $d$, the exact forms. The de Rham complex may be viewed as a God-given set of differential equations, whose solutions are the closed forms. For instance, finding a closed 1 -form $f d x+g d y$ on $R^{2}$ is tantamount to solving | the differential equation $\partial g / \partial x-\partial f / \partial y=0$. By Proposition 1.4 the exact forms are automatically closed; these are the trivial or "uninteresting" solutions. A measure of the size of the space of "interesting" solutions is the definition of the de Rham cohomology.

Definition. The $\boldsymbol{q}$-th de Rham cohomology of $\mathbb{R}^{\mathbf{n}}$ is the vector space

$$
H_{D R}^{e}\left(\mathbb{R}^{*}\right)=\{\text { closed } q \text {-forms }\} /\{\text { exact } q-\text { forms }\} .
$$

We sometimes suppress the subscript $D R$ and write $H^{q}\left(R^{*}\right)$. If there is a need to distinguish between a form $\omega$ and its cohomology class, we denote the latter by $[\omega]$.

Note that all the definitions so far work equally well for any open subset $\boldsymbol{U}$ of $\mathbf{R}^{\boldsymbol{n}}$; for instance,

$$
\Omega^{*}(U)=\left\{C^{\infty} \text { functions on } U\right\} \bigotimes_{\Omega} \Omega^{*}
$$

So we may also speak of the de Rham cohomology $H_{D}{ }_{D}(U)$ of $U$.

Examples 1.5.
(a) $n=0$

$$
H^{\mathrm{q}}=\left\{\begin{array}{cc}
R & q=0 \\
0 & q>0
\end{array}\right.
$$

(b) $n=1$

Since (ker $d$ ) $\cap \Omega^{\mathbf{0}}\left(\mathbf{R}^{\mathbf{1}}\right)$ are the constant functions,

$$
H^{0}\left(\mathbf{R}^{1}\right)=\mathbf{R}
$$

On $\Omega^{1}\left(R^{1}\right)$, ker $d$ are all the 1 -forms.
If $\omega=g(x) d x$ is a 1 -form, then by taking

$$
f=\int_{0}^{x} g(u) d u
$$

we find that

$$
d f=g(x) d x
$$

Therefore every 1 -form on $\mathbb{R}^{1}$ is exact and

$$
H^{1}\left(\mathbb{R}^{1}\right)=0
$$

(c) Let $U$ be a disjoint union of $m$ open intervals on $\mathbb{R}^{1}$.

Then

$$
H^{0}(U)=\mathbf{R}^{m}
$$

and

$$
H^{1}(U)=0 .
$$

(d) In general

$$
H^{*}\left(\mathbb{R}^{n}\right)= \begin{cases}\mathbb{R} & \text { in dimension } 0 \\ 0 & \text { otherwise }\end{cases}
$$

This result is called the Poincaré lemma and will be proved in Section 4.
The de Rham complex is an example of a differential complex. For the convenience of the reader we recall here some basic definitions and results on differential complexes. A direct sum of vector spaces $C=\oplus_{\text {eiz }} C^{4}$ indexed by the integers is called a differential complex if there are homomorphisms

$$
\cdots \longrightarrow C^{q-1} \xrightarrow{d} C^{q} \xrightarrow{d} C^{q+1} \longrightarrow \cdots
$$

such that $d^{2}=0 . d$ is the differential operator of the complex $C$. The cohomology of $C$ is the direct sum of vector spaces $H(C)=\bigoplus_{q \in 2} H^{4}(C)$, where

$$
H^{q}(C)=\left(\text { ker } d \cap C^{9}\right) /\left(\operatorname{im} d \cap C^{\top}\right)
$$

A map $f: A \rightarrow B$ between two differential complexes is a chain map if it commutes with the differential operators of $A$ and $B: f d_{A}=d_{B} f$.

A sequence of vector spaces

$$
\cdots \longrightarrow V_{i-1} \xrightarrow{f_{i-1}} V_{1} \xrightarrow{f_{1}} V_{t+1} \longrightarrow \cdots
$$

is said to be exact if for all $i$ the kernel of $f_{1}$ is equal to the image of its predecessor $f_{i-1}$. An exact sequence of the form

$$
0 \longrightarrow A \longrightarrow B \longrightarrow C \longrightarrow 0
$$

is called a short exact sequence. Given a short exact sequence of differential complexes

$$
0 \longrightarrow A \xrightarrow{s} B \longrightarrow 0
$$

in which the maps $f$ and $g$ are chain maps, there is a long exact sequence of cohomology groups

In this sequence $f^{*}$ and $g^{*}$ are the naturally induced maps and $d^{*}[c]$, $c \in C^{4}$, is obtained as follows:

By the surjectivity of $g$ there is an element $b$ in $B^{9}$ such that $g(b)=c$. Because $g(d b)=d(g b)=d c=0, d b=f(a)$ for some $a$ in $A^{4+1}$. This $a$ is easily checked to be closed. $d^{*}[c]$ is defined to be the cohomology class [a] in $H^{++1}(A)$. A simple diagram-chasing shows that this definition of $d^{*}$ is independent of the choices made.

Exercise. Show that the long exact sequence of cohomology groups exists and is exact. (If you are stuck, see, for instance, MacLane [1, Ch. II, Th. 4.1, p. 45].)

## Compact Supports

A slight modification of the construction of the preceding section will give us another diffeomorphism invariant of a manifold. For now we again
restrict our attention to $\mathbb{R}^{n}$. Recall that the support of a continuous function $f$ on a topological space $X$ is the smallest closed set on which $f$ is not zero, i.e., Supp $f=\{p \in X \mid f(p) \neq 0\}$. If in the definition of the de Rham complex we use only the $C^{\infty}$ functions with compact support, the resulting complex is called the de Rham complex $\mathbf{\Omega}_{*}^{*}\left(\mathbb{R}^{\prime}\right)$ with compact supports:
$\Omega_{c}^{*}\left(\mathbb{R}^{n}\right)=\left\{C^{\infty}\right.$ functions on $\mathbb{R}^{n}$ with compact support $\} \bigotimes_{R} \Omega^{*}$.

## Example 1.6.

(a) $H_{c}^{*}($ point $)= \begin{cases}R & \text { in dimension } 0, \\ 0 & \text { elsewhere } .\end{cases}$
(b) The compact cohomology of $\mathbf{R}^{\mathbf{2}}$. Again the closed 0-forms are the constant functions. Since there are no constant functions on $\mathbf{R}^{\mathbf{1}}$ with compact support,

$$
H_{c}^{0}\left(\mathbf{R}^{1}\right)=0
$$

To compute $H_{c}^{1}\left(\mathbb{R}^{1}\right)$, consider the integration map

$$
\int_{\mathbb{R}^{1}}: \Omega_{c}^{1}\left(\mathbb{R}^{1}\right) \longrightarrow \mathbb{R}^{1}
$$

This map is clearly surjective. It vanishes on the exact 1 -forms $d f$ where $f$ has compact support, for if the support of $f$ lies in the interior of $[a, b]$, then

$$
\int_{\mathbb{R}^{1}} \frac{d f}{d x} d x=\int_{a}^{b} \frac{d f}{d x} d x=f(b)-f(a)=0
$$

If $g(x) d x \in \Omega_{c}^{1}\left(\mathbb{R}^{1}\right)$ is in the kernel of the integration map, then the function

$$
f(x)=\int_{-\infty}^{x} g(u) d u
$$

will have compact support and $d f=g(x) d x$. Hence the kernel of $\int_{R^{1}}$ are precisely the exact forms and

$$
H_{c}^{1}\left(\mathbb{R}^{1}\right)=\frac{\Omega_{c}^{1}\left(\mathbb{R}^{1}\right)}{\operatorname{ker} \int_{\mathbb{R}^{1}}}=\mathbb{R}^{1}
$$

Remark. If $g(x) d x \in \Omega_{c}^{1}\left(\mathbb{R}^{1}\right)$ does not have total integral 0 , then

$$
f(x)=\int_{-\infty}^{x} g(u) d u
$$

will not have compact support and $g(x) d x$ will not be exact.
(c) More generally,

$$
H_{c}^{*}\left(\mathbb{R}^{n}\right)= \begin{cases}\mathbb{R} & \text { in dimension } n \\ 0 & \text { otherwise. }\end{cases}
$$

This result is the Poincaré lemma for cohomology with compact support and will be proved in Section 4.

Exercise 1.7. Compute $H_{D R}^{*}\left(\mathbb{R}^{2}-P-Q\right)$ where $P$ and $Q$ are two points in $\mathbb{R}^{2}$. Find the closed forms that represent the cohomology classes.

## §2 The Mayer-Vietoris Sequence

In this section we extend the definition of the de, Rham cohomology frato $\mathbb{R}^{n}$ to any differentiable manifold and introduce a basic technique for 0 om puting the de Rham cohomology, the Mayer-Vietoris sequence. But first we have to discuss the functorial nature of the de Rham complex.

## The Functor $\Omega^{*}$

Let $x_{1}, \ldots, x_{m}$ and $y_{1}, \ldots, y_{n}$ be the standard coordinates on $\mathbf{R}^{m}$ and $\mathbb{R}^{n}$, respectively. A smooth map $f: \mathbb{R}^{m} \rightarrow \mathbb{R}^{n}$ induces a pullback map on $C^{\infty}$ functions $f^{*}: \boldsymbol{\Omega}^{0}\left(\mathbb{R}^{n}\right) \rightarrow \mathbf{\Omega}^{0}\left(\mathbb{R}^{m}\right)$ via

$$
f^{*}(g)=g \circ f .
$$

We would like to extend this pullback map to all forms $f^{*}: \Omega^{*}\left(\mathbb{R}^{n}\right) \rightarrow$ $\Omega^{*}\left(\mathbb{R}^{m}\right)$ in such a way that it commutes with $d$. The commutativity with $d$ defines $f^{*}$ uniquely:

$$
f^{*}\left(\sum g_{t} d y_{i_{1}} \ldots d y_{l_{0}}\right)=\sum\left(g_{t} \circ f\right) d f_{i_{1}} \ldots d f_{i_{4}},
$$

where $f_{i}=y_{i} \circ f$ is the $i$-th component of the function $f$.
Proposition 2.1. With the above definition of the pullback map $f^{*}$ an-forms, $f^{*}$ commutes with d.

Proof. The proof is essentially an application of the chain rule.

$$
\begin{aligned}
d f^{*}\left(g_{1} d y_{i_{1}} \ldots d y_{i_{4}}\right) & \left.\left.=d\left(g_{1} \circ f\right)\right) d f_{i_{1}} \ldots d f_{i_{0}}\right)=d\left(g_{1} \circ f\right) d f_{i_{1}} \ldots d f_{i_{2}} \\
\hat{f}^{*} d\left(g_{1} d y_{i_{1}} \ldots d y_{i_{0}}\right) & =f^{*}\left(\frac{\partial g_{t}}{\partial y_{i}} d y_{l} d y_{i_{1}} \ldots d y_{i_{4}}\right) \\
& =\left(\left(\frac{\partial g_{l_{1}}}{\partial y_{i}} \circ f\right) d f_{i}\right) d f_{i_{1}} \ldots d f_{i_{4}} \\
& =d\left(g_{1} \circ f\right) d f_{i_{1}} \ldots d f_{i_{4}}
\end{aligned}
$$

Let $x_{1}, \ldots, x_{n}$ be the standard coordinate system and $u_{1}, \ldots u_{n}$ a new coordinate system on $\mathbb{R}^{n}$, i.e., there is a diffeomorphism $f: \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$ such that $u_{i}=x_{i} \circ f=f^{*}\left(x_{i}\right)$. By the chain rule, if $g$ is a smooth function on $\mathbb{R}^{n}$, then

$$
\sum_{i} \frac{\partial g}{\partial u_{i}} d u_{i}=\sum_{i, j} \frac{\partial g}{\partial u_{i}} \frac{\partial u_{i}}{\partial x_{j}} d x_{j}=\sum_{j} \frac{\partial g}{\partial x_{j}} d x_{j}
$$

So dg is independent of the coordinate system.
$\left\lvert\,-\frac{\text { Exercise 2.h.l. More generally show that if } \omega=\sum g_{I} d u_{I}, \text { then } d \omega=\sum d g_{1},}{d u_{I}}\right.$.
Thus the exterior derivative $d$ is independent of the coordinate system on $\mathbb{R}^{\prime \prime}$.

Recall that a category consists of a class of ebjects and for any two objects $A$ and $B$, a set $\operatorname{Hom}(A, B)$ of morphisms from $A$ to $B$, satisfying the following properties. If $f$ is a morphism from $A$ to $B$ and $g$ a morphism from $B$ to $C$, then the composite morphism $g \circ f$ from $A$ to $C$ is defined; furthermore, the composition operation is required to be associative and to have an identity $1_{A}$ in $\operatorname{Hom}(A, A)$ for every object $A$. The class of all groups together with the group homomorphisms is an example of a category.

A covariant functor $F$ from a category $\mathscr{X}$ to a catefory $\mathscr{L}$ associates to every object $A$ in $\mathscr{X}$ an object $F(A)$ in $\mathscr{L}$, and every morphism $f: A \rightarrow B$ in $\mathscr{X}$ a morphism $F(f): F(A) \rightarrow F(B)$ in $\mathscr{L}$ such that $F$ preserves composition and the identity:

$$
\begin{aligned}
F(g \circ f) & =F(g) \circ F(f) \\
F\left(1_{A}\right) & =1_{F(\Lambda)}
\end{aligned}
$$

If $F$ reverses the arrows, i.e., $F(f): F(B) \rightarrow F(A)$, it is said to be a contravariant functor.

In this fancier language the discussion above may be summarized as follows: $\Omega^{*}$ is a contravariant functor from the category of Euclidean spaces $\left\{\mathbb{R}^{n}\right\}_{n \in Z}$ and smooth maps: $\mathbf{R}^{m} \rightarrow \mathbb{R}^{n}$ to the category of commutative differential graded algebras and their homomorphisms. It is the unique such functor that is the pullback of functions on $\Omega^{0}\left(\mathbb{R}^{n}\right)$. Here the commutativity of the graded algebra refers to the fact that

$$
\tau \omega=(-1)^{\operatorname{deg} \mathrm{t} \operatorname{det} \omega} \omega \tau
$$

The functor $\Omega^{*}$ may be extended to the category of differentiable manifolds. For the fundamentals of manifold theory we recommend de Rham [1, Chap. 1]. Recall that a differentiable structure on a manifold is given by an atlas, i.e., an open cover $\left\{U_{a}\right\}_{\alpha \in A}$ of $M$ in which each open set $U_{a}$ is homeomorphic to $\mathbb{R}^{\mathbf{n}}$ via a homeomorphism $\phi_{a}: U_{a} \simeq \mathbb{R}^{\mathbf{n}}$, and on the overlaps $U_{a} \cap U_{p}$ the transition functions

$$
g_{\alpha \beta}=\phi_{a} \circ \phi_{\beta}^{-1}: \phi_{\alpha}\left(U_{a} \cap U_{\beta}\right) \rightarrow \phi_{\alpha}\left(U_{a} \cap U_{\beta}\right)
$$

/ are diffeomorphisms of open subsets of $\mathbf{R}^{n}$; furthermore, the atlas is required to be maximal with respect to inclusions. All manifolds will be assumed to be Hausdorff and to have a countable basis. The collection $\left\{\left(U_{a}, \phi_{a}\right)\right\}_{a \in A}$ is called a coordinate open cover of $M$ and $\phi_{a}$ is the trivialization of $U_{a}$. Let $u_{1}, \ldots, u_{n}$ be the standard coordinates on $\mathbf{R}^{n}$. We can write $\phi_{a}=\left(x_{1}, \ldots, x_{n}\right)$, where $x_{i}=u_{i} \circ \phi_{a}$ are a coordinate system on $U_{a}$. A function $f$ on $U_{x}$ is differentiable if $f \circ \phi_{a}^{-1}$ is a differentiable function on $\mathbb{R}^{n}$. If. $f$ is a differentiable function on $U_{a}$, the partial derivative $\partial f / \partial x_{i}$ is defined to be the $i$-th partial of the pullback function $f \circ \phi_{a}^{-1}$ on $\mathbb{R}^{\mathbf{n}}$ :

$$
\frac{\partial f}{\partial x_{i}}(p)=\frac{\partial\left(f \circ \phi_{a}^{-1}\right)}{\partial u_{i}}\left(\phi_{\alpha}(p)\right) .
$$

The tangent space to $M$ at $p$, written $T_{p} M$, is the vector space over $R$ spanned by the operators $\partial / \partial x_{1}(p), \ldots, \partial / \partial x_{n}(p)$, and a smooth vector field on $U_{a}$ is a linear combination $X_{a}=\sum f_{i} \partial / \partial x_{i}$ where the $f_{i}$ 's are smooth functions on $U_{\alpha}$. Relative to another coordinate system ( $y_{1}, \ldots, y_{n}$ ), $X_{a}=$ $\sum g_{j} \partial / \partial y_{i}$ where $\partial / \partial x_{i}$ and $\partial / \partial y_{j}$ satisfy the chain rule:

$$
\frac{\partial}{\partial x_{i}}=\sum \frac{\partial y_{j}}{\partial x_{i}} \frac{\partial}{\partial y_{j}}
$$

A $C^{\infty}$ vector field on $M$ may be viewed as a collection of vector fields $X_{a}$ on $U_{\alpha}$ which agree on the overlaps $U_{\alpha} \cap U_{\beta}$.

A differential form $\omega$ on $M$ is a collection of forms $\omega_{V}$ for $U$ in the atlas defining $\bar{M}$, which are compatible in the following sense: if $i$ and $j$ are the inclusions

then $i^{*} \omega_{U}=j^{*} \omega_{V}$ in $\Omega^{*}\left(U \cap / \mathcal{B}\right.$ By the functoriality of $\Omega^{*}$, the exterior derivative and the wedge product extend to differential forms on a manifold. Just as for $\mathbb{R}^{\boldsymbol{N}}$ a smooth map of differentiable manifolds $f: M \rightarrow N$ induces in a natural way a pullback map on forms $f^{*}: \Omega^{*}(N) \rightarrow \Omega^{*}(M)$. In this way $\Omega^{*}$ becomes a contravariant functor on the category of differentiable manifolds.

A partition of unity on a manifold $M$ is a collection of non-negative $C^{\infty}$ functions $\left\{\bar{\rho}_{a}\right\}_{\text {e }}, 1$ such that
(a) Every point has a neighborhood in which $\Sigma \rho_{\mu}$ is a finite sum.
(b) $\Sigma \rho_{a}=1$.

The basic technical tool in the theory of differentiable manifolds is the existence of a partition of unity. This result assumes two forms:
(1) Given an open cover $\left\{U_{a}\right\}_{\alpha \in I}$ of $M$, there is a partition of unity $\left\{\rho_{\alpha}\right\}_{a \in I}$ - such that the support of $\rho_{\varepsilon}$ is contained in $U_{\varepsilon}$. We say in this case that $\left\{\rho_{a}\right\}$ is a partition of unity subordinate to the open cover $\left\{U_{s}\right\}$ :
(2) Given an open cover $\left\{U_{\alpha}\right\}_{\alpha \in I}$ of $M$, there is a partition of unity $\left\{\rho_{\beta}\right\}_{\beta \in J}$ with compact support, but possibly with an index set $J$ different from $I$, such that the support of $\rho_{\beta}$ is contained in some $U_{a}$.

For a proof see Warner [1, p. 10] or de Rham [1, p. 3].
Note that in (1) the support of $\rho_{a}$ is not assumed to be compact and the index set of $\left\{\rho_{a}\right\}$ is the same as that of $\left\{U_{\alpha}\right\}$, while in (2) the reverse is true. We usually cannot demand simultaneously compact support and the same index set on a noncompact manifold $M$. For example, consider the open cover of $\mathbb{R}^{1}$ consisting of precisely one open set, namely $\boldsymbol{R}^{1}$ itself. This open cover clearly does not have a partition of unity with compact support subordinate to it.

## The Mayer-Vietoris Sequence

The Mayer-Vietoris sequence allows one to compute the cohomology of the union of two open sets. Suppose $M=U \cup V$ with $U, V$ open. Then there is a sequence of inclusions

$$
M \leftarrow U \coprod V \underset{0_{1}}{\delta_{0}} U \cap V
$$

where $U\left\lfloor V\right.$ is the disjoint union of $U$ and $V$ and $\partial_{0}$ and $\partial_{1}$ are the inclusions of $U \cap V$ in $V$ and in $U$ respectively. Applying the contravariant functor $\Omega^{*}$, we get a sequence of restrictions of forms

$$
\Omega^{*}(M) \rightarrow \Omega^{*}(U) \oplus \Omega^{*}(V) \underset{0_{1}^{*}}{\stackrel{\delta_{0}^{*}}{\rightrightarrows}} \Omega^{*}(U \cap V),
$$

where by the restriction of a form to a submanifold we mean its image under the pullback map induced by the inclusion. By taking the difference of the last two maps, we obtain the Mayer-Vietoris sequence

$$
\begin{array}{r}
0 \rightarrow \Omega^{*}(M) \rightarrow \Omega^{*}(U) \oplus \Omega^{*}(V) \rightarrow \Omega^{*}(U \cap V) \rightarrow 0  \tag{2.2}\\
(\omega, \tau) \quad \mapsto \quad \tau-\omega
\end{array}
$$

Proposition 2.3. The Mayer-Vietoris sequence is exact.

- Proof. The exactness is clear except at the last step. We first consider the case of functions on $M=R^{1}$. Let $f$ be a $C^{\infty}$ function on $U \cap V$ as shown in Figure 2.1. We must write $f$ as the difference of a function on $U$ and a function on $V$. Let $\left\{\rho_{U}, \rho_{V}\right\}$ be a partition of unity subordinate to the open cover $\{U, V\}$. Note that $\rho_{r} f$ is a function on $U$-to get a function on an open set we must multiply by the partition function of the other open set. Since.

$$
\left(\rho_{U} f\right)-\left(-\rho_{V} f\right)=f
$$

Figure 2.1
we see that $\Omega^{0}(U) \oplus \Omega^{0}(V) \rightarrow \Omega^{0}\left(R^{1}\right) \rightarrow 0$ is surjective. For a general manifold $M$, if $\omega \in \Omega^{\prime}(U \cap V)$, then $\left(-\rho_{v} \omega, \rho_{\nu} \omega\right)$ in $\Omega^{\prime}(U) \oplus \Omega^{q}(V)$ maps onto $\omega$.

The Mayer-Vietoris sequence

$$
0 \rightarrow \Omega^{*}(M) \rightarrow \Omega^{*}(U) \oplus \Omega^{*}(V) \rightarrow \Omega^{*}(U \cap V) \rightarrow 0
$$

induces a long exact sequence in cohomology, also called a Mayer-Vietoris sequence:

$$
\begin{align*}
& \left(H^{q+1}(M) \rightarrow H^{q^{+1}}(U) \oplus H^{q^{+1}}(V) \rightarrow H^{q+1}(U \cap V)^{+}\right)  \tag{2.4}\\
& d^{+}
\end{align*}
$$

We recall again the definition of the coboundary operator $d^{*}$ in this explicit instance. The short exact sequence gives rise to a diagram with exact rows

$$
\begin{aligned}
& \boldsymbol{\omega} \text { •• } \boldsymbol{\omega} \\
& \zeta \quad \omega \quad d \omega=0
\end{aligned}
$$

Let $\omega \in \Omega^{( }(U \cap V)$ be a closed form. By the exactness of the rows, there is a $\xi \in \Omega^{\mu}(U) \oplus \Omega^{\prime}(V)$ which maps to $\omega$, namely, $\xi=\left(-\rho_{v} \omega, \rho_{v} \omega\right)$. By the
commutativity of the diagram and the fact that $d \omega=0, d \xi$ goes to 0 in $\Omega^{q+1}(U \cap V)$, i.e., $-d\left(\rho_{V} \omega\right)$ and $d\left(\rho_{U} \omega\right)$ agree on the overlap $U \cap V$. Hence $d \xi$ is the image of an element in $\Omega^{\boldsymbol{q}^{+1}}(M)$. This element is easily seen to be closed and represents $d^{*}[\omega]$. As remarked earlier, it can be shown that $d^{*}[\omega]$ is independent of the choices in this construction. Explicitly we see that the coboundary operator is given by

$$
d^{*}[\omega]=\left\{\begin{array}{rll}
{\left[-d\left(\rho_{V} \omega\right)\right]} & \text { on } & U  \tag{2.5}\\
{\left[d\left(\rho_{U} \omega\right)\right]} & \text { on } & V
\end{array}\right.
$$

We define the support of a form $\omega$ on a manifold $M$ to be the smallest closed set $Z$ so that $\omega$ restricted to $Z$ is not 0 . Note that in the MayerVietoris sequence $d^{*} \omega \in H^{*}(M)$ has support in $U \cap V$.

Example 2.6 (The cohomology of the circle). Cover the circle with two open sets $U$ and $V$ as shown in Figure 2.2. The Mayer-Vietoris sequence gives

The difference map $\delta$ sends $(\omega, \tau)$ to $(\tau-\omega, \tau-\omega)$, so im $\delta$ is 1 dimensional. It follows that ker $\delta$ is also 1 -dimensional. Therefore,

$$
\begin{aligned}
& H^{0}\left(S^{1}\right)=\operatorname{ker} \delta=\mathbb{R} \\
& H^{1}\left(S^{1}\right)=\operatorname{coker} \delta=\mathbb{R}
\end{aligned}
$$

We now find an explicit representative for the generator of $H^{1}\left(S^{1}\right)$. If $\alpha \in \Omega^{0}(U \cap V)$ is a closed 0 -form which is not the image under $\delta$ of a clused form in $\Omega^{0}(U) \oplus \Omega^{0}(V)$, then $d^{*} \alpha$ will represent a generator of $H^{1}\left(S^{1}\right)$. As $\alpha$ we may take the function which is 1 on the upper piece of $U \cap V$ and 0 on

Figure 2.2

Figure 2.3
the lower piece (see Figure 2.3). Now $\alpha$ is the image of $\left(-\rho_{v} \alpha, \rho_{u} \alpha\right)$. Since $-d\left(\rho_{V} \alpha\right)$ and $d \rho_{U} \alpha$ agree on $U \cap V$, they represent a global form on $S^{1}$; this form is $d^{*} \alpha$. It is a bump 1 -form with support in $U \cap V$.

The Functor $\Omega_{c}^{*}$ and the Mayer-Vietoris Sequence for Compact Supports

Again, before taking up the Mayer-Vietoris sequence for compactly supported cohomology, we need to discuss the functorial properties of $\Omega_{c}^{*}(M)$, the algebra of forms with compact support on the manifold $M$. In general the pullback by a smooth map of a form with compact support need not
have compact support; for example, consider the pullback of functions under the projection $M \times \mathbb{R} \rightarrow M$. So $\Omega_{c}^{*}$ is not a functor on the category of manifolds and smooth maps. However if we cónsider not all smooth maps, but only an appropriate subset of smooth maps, then $\Omega_{c}^{*}$ can be made into a functor. There are two ways in which this can be done.
(a) $\Omega_{c}^{*}$ is a contravariant functor under proper maps. (A map is proper if the inverse image of every compact set is compact.)
(b) $\Omega_{c}^{*}$ is a covariant functor under inclusions of open sets.

If $j: U \rightarrow M$ is the inclusion of the open subset $U$ in the manifold $M$, then $j_{*}: \Omega_{c}^{*}(U) \rightarrow \Omega_{c}^{*}(M)$ is the map which extends a form on $U$ by zero to a form on $M$.

It is the covariant nature of $\Omega_{c}^{*}$ which we shall exploit to prove Poincaré duality for noncompact manifolds. So from now on we assume that $\Omega_{c}^{*}$ refers to the covariant functor in (b). There is also a Mayer-Vietoris sequence for this functor. As before, let $M$ be covered by two open sets $U$ and $V$. The sequence of inclusions

$$
M \leftarrow U \amalg V \leftleftarrows U \cap V
$$

gives rise to a sequence of forms with compact support

$$
\begin{gathered}
\Omega_{c}^{*}(M) \underset{\text { sum }}{\leftrightarrows_{c}} \Omega_{c}^{*}(U) \oplus \Omega_{c}^{*}(V) \underset{\substack{\text { singned } \\
\text { inclusion }}}{\delta} \Omega_{c}^{*}(U \cap V) \\
\left(-j_{*} \omega, j_{*} \omega\right) \leftarrow \quad \omega
\end{gathered}
$$

Proposition 2.7. The Mayer-Vietoris sequence of forms with compact support

$$
0 \longleftarrow \Omega_{c}^{*}(M) \longleftarrow \Omega_{c}^{*}(U) \oplus \Omega_{c}^{*}(V) \longleftarrow \Omega_{c}^{*}(U \cap V) \leftarrow 0
$$

is exact.
Proof. This time exactness is easy to check at every step. We do it for the last step. Let $\omega$ be a form in $\Omega_{c}^{*}(M)$. Then $\omega$ is the image of $\left(\rho_{U} \omega, \rho_{V} \omega\right)$ in $\Omega_{c}^{*}(U) \oplus \Omega_{c}^{*}(V)$. The form $\rho_{U} \omega$ has compact support because Supp $\rho_{U} \omega$ $\subset$ Supp $\rho_{U} \cap$ Supp $\omega$ and by a lemma from general topology, a closed subset of a compact set in a Hausdorff space is compact. This shows the surjectivity of the map $\Omega_{c}^{*}(U) \oplus \Omega_{c}^{*}(V) \rightarrow \Omega_{c}^{*}(M)$. Note that whereas in the previous Mayer-Vietoris sequence we multiply by $\rho_{V}$ to get a form on $U$, here $\rho_{U} \omega$ is a form on $U$.

Again the Mayer-Vietoris sequence gives rise to a long exact sequence in cohomology:

$$
\begin{align*}
& \widetilde{H}_{c}^{q+1}(M) \leftarrow H_{c}^{q+1}(U) \oplus H_{c}^{q+1}(V) \leftarrow H_{c}^{q+1}(U \cap V)  \tag{2.8}\\
& d_{*} \\
& H_{c}^{q}(M) \leftarrow \quad H_{c}^{q}(U) \oplus H_{c}^{q}(V) \leftarrow H_{c}^{q}(U \cap V) \square
\end{align*}
$$

Figure 2.4
Example 2.9 (The cohomology with compact support of the circle). Of course since $S^{1}$ is compact, the cohomology with compact support $H_{c}^{*}\left(S^{1}\right)$ should be the same as the ordinary de Rham cohomology $H^{*}\left(S^{1}\right)$. Nonetheless, as an illustration we will compute $\boldsymbol{H}_{c}^{*}\left(S^{\mathbf{1}}\right)$ from the Mayer-Vietoris sequence for compact supports:

Here the map $\delta$ sends $\omega=\left(\omega_{1}, \omega_{2}\right) \in H_{c}^{1}(U \cap V)$ to $\left(-\left(j_{U}\right)_{\psi} \omega,\left(j_{V}\right)_{q} \omega\right) \in$ $H_{c}^{1}(U) \oplus H_{c}^{1}(V)$, where $j_{u}$ and $j_{V}$ are the inclusions of $U \cap V$ in $U$ and in $V$ respectively. Since im $\delta$ is 1 -dimensional,

$$
\begin{aligned}
& H_{c}^{0}\left(S^{1}\right)=\operatorname{ker} \delta=\mathbf{R} \\
& H_{c}^{1}\left(S^{1}\right)=\text { coker } \delta=\mathbf{R} .
\end{aligned}
$$

## §3 Orientation and Integration

Orientation and the Integral of a Differential Form
Let $x_{1}, \ldots, x_{n}$ be the standard coordinates on $\mathbf{R}^{n}$. Recall that the Riemann integral of a differentiable function $f$ with compact support is

$$
\int_{R^{+}} f\left|d x_{1} \ldots d x_{n}\right|=\lim _{\Delta x_{1} \rightarrow \theta} \sum f \Delta x_{1} \ldots \Delta x_{n} .
$$

We define the integral of an $n$-form with compact support $\omega=f d x_{1} \ldots d x_{n}$ to be the Riemann integral $\int_{R^{-}} f\left|d x_{1} \ldots d x_{n}\right|$. Note that contraty to the usual calculus notation we put an absolute value sign in the Riemann
integral; this is to emphasize the distinction between the Riemann integral of a function and the integral of a differential form. While the order of $x_{1}, \ldots, x_{n}$ matters in a differential form, it does not in a Riemann integral; if $\pi$ is a permutation of $\{1, \ldots, n\}$, then

$$
\int f d x_{\pi(1)} \ldots d x_{\pi(n)}=(\operatorname{sgn} \pi) \cdot \int f\left|d x_{1} \ldots d x_{n}\right|
$$

but

$$
\int f\left|d x_{\pi(1)} \ldots d x_{\pi(n)}\right|=\int f\left|d x_{1} \ldots d x_{n}\right|
$$

In a situation where there is no possibility of confusion, we may revert to the usual calculus notation.

So defined, the integral of an $n$-form on $\mathbb{R}^{\mathbf{1}}$ depends on the coordinates $x_{1}, \ldots, x_{n}$. From our point of view a change of coordinates is given by a diffeomorphism $T: \mathbf{R}^{n} \rightarrow \mathbf{R}^{n}$ with coordinates $y_{1}, \ldots, y_{n}$ and $x_{1}, \ldots, x_{n}$ respectively:

$$
x_{i}=x_{i} \circ T\left(y_{1}, \ldots, y_{n}\right)=T\left(y_{1}, \ldots, y_{n}\right)
$$

We now study how the integral $\int \omega$ transforms under such diffeomorphisms.

Exercise 3.1. Show that $d T_{1} \ldots d T_{n}=J(T) d y_{1} \ldots d y_{n}$, where $J(T)=$ $\operatorname{det}\left(\partial x_{i} / \partial y_{j}\right)$ is the Jacobian determinant of $T$.

Hence,

$$
\int_{\mathbb{R}^{0}} T^{*} \omega=\int_{\mathbb{R}^{*}}(f \circ T) d T_{1} \ldots d T_{n}=\int_{\mathbb{R}^{0}}(f \circ T) J(T) d y_{1} \ldots d y_{n}
$$

relative to the coordinate system $y_{1}, \ldots, y_{n}$. On the other hand, by the change of variables formula,

$$
\int_{R^{*}} \omega=\int_{R^{+}} f\left(x_{1}, \ldots, x_{n}\right) d x_{1} \ldots d x_{n}=\int_{R^{+}}(f \circ T)|J(T)| d y_{1} \ldots d y_{n}
$$

Thus

$$
\int_{\mathbb{R}^{*}}^{-\stackrel{~}{*}} T^{*} \omega= \pm \int_{R^{*}} \omega
$$

depending on whether the Jacobian determinant is positive or negative. In general if $T$ is a diffeomorphism of open subsets of $\mathbb{R}^{n}$ and if the Jacobian determinant $J(T)$ is everywhere positive, then $T$ is said to be orientationpreserving. The integral on $R^{n}$ is not invariant under the whole group of
diffeomorphisms of $\mathbb{R}^{n}$, but only under the subgroup of orientationpreserving diffeomorphisms.

Let $M$ be a differentiable manifold with atlas $\left\{\left(U_{\alpha}, \phi_{\alpha}\right)\right\}$. We say that the atlas is oriented if all the transition functions $g_{a \beta}=\phi_{a} \circ \phi_{\beta}^{-1}$ are orientation-preserving, and that the manifold is orientable if it has an oriented atlas.

Proposition 3.2. A manifold $M$ of dimension $n$ is orientable if and only if it has a global nowhere vanishing $n$-form.

Proof. Observe that $T: \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$ is orientation-preserving if and only if $T^{*} d x_{1} \ldots d x_{n}$ is a positive multiple of $d x_{1} \ldots d x_{n}$ at every point.
$(\Leftrightarrow)$ Suppose $M$ has a global nowhere-vanishing $n$-form $\omega$. Let $\phi_{a}: U_{\alpha} \leadsto$ $\mathbb{R}^{n}$ be a coordinate map. Then $\phi_{a}^{*} d x_{1} \ldots d x_{n}=f_{a} \omega$ where $f_{a}$ is a nowherevanishing real-valued function on $U_{d}$. Thus $f_{a}$ is either everywhere positive or everywhere negative. In the latter case interchange $x_{1}$ and $x_{2}$. Since $\phi_{\alpha}^{*} d x_{2} d x_{1} d x_{3} \ldots d x_{n}=-\phi_{\alpha}^{*} d x_{1} d x_{2} d x_{3} \ldots d x_{n}=\left(-f_{\alpha}\right) \omega$, we may assume $f_{a}$ to be positive for all $\alpha$. Hence, any transition function $\phi_{\beta} \phi_{a}^{-1}: \boldsymbol{R}^{*}$ $\rightarrow \mathbb{R}^{n}$ will pull $d x_{1} \ldots d x_{n}$ to a positive multiple of itself. So $\left\{\left(U_{a}, \phi_{a}\right)\right\}$ is an oriented atlas.
$(\Rightarrow)$ Conversely, suppose $M$ has an oriented atlas $\left\{\left(U_{\varepsilon}, \phi_{\alpha}\right)\right\}$. Then

$$
\left(\phi_{\beta} \phi_{a}^{-1}\right)^{*}\left(d x_{1} \ldots d x_{n}\right)=\lambda d x_{1} \ldots d x_{n}
$$

for some positive function $\lambda$. Thus

$$
\phi_{\#}^{*} d x_{1} \ldots d x_{n}=\left(\phi_{\alpha}^{*} \lambda\right)\left(\phi_{a}^{*} d x_{1} \ldots d x_{n}\right) .
$$

Denoting $\phi_{a}^{*} d x_{1} \ldots d x_{n}$ by $\omega_{a}$, we see that $\omega_{g}=f \omega_{a}$ where $f=\phi_{k}^{*} \lambda=\lambda \circ$ $\phi_{\alpha}$ is a positive function on $U_{a} \cap U_{B}$.

Let $\omega=\sum \rho_{\alpha} \omega_{a}$ where $\rho_{\alpha}$ is a partition of unity subordinate to the open cover $\left\{U_{a}\right\}$. At each point $p$ in $M$, all the forms $\omega_{a}$, if defined, are positive multiples of one another. Since $\rho_{a} \geq 0$ and not all $\rho_{a}$ can vanish at a point, $\omega$ is nowhere vanishing.

Any two global nowhere vanishing $n$-forms $\omega$ and $\omega^{\prime}$ on an orientable manifold $M$ of dimension $n$ differ by a nowhere vanishing function: $\omega=f \omega^{\prime}$. If $M$ is connected, then $f$ is either everywhere positive or everywhere negative. We say that $\omega$ and $\omega^{\prime}$ are equivalent if $f$ is positive. Thus on a connected orientable manifold $M$ the nowhere vanishing $n$-forms fall into two equivalence classes. Either class is called an orientation on $M$, written [M]. For example, the standard orientation on $\bar{R}^{n}$ is given by $d x_{1} \ldots d x_{n}$.

Now choose an orientation [M] on $M$. Given a top form $\tau$ in $\Omega_{e}^{\mu}(M)$, we define its integral by

$$
\int_{(M)} \tau=\sum_{\alpha} \int_{U_{a}} \rho_{\varepsilon} \tau
$$

where $\int_{\nu_{\alpha}} \rho_{\alpha} \tau$ means $\int_{\mathbb{R}_{k}}\left(\phi_{\alpha}^{-1}\right)^{*}\left(\rho_{\alpha} \tau\right)$ for some orientation-preserving trivialization $\phi_{a}: U_{\alpha} \rightarrow \mathbb{R}^{n}$; as in Proposition 2.7, $\rho_{\alpha} \tau$ has compact support. By the orientability assumption, the integral over a coordinate patch $\int_{U_{a}} \omega$ is well defined. With a fixed orientation on $M$ understood, we will often write $\int_{M} \tau$ instead of $\int_{[M]} \tau$. Reversing the orientation results in the negative of the integral.

Proposition 3.3. The definition of the integral $\int_{M} \tau$ is independent of the oriented ailas $\left\{\left(U_{\alpha}, \phi_{\alpha}\right)\right\}$ and the partition of unity $\left\{\rho_{\alpha}\right\}$.
Proof. Let $\left\{V_{\beta}\right\}$ be another oriented atlas of $M$, and $\left\{\chi_{\beta}\right\}$ a partition of unity subordinate to $\left\{V_{\beta}\right\}$. Since $\sum_{\beta} \chi_{\beta}=1$,

$$
\sum_{a} \int_{U_{\alpha}} \rho_{\alpha} \tau=\sum_{\alpha, \beta} \int_{U_{z}} \rho_{\alpha} \chi_{\beta} \tau
$$

Now $\rho_{a} \chi_{\beta} \tau$ has support in $U_{g} \cap V_{\beta}$, so

$$
\int_{U_{a}} \rho_{a} x_{\beta} \tau=\int_{V_{g}} \rho_{a} x_{\beta} \tau .
$$

Therefore

$$
\sum_{a} \int_{U_{a}} \rho_{a} \tau=\sum_{a, \beta} \int_{V_{b}} \rho_{a} x_{\beta} \tau=\sum_{\beta} \int_{V_{\beta}} \chi_{\beta} \tau .
$$

A manifold $M$ of dimension $n$ with boundary is given by an atlas $\left\{\left(U_{a}, \phi_{a}\right)\right\}$ where $U_{a}$ is homeomorphic to either $\mathbb{R}^{n}$ or the upper half space $1 . H^{n}=\left\{\left(x_{1}, \ldots, x_{n}\right) \mid x_{n} \geq 0\right\}$. The boundary $\partial M$. of $M$ is an $(n-1)-$ dimensional manifold. An oriented atlas for $M$ induces in a natural way an oriented atlas for $\partial M$. This is a consequence of the following lemma.

Lemma 3.4. Let $T: H^{n} \rightarrow H^{n}$ be a diffeomorphism of the upper half space with everywhere positive Jacobian determinant. $T$ induces a map $\bar{T}$ of the boundary of $\mathrm{H}^{n}$ to itself. The induced map $\bar{T}$, as a diffeomorphism of $\mathbb{R}^{n-1}$, also has positive Jacobian determinant everywhere.

Proof. By the inverse function theorem an interior point of $H^{n}$ must be the image of an interior point. Hence $T$ maps the boundary to the boundary. We will check that $\bar{T}$ has positive Jacobian determinant for $n=2$; the general case is similar.

Let $T$ be given by

$$
\begin{aligned}
& x_{1}=T_{1}\left(y_{1}, y_{2}\right) \\
& x_{2}=T_{2}\left(y_{1}, y_{2}\right)
\end{aligned}
$$

Then $\bar{T}$ is given by

$$
x_{1}=T_{1}\left(y_{1}, 0\right)
$$

Figure 3.1
By assumption

$$
\left|\begin{array}{ll}
\frac{\partial T_{1}}{\partial y_{1}}\left(y_{1}, 0\right) & \frac{\partial T_{2}}{\partial y_{2}}\left(y_{1}, 0\right) \\
\frac{\partial T_{2}}{\partial y_{1}}\left(y_{1}, 0\right) & \frac{\partial T_{2}}{\partial y_{2}}\left(y_{1}, 0\right)
\end{array}\right|>0
$$

Since $0=T_{2}\left(y_{1}, 0\right)$ for all $y_{1}, \partial T_{2} / \partial y_{1}\left(y_{1}, 0\right)=0$; since $T$ maps the upper half plane to itself,

$$
\frac{\partial T_{2}}{\partial y_{2}}\left(y_{1}, 0\right)>0
$$

Therefore

$$
\frac{\partial T_{1}}{\partial y_{1}}\left(y_{1}, 0\right)>0
$$

Let the upper half space $\mathscr{H}^{n}=\left\{x_{n} \geq 0\right\}$ in $\mathbb{R}^{n}$ be given the standard orientation $d x_{1} \ldots d x_{n}$. Then the induced orientation on its boundary $\partial \mathrm{H}^{n}=\left\{x_{n}=0\right\}$ is by definition the equivalence class of $(-1)^{n} d x_{1} \ldots d x_{n-1}$; this sign is needed to make Stokes' theorem sign-free. In general for $M$ an oriented manifold with boundary, we define the induced orientation [ $\partial \mathrm{M}$ ] on $\partial M$ by the following requirement: if $\phi$ is an orientation-preserving diffeomorphism of some open set $U$ in $M$ into the upper half space $H^{\prime \prime}$, then

$$
\phi^{*}\left[\partial H^{n}\right]=\left.[\partial M]\right|_{00},
$$

where $\partial U=(\partial M) \cap U$ (see Figure 3.1).

## Stokes' Theorem

A basic result in the theory of integration is
Theorem 3.5 (Stokes' Theorem). If $\omega$ is an ( $n-1$ )-form with compact support on an oriented manifold $M$ of dimension $n$ and if $\partial M$ is given the induced
orientation, then

$$
\int_{M} d \omega=\int_{O M} \omega
$$

We first examine two special cases.
Spectal Case $1\left(\mathbb{R}^{n}\right)$. By the linearity of the integrand we may take $\omega$ to be $f d x_{1} \ldots d x_{n-1}$. Then $d \omega= \pm \partial f / \partial x_{n} d x_{1} \ldots d x_{n}$. By Fubini's theorem,

$$
\int_{\mathbb{R}^{\prime}} d \omega= \pm \int\left(\int_{-\infty}^{\infty} \cdot \frac{\partial f}{\partial x_{n}} d x_{n}\right) d x_{1} \ldots d x_{n-1}
$$

But $\int_{-\infty}^{\infty} \partial f / \partial x_{n} d x_{n}=f\left(x_{1}, \ldots, x_{n-1}, \infty\right)-f\left(x_{1}, \ldots, x_{n-1},-\infty\right)=0$ because $f$ has compact support. Since $\mathbb{R}^{n}$ has no boundary, this proves Stokes' theorem for $\mathbb{R}^{n}$.

Special Case 2 (The upper half plane). In this case (see Figure 3.2)

$$
\omega .=f(x, y) d x+g(x, y) d y
$$

and

$$
d \omega=\left(-\frac{\partial f}{\partial y}+\frac{\partial g}{\partial x}\right) d x d y
$$

Note that

$$
\int_{H^{2}} \frac{\partial g}{\partial x} d x d y=\int_{0}^{\infty}\left(\int_{-\infty}^{\infty} \frac{\partial g}{\partial x} d x\right) d y=\int g(\infty, y)-g(-\infty, y) d y=0
$$

since $g$ has compact support. Therefore,

$$
\begin{aligned}
\int_{H^{2}} \omega & =-\int_{H^{2}} \frac{\partial f}{\partial y} d x d y=-\int_{-\infty}^{\infty}\left(\int_{0}^{\infty} \frac{\partial f}{\partial y} d y\right) d x \\
& =-\int_{-\infty}^{\infty}(f(x, \infty)-f(x, 0)) d x \\
& =\int_{-\infty}^{\infty} f(x, 0) d x=\int_{O H^{2}} \omega
\end{aligned}
$$

Figure 3.2
where the last equality holds because the restriction of $g(x, y) d y$ to $\partial H^{2}$ is 0 . So Stokes' theorem holds for the upper half plane.

The case of the upper half space in $\mathbb{R}^{n}$ is entirely analogous.
Exercise 3.6. Prove Stokes' theorem for the upper half space.
We now consider the general case of a manifold of dimension $n$. Let $\left\{U_{a}\right\}$ be an oriented atlas for $M$ and $\left\{\rho_{a}\right\}$ a partition of unity subordinate to $\left\{U_{a}\right\}$. Write $\omega=\sum \rho_{a} \omega$. Since Stokes' theorem $\int_{M} d \omega=\int_{\partial M} \omega$ is linear in $\omega$, we need to prove it only for $\rho_{a} \omega$, which bas the virtue that its support is contained entirely in $U_{a}$. Furthermore, $\rho_{a} \omega$ has compact support because

$$
\text { Supp } \rho_{\alpha} \omega \subset \operatorname{Supp} \rho_{\alpha} \cap \operatorname{Supp} \omega
$$

is a closed subset of a compact set. Since $U_{\alpha}$ is diffeomorphic to either $\mathbb{R}^{n}$ or the upper half space $\mathbb{H}^{n}$, by the computations above Stokes' theorem holds for $U_{a}$. Consequently

$$
\int_{M} d \rho_{\alpha} \omega=\int_{U_{a}} d \rho_{\alpha} \omega=\int_{\partial U_{\alpha}} \rho_{\alpha} \omega=\int_{\partial M} \rho_{\alpha} \omega
$$

This concludes the proof of Stokes' theorem in general.

## §4 Poincaré Lemmas

## The Poincaré Lemma for de Rham Cohomology

In this section we compute the ordinary cohomology and the compactly supported cohomology of $\mathbb{R}^{n}$. Let $\pi: \mathbb{R}^{n} \times \mathbb{R}^{1} \rightarrow \mathbb{R}^{n}$ be the projection on the first factor and $s: \mathbb{R}^{n} \rightarrow \mathbb{R}^{n} \times \mathbb{R}^{1}$ the zero section.

$$
\begin{aligned}
& \pi(x, t)=x \\
& s(x)=(x, 0)
\end{aligned}
$$

We will show that these maps induce inverse isomorphisms in cohomology and therefore $H^{*}\left(\mathbb{R}^{n+1}\right) \simeq H^{*}\left(\mathbb{R}^{n}\right)$. As a matter of convention all maps are assumed to be $C^{\infty}$ unless otherwise specified.

Since $\pi \circ s=1$, we have trivially $s^{*} \circ \pi^{*}=1$. However $s \circ \pi \neq 1$ and correspondingly $\pi^{*} \circ s^{*} \neq 1$ on the level of forms. For example, $\pi^{*} \circ s^{*}$ sends the function $f(x, t)$ to $f(x, 0)$, a function which is constant along every. fiber. To show that $\pi^{*} \circ s^{*}$ is the identity in cohomology, it is enough to find a map $K$ on $\Omega^{*}\left(\mathbb{R}^{n} \times \mathbb{R}^{1}\right)$ such that

$$
1-\pi^{*} \circ s^{*}= \pm(d K \pm K d)
$$

for $d K \pm K d$ maps closed forms to exact forms and therefore induces zero in cohomology. Such a $K$ is called a homotopy operator; if it exists, we say that $\pi^{*} \circ s^{*}$ is chain homoropic to the identity. Note that the homotopy operator $K$ decreases the degree by 1 .

Every form on $\mathbb{R}^{n} \times \mathbb{R}$ is uniquely a linear combination of the following two types of forms:

$$
\begin{aligned}
& \text { (I) }\left(\pi^{*} \phi\right) f(x, t) \\
& \text { (II) }\left(\pi^{*} \phi\right) f(x, t) d t
\end{aligned}
$$

where $\phi$ is a form on the base $\mathbb{R}^{n}$. We define $K: \Omega^{q}\left(\mathbb{R}^{n} \times \mathbb{R}\right) \rightarrow$ $\Omega^{q-1}\left(\mathbb{R}^{n} \times \mathbb{R}\right)$ by

$$
\text { (I) }\left(\pi^{*} \phi\right) f(x, t) \mapsto 0,
$$

(II) $\left(\pi^{*} \phi\right) f(x, t) d t \mapsto\left(\pi^{*} \phi\right) \int_{0}^{t} f$.

Let's check that $K$ is indeed a homotopy operator. We will use the simplified notation $\partial f / \partial x d x$ for $\sum \partial f / \partial x_{i} d x_{1}$, and $\int g$ for $\int g(x, t) d t$. On forms of type (I),

$$
\begin{aligned}
\omega & =\left(\pi^{*} \phi\right) \cdot f(x, t), \quad \operatorname{deg} \omega=q \\
\left(1-\pi^{*} s^{*}\right) \omega & =\left(\pi^{*} \phi\right) \cdot f(x, t)-\pi^{*} \phi \cdot f(x, 0) \\
(d K-K d) \omega & =-K d \omega=-K\left(\left(d \pi^{*} \phi\right) f+(-1)^{q} \pi^{*} \phi\left(\frac{\partial f}{\partial x} d x+\frac{\partial f}{\partial t} d t\right)\right) \\
& =(-1)^{q-1} \pi^{*} \phi \int_{0}^{t} \frac{\partial f}{\partial t}=(-1)^{q-1} \pi^{*} \phi[f(x, t)-f(x, 0)] .
\end{aligned}
$$

Thus,

$$
1-\pi^{*} s^{*}=(-1)^{q-1}(d K-K d)
$$

On forms of type (II),

$$
\begin{aligned}
\omega & =\left(\pi^{*} \phi\right) f d t, \quad \operatorname{deg} \omega=q, \\
d \omega & =\left(\pi^{*} d \phi\right) f d t+(-1)^{q-1}\left(\pi^{*} \phi\right) \frac{\partial f}{\partial x} d x d t . \\
\left(1-\pi^{*} s^{*}\right) \omega & =\omega \text { because } s^{*}(d t)=d\left(s^{*} t\right)=d(0)=0 . \\
K d \omega & =\left(\pi^{*} d \phi\right) \int_{0}^{t} f+(-1)^{q-1}\left(\pi^{*} \phi\right) d x \int_{0}^{t} \frac{\partial f}{\partial x}, \\
d K \omega & =\left(\pi^{*} d \phi\right) \int_{0}^{t} f+(-1)^{q-1}\left(\pi^{*} \phi\right)\left[d x\left(\int_{0}^{t} \frac{\partial f}{\partial x}\right)+f d t\right] .
\end{aligned}
$$

Thus

$$
(d K-K d) \omega=(-1)^{p^{-1}} \omega .
$$

In either case,

$$
1-\pi^{*} \circ s^{*}=(-1)^{-1}(d K-K d) \quad \text { on } \quad \Omega^{a}\left(\mathbb{R}^{n} \times \mathbf{R}\right)
$$

This proves

Proposition 4.1. The maps $H^{*}\left(\mathbb{R}^{n} \times \mathbb{R}^{1}\right) \underset{s^{*}}{\kappa^{*}} H^{*}\left(\mathbb{R}^{n}\right)$ are isomorphisms.
By induction, we obtain the cohomology of $\mathbb{R}^{n}$.

## Corollary 4.1.1 (Poincaré Lemma).

$$
H^{*}\left(\mathbb{R}^{n}\right)=H^{*}(\text { point })= \begin{cases}\mathbb{R} & \text { in dimension } 0 \\ 0 & \text { elsewhere }\end{cases}
$$

Consider more generally

If $\left\{U_{a}\right\}$ is an atlas for $M$, then $\left\{U_{a} \times R^{1}\right\}$ is an atlas for $M \times \mathbf{R}^{1}$. Again every form on $M \times \mathbb{R}^{1}$ is a linear combination of the two types of forms (I) and (II). We can define the homotopy operator $K$ as before and the proof carries over word for word to show that $H^{*}\left(M \times R^{1}\right) \simeq H^{*}(M)$ is an isomorphism via $\pi^{*}$ and $s^{*}$.

Corollary 4.1.2 (Homotopy Axiom for de Rham Cohomology). Homotopic maps induce the same map in cohomology.
Proof. Recall that a homotopy between two maps $f$ and $g$ from $M$ to $N$ is a $\operatorname{map} F: M \times \boldsymbol{R}^{1} \rightarrow N$ such that

$$
\left\{\begin{array}{l}
F(x, t)=f(x) \text { for } t \geq 1 \\
F(x, t)=g(x) . \text { for } t \leq 0
\end{array}\right.
$$

Equivalently if $s_{0}$ and $s_{1}: M \rightarrow M \times \boldsymbol{R}^{1}$ are the 0 -section and 1 -section respectively, i.e., $s_{1}(x)=(x, 1)$, then

$$
\begin{aligned}
& f=F \circ s_{1} \\
& g=F \circ s_{0}
\end{aligned}
$$

Thus

$$
\begin{aligned}
& f^{*}=\left(F \circ s_{1}\right)^{*}=s_{i}^{*} \circ F^{*}, \\
& g^{*}=\left(F \circ s_{0}\right)^{*}=s_{0}^{*} \circ F^{*} .
\end{aligned}
$$

Since $s_{1}^{*}$ and $s^{*}$ both invert $\pi^{*}$, they are equal. Hence,

$$
f^{*}=\theta^{*}
$$

Two manifolds $M$ and $N$ are said to have the same homotopy type in the $C^{\infty}$ sense if there are $C^{\infty}$ maps $f: M \rightarrow N$ and $g: N \rightarrow M$ such that $g \circ f$ and $f \circ g$ are $C^{\infty}$ homotopic to the identity on $M$ and $N$ respectively.* A manifold having the homotopy type of a point is said to be contractible.

Corollary 4.1.2.1. Two manifolds with the same homotopy type have the same de Rham cohomology.

If $i: A \subset M$ is the inclusion and $r: M \rightarrow A$ is a map which restricts to the identity on $A$, then $r$ is called a retraction of $M$ onto $A$. Equivalently, $r \circ i: A \rightarrow A$ is the identity. If in addition $i \circ r: M \rightarrow M$ is homotopic to the identity on $M$, then $r$ is said to be deformation retraction of $M$ onto $A$. In this case $A$ and $M$ have the same homotopy type.

Corollary 4.1.2.2. If $A$ is a deformation retract of $M$, then $A$ and $M$ have the same de Rham cohomology.

Exercise 4.2. Show that $r: \mathbb{R}^{2}-\{0\} \rightarrow S^{1}$ given by $r(x)=x /\|x\|$ is a deformation retraction.
' Exercise 4.3. The cohomology of the $n$-sphere $S^{n}$. Cover $S^{n}$ by two open sets $U$ and $V$ where $U$ is slightly larger than the northern hemisphere and $V$ slightly larger than the southern hemisphere (Figure 4.1). Then $U \cap V$ is diffeomorphic to $S^{n-1} \times \mathbb{R}^{2}$ where $S^{n-1}$ is the equator. Using the MayerVietoris sequence, show that

$$
H^{*}\left(S^{n}\right)= \begin{cases}\mathbb{R} & \text { in dimensions } 0, n \\ 0 & \text { otherwise } .\end{cases}
$$

We saw previously that a generator of $H^{1}\left(S^{1}\right)$ is a bump 1 -form on $S^{1}$ which gives the isomorphism $H^{1}\left(S^{1}\right) \simeq \mathbb{R}^{1}$ under integration (see Figure

Figure 4.1

[^0]

Figure 4.2
4.2). This bump 1 -form propagates by the boundary map of the MayerVietoris sequence to a bump 2 -form on $S^{2}$, which represents a generator of $H^{2}\left(S^{2}\right)$. In general a generator of $H^{n}\left(S^{n}\right)$ can be taken to be a bump $n$-form on $S^{n}$.

Exercise 4.3.I Volume form on a sphere. Let $S^{n}(r)$ be the sphere of radius $r$

$$
x_{1}^{2}+\cdots+x_{n+1}^{2}=r^{2}
$$

in $\mathbb{R}^{n+1}$, and let

$$
\omega=\frac{1}{r} \sum_{i=1}^{n+1}(-1)^{i-1} x_{i} d x_{1} \cdots \dot{d x_{i}} \cdots d x_{n+1}
$$

(a) Write $S^{n}$ for the unit sphere $S^{n}(1)$. Compute the integral $\int_{5} \omega$ and conclude that $\omega$ is not exact.
(b) Regarding $r$ as a function on $R^{n+1}-0$, show that $(d r) \cdot u=d x_{1} \cdots$ $d x_{n+1}$. Thus $\omega$ is the Euclidean yolume form on the sphere $S^{n}(r)$.

From (a) we obtain an explicit formula for the generator of the top cohomology of $S^{n}$ (although not as a bump form). For example, the generator of $H^{2}\left(S^{2}\right)$ is represented by

$$
\sigma=\frac{1}{4 \pi}\left(x_{1} d x_{2} d x_{3}-x_{2} d x_{1} d x_{3}+x_{3} d x_{1} d x_{2}\right)
$$

## The Poincaré Lemma fờ.Compactly Supported Cohomology

The computation of the compactly supported cohomology $H_{e}^{*}\left(R^{\prime \prime}\right)$ is again by induction; we will show that there is an isomorphism

$$
H_{c}^{*+1}\left(\mathbb{R}^{n} \times \mathbf{R}^{1}\right) \simeq H_{c}^{*}\left(\mathbf{R}^{n}\right)
$$

Note that here, unlike the previous case, the dimension is shifted by one.
More generally consider the projection $\pi: M \times \mathbf{R}^{1} \rightarrow M$. Since the pullback of a form on $M$ to a form on $M \times R^{1}$ necessarily has noncompact support, the pullback map $\pi^{*}$ does not send $\Omega_{c}^{*}(M)$ to $\Omega_{c}^{*}\left(M \times \mathbf{R}^{1}\right)$. However, there is a push-forward map $\pi_{\text {为 }}: \Omega_{c}^{*}\left(M \times \mathbf{R}^{1}\right) \rightarrow \Omega_{*}^{*-1}(M)$, called integration along the fiber, defined as follows. First note that a compactly
supported form on $M \times \mathbb{R}^{1}$ is a linear combination of two types of forms:

$$
\begin{aligned}
& \text { (I) } \pi^{*} \phi \cdot f(x, t), \\
& \text { (II) } \pi^{*} \phi \cdot f(x, t) d t,
\end{aligned}
$$

where $\phi$ is a form on the base (not necessarily with compact support), and $f(x, t)$ is a function with compact support. We define $\pi_{*}$ by

$$
\begin{align*}
& \text { (I) } \pi^{*} \phi \cdot f(x, t) \mapsto 0 \\
& \text { (II) } \pi^{*} \phi \cdot f(x, t) d t \mapsto \phi \int_{-\infty}^{\infty} f(x, t) d t \tag{4.4}
\end{align*}
$$

Exercise 4.5. Show that $d \pi_{*}=\pi_{*} d$; in other words, $\pi_{*}: \Omega_{c}^{*}\left(M \times \mathbb{R}^{1}\right) \rightarrow$ $\Omega_{c}^{*-1}(M)$ is a chain map.

By this exercise $\pi_{*}$ induces a map in cohomology $\pi_{*}: H_{c}^{*} \rightarrow H_{c}^{*-1}$. To produce a map in the reverse direction, let $e=e(t) d t$ be a compactly supported 1 -form on $\mathbf{R}^{1}$ with total integral 1 and define
by

$$
e_{*}: \Omega_{c}^{*}(M) \rightarrow \Omega_{c}^{*+1}\left(M \times \mathbb{R}^{1}\right)
$$

$$
\phi \mapsto \phi \wedge e
$$

The map $e_{*}$ clearly commutes with $d$, so it also induces a map in cohomology. It follows directly from the definition that $\pi_{*}{ }^{\circ} e_{*}=1$ on $\Omega_{*}^{*}\left(\mathbb{R}^{n}\right)$. Although $e_{*} \circ \pi_{*} \neq 1$ on the level of forms, we shall produce a homotopy operator $K$ between 1 and $e_{*} \circ \pi_{*}$; it will then follow that $e_{*} \circ \pi_{*}=1$ in cohomology.

To streamline the notation, write $\phi \cdot f$ for $\pi^{*} \phi \cdot f(x, t)$ and $\int f$ for $\int f(x, t) d t$. The homotopy operator $K: \Omega_{c}^{*}\left(M \times \boldsymbol{R}^{1}\right) \rightarrow \Omega_{c}^{*-1}\left(M \times \mathbf{R}^{1}\right)$ is defined by
(I) $\phi \cdot f \mapsto 0$,
(II) $\phi \cdot f d t \mapsto \phi \int_{-\infty}^{t} f-\phi A(t) \int_{-\infty}^{\infty} f \quad$ where $A(t)=\int_{-\infty}^{t} e$.

Proposition 4.6. $1^{\text {² }}-e_{*} \pi_{*}=(-1)^{q-1}(d K \leq K d)$ on $H_{c}^{q}\left(M \times R^{1}\right)$.
Proof. On forms of type (I), assuming deg $\phi=q$, we have
$\left(1-e_{*} \pi_{*}\right) \phi \cdot f=\phi \cdot f$,

$$
\begin{aligned}
(d K-K d) \phi \cdot f & =-K\left(d \phi \cdot f+(-1)^{q} \phi \frac{\partial f}{\partial x} d x+(-1)^{q} \phi \frac{\partial f}{\partial t} d t\right) \\
& =(-1)^{4-1}\left(\phi \int_{-\infty}^{t} \frac{\partial f}{\partial t}-\phi A(t) \int_{-\infty}^{\infty} \frac{\partial f}{\partial t}\right) \cdots \\
& =(-1)^{-1} \phi f . \quad\left[\text { Here } \int_{-\infty}^{\infty} \frac{\partial f}{\partial t}=f(x, \infty)-f(x,-\infty)=0 .\right]
\end{aligned}
$$

- 

So

$$
1-e_{*} \pi_{*}=(-1)^{q-1}(d K-K d) .
$$

On forms of type (II), now assuming deg $\phi=q-1$, we have

$$
\begin{aligned}
\left(1-e_{*} \pi_{*}\right) \phi f d t= & \phi f d t-\phi\left(\int_{-\infty}^{\infty} f\right) \wedge e \\
(d K)(\phi f d t)= & (d \phi) \int_{-\infty}^{t} f+(-1)^{q-1} \phi \int_{-\infty}^{t} \frac{\partial f}{\partial x} d x d t+(-1)^{q-1} \phi f d t \\
& -(d \phi) A(t) \int_{-\infty}^{\infty} f-(-1)^{q-1} \phi\left[e \int_{-\infty}^{\infty} f+A(t)\left(\int_{-\infty}^{\infty} \frac{\partial f}{\partial x}\right) d x\right] \\
(K d)(\phi f d t)= & K\left((d \phi) \cdot f d t+(-1)^{q-1} \phi \frac{\partial f}{\partial x} d x d t\right) \\
= & (d \phi) \int_{-\infty}^{t} f-(d \phi) A(t) \int_{-\infty}^{\infty} f \\
& +(-1)^{q-1}\left[\phi \int_{-\infty}^{t} \frac{\partial f}{\partial x} d x d t-\phi A(t)\left(\int_{-\infty}^{\infty} \frac{\partial f}{\partial x}\right) d x\right] .
\end{aligned}
$$

So

$$
(d K-K d) \phi f d t=(-1)^{q-1}\left[\phi f d t-\phi\left(\int_{-\infty}^{\infty} \cdot f\right) e\right]
$$

and the formula again holds.

This concludes the proof of the following
Proposition 4.7. The maps

$$
H_{c}^{*}\left(M \times R^{1}\right) \stackrel{x_{\theta}}{\underset{x_{*}}{\rightleftarrows}} H_{c}^{*-1}(M)
$$

are isomorphisms.
Corollary 4.7.1 (Poincaré Lemma for Compact Supports).

$$
H_{c}^{*}\left(\mathbb{R}^{n}\right)= \begin{cases}\mathbb{R} & \text { in dimension } n \\ 0 & \text { otherwise }\end{cases}
$$

Here the isomorphism $H_{c}^{n}\left(\mathbb{R}^{n}\right) \leadsto \mathbb{R}$ is given by iterated $\pi_{*}$, i.c., by intogration over $\mathbb{R}^{\prime \prime}$.

To determine a generator for $H_{c}^{n}\left(\mathbb{R}^{n}\right)$, we start with the constant function 1 on a point and iterate with $e_{*}$. This gives $e\left(x_{1}\right) d x_{1} e\left(x_{2}\right) d x_{2} \ldots e\left(x_{n}\right) d x_{n}$.

So a generator for $H_{c}^{n}\left(\mathbb{R}^{n}\right)$ is a bump $n$-form $\alpha(x) d x_{1} \ldots d x_{n}$ with

$$
\int_{R^{C}} \alpha(x) d x_{1} \ldots d x_{n}=1
$$

The support of $\alpha$ can be made as small as we like.
Remark. This Poincaré lemma shows that the compactly supported cohomology is not invariant under homotopy equivalence, although it is of course invariant under diffeomorphisms.

Exercise 4.8. Compute the cohomology groups $H^{*}(M)$ and $H_{c}^{*}(M)$ of the open Möbius strip $M$, i.e., the Möbius strip without the bounding edge (Figure 4.3). [Hint: Apply the Mayer-Vietoris sequences.]

## The Degree of a Proper Map

As an application of the Poincaré lemma for compact supports we introduce here a $C^{\infty}$ invariant of a proper map between two Euclidean spaces of the same dimension. Later, after Poincaré duality, this will be generalized to a proper map between any two oriented manifolds; for compact manifolds the properness assumption is of course redundant.

Let $f: \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$ be a proper map. Then the pullback $f^{*}: H_{c}^{n}\left(\mathbb{R}^{n}\right) \rightarrow$ $H_{c}^{\prime \prime}\left(\mathbb{R}^{\prime \prime}\right)$ is defined. It carries a generator of $H_{c}^{\prime \prime}\left(\mathbb{R}^{n}\right)$, i.e., a compactly supported closed form with total integral one, to some multiple of the generator. This multiple is defined to be the degree of $f$. If $\alpha$ is a generator of $H_{c}^{\prime \prime}\left(\mathbb{R}^{\prime \prime}\right)$, then

$$
\operatorname{deg} f=\int_{\mathbf{R}} f^{*} \alpha
$$

A priori the degree of a proper map is a real number; surprisingly, it turns out to be an integer. To see this, we need Sard's theorem. Recall that a critical point of a smooth map $f: \mathbb{R}^{m} \rightarrow \mathbb{R}^{m}$ is a point $p$ where the differential $\left(f_{*}\right)_{p}: T_{p} \mathbb{R}^{n} \rightarrow T_{f(p)} \mathbb{R}^{n}$ is not surjective, and a critical value is the image of a critical point. A point of $\mathbb{R}^{n}$ which is not a critical value is called a regular value. According to this definition any point of $\mathbb{R}^{n}$ which is not in the image of $f$ is a regular value so that the inverse image of a regular value may be empty.

Figure 4.3

Theprem 4.9 (Sard's Theorem for $\mathbb{R}^{n}$ ). The set of critical values of a smooth mapf $: \mathbb{R}^{m} \rightarrow \mathbb{R}^{n}$ has measure zero in $\mathbb{R}^{n}$ for any integers $m$ and $n$.

This means that given any $\varepsilon>0$, the set of critical values can be covered by cubes with total volume less than $\varepsilon$. Important special cases of this theorem were first published by A. P. Morse [1]. Sard's proof of the general case may be found in Sard [1].

Proposition 4.10 Let $f: \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$ be a proper map. If $f$ is not surjective, then it has degree 0.

Proof. Since the image of a proper map is closed (why?), if $f$ misses a point $q$, it must miss some neighborhood $U$ of $q$. Choose a bump $n$-form $\alpha$ whose support lies in $U$. Then $f^{*} \alpha \equiv 0$ so that $\operatorname{deg} f=0$.

Exercise 4.10.1. Prove that the image of a proper map is closed.
So to show that the degree is an integer we only need to look at surjective proper maps from $\mathbb{R}^{n}$ to $\mathbb{R}^{n}$. By Sard's theorem, almost all points in the image of such a map are regular values. Pick one regular value, say q. By hypothesis the inverse image of $q$ is nonempty. Since in our case the two Euclidean spaces have the same dimension, the differential $f_{*}$ is surjective if and only if it is an isomorphism. So by the inverse function theorem, around any point in the pre-image of $q, f$ is a local diffeomorphism. It follows that $f^{-1}(q)$ is a discrete set of points. Since $f$ is proper, $f^{-1}(q)$ is in fact a finite set of points. Choose a generator $\alpha$ of $\boldsymbol{H}^{( }\left(\mathbf{R}^{\prime \prime}\right)$ whose support is localized near $q$. Then $f^{*} \alpha$ is an $n$-form whose support is localized near the points of $f^{-1}(q)$ (see Figure 4.4). As noted carlier, a diffeomorphisn preserves an integral only up to sign, so the integral of $f^{*} \alpha$ near each point of $f^{-1}(q)$ is $\pm 1$. Thus

$$
\int_{R_{0}} f^{*} \alpha=\sum_{f^{-1}(Q)} \pm 1
$$

This proves that the degree of a proper map between two Euclidean spaces of the same dimension is an integer. More precisely, it shows that the number:of

Figure 4.4
points, counted with multiplicity $\pm 1$, in the inverse image of any regular value is the same for all regular values and that this number is equal to the degree of . the map.

Sard's theorem for $\mathbb{R}^{n}$, a key ingredient of this discussion, has a natural extension to manifolds. We take this opportunity to state Sard's'theorem in general. A subset $S$ of a manifold $M$ is said to have measure zero if it can be covered by countably many coordinate open sets $U_{i}$ such that $\phi_{i}\left(S \cap U_{i}\right)$ has measure zero in $\mathbb{R}^{n}$; here $\phi_{l}$ is the trivialization on $U_{i}$. A critical point of a smooth map $f: M \rightarrow N$ between two manifolds is a point $p$ in $M$ where the differential $\left(f_{*}\right)_{p}: T_{p} M \rightarrow T_{f(p)} N$ is not surjective, and a critical value is the image of a critical point.

Theorem 4.11 (Sard's Theorem). The set of critical values of a smooth map $f: M \rightarrow N$ has measure zero.

Exercise 4.11.1. Prove Theorem 4.11 from Sard's theorem for $\mathbf{R}^{\boldsymbol{n}}$.

## $\S 5$ The Mayer-Vietoris Argument

The Mayer-Vietoris sequence relates the cohomology of a union to those of the subsets. Together with the Five Lemma, this gives a method of proof which proceeds by induction on the cardinality of an open cover, called the Mayer-Vietoris argument. As evidence of its power and versatility, we derive from it the finite dimensionality of the de Rham cohomology, Poincare duality, the Künneth formula, the Leray-Hirsch theorem, and the Thom isomorphism, all for manifolds with finite good covero

## Existence of a Good Cover

Let $M$ be a manifold of dimension $n$. An open cover $\mathfrak{U}=\left\{U_{\alpha}\right\}$ of $M$ is called a good cover if all finite intersections $U_{a_{0}} \cap \cdots \cap U_{a,}$ are diffeomorphic to $R^{n}$. A manifold which has a finite good cover is said to be of finite type.

Theorem 5.1. Every manifold has a good cover. If the manifold is compact, then the cover may be chosen to be finite.

To prove this theorem we will need a little differential geometry. A Riemannian structure on a manifold $M$ is a smoothly varying metric 〈, > on the tangent späce of $M$ at each point; it is smoothly varying in the following sense: if $X$ and $Y$ are two smooth vector fields on $M$, then $\langle X, Y\rangle$ is a smooth function on $M$. Every manifold can be given a Riemannian structure by the following splicing procedure. Let $\left\{U_{s}\right\}$ be a
coordinate open cover of $M,\langle,\rangle_{a}$ a Riemanniad metric on $U_{a}$, and $\left\{\rho_{a}\right\}$ a partition of unity subordinate to $\left\{U_{\alpha}\right\}$. Then $\langle, \cdot\rangle=\sum \rho_{\alpha}\langle,\rangle_{a}$ is a Riemannian metric on $M$.

Proof of Theorem 5.1. Endow M with a Riemannian structure. Now we quote the theorem in differential geometry that every point in a Riemannian manifold has a geodesically convex neighborhood (Spivak [1, Ex. 32(f), p. 491]). The intersection of any two such neighborhoods is again geodesically convex. Since a geodesically convex neighborhood in a Riemannian manifold of dimension $n$ is diffeomorphic to $\mathbf{R}^{n}$, an open cover consisting of geodesically convex neighborhoods will be a good cover.

Given two covers $\mathfrak{U}=\left\{U_{\alpha}\right\}_{\alpha \in I}$ and $\mathfrak{B}=\left\{V_{\beta}\right\}_{\beta_{e}}$, if every $V_{p}$ is contained in some $U_{a}$, we say that $\mathfrak{B}$ is a refinement of $\mathfrak{u}$ and write $\mathfrak{u}>\boldsymbol{8}$. To be more precise we specify a refinement by a map $\phi: J \rightarrow 1$ such that $V_{B} \subset U_{\phi(\beta)}$. By a slight modification of the above proof we can show that every open cover on a manifold has a refinement which is a good cover: simply take the geodesically convex neighborhoods around cach point to be inside some open set of the given cover.

A directed set is a set $I$ with a partial order $>$ such that for any two elements $a$ and $b$ in $I$, there is an element $c$ with $a>c$ and $b>c$. The set of open covers on a manifold is a directed set, since any two open covers always have a common refinement. A subset $J$ of a directed set $I$ is cofinal in $I$ if for every $i$ in $I$ there is a $j$ in $J$ such that $i>j$. It is clear that $J$ 家 also a directed set.

Corollary 5.2. The good covers are cofinal in the set of all covers of a manifold $M$.

## Finite Dimensionality of de Rham Cohomology

Proposition 5.3.1. If the manifold $M$ has a finite good cover, then its cohomology is finite dimensiañal.

Proof. From the Mayer-Vietoris sequence

$$
\cdots \rightarrow H^{\bullet^{-1}}(U \cap V) \stackrel{\oplus}{\rightarrow} H^{q}(U \cup V) \stackrel{\ominus}{\rightarrow} H^{4}(U) \oplus H^{q}(V \rightarrow \cdots
$$

we get

$$
H^{q}\left(U \cup V \simeq \operatorname{ker} r \oplus \operatorname{im} r \simeq \operatorname{im} d^{*} \oplus \operatorname{im} r\right.
$$

Thus,
(*) if the qth cohomology of $U, V$, and $U \cap V$ are finite dimensional, then so is she gth cohomology of $U \cup V$.

For a manifold which is diffeomorphic to $R^{n}$, the finite dimensionality of
$H^{*}(M)$ follows from the Poincare lemma (41.1). We now proceed by induction on the cardinality of a good cover. Suppose the cohomology of any manifold having a good cover with at most $p$ open sets is finite dimensional. Consider a manifold having a good cover $\left\{U_{0}, \ldots, U_{p}\right\}$ with $p+1$ open sets. Now $\left(U_{0} \cup \ldots \cup U_{p-1}\right) \cap U_{p}$ has a good cover with $p$ open sets, namely $\left\{U_{0 p}, U_{1 p}, \ldots, U_{p-1 . p}\right\}$. By hypothesis, the $q t h$ cohomology of $U_{0} \cup \ldots \cup U_{p-1}, U_{p}$ and $\left(U_{0} \cup \ldots \cup U_{p-1}\right) \cap U_{p}$ are finite dimensional; from Remark $\left(^{*}\right.$ ), so is the $q$ th cohomology of $U_{0} \cup \ldots \cup U_{p}$. This completes the induction.

## Similarly,

Proposition 5.3.2. If the manifold $M$ has a finite good cover, then its compact cohomology is finite dimensional.

## Poincaré Duality on an Orientable Manifold

A pairing between two finite-dimensional vector spaces

$$
\langle,\rangle: V \otimes W \rightarrow \mathbb{R}
$$

is said to be nondegenerate if $\langle v, w\rangle=0$ for all $w$ implies $v=0$; equivalently, the map $v \mapsto\langle v$,$\rangle should define an isomorphism V \leadsto W^{*}$.

Because the wedge product is an antiderivation, it descends to cohomology; by Stokes' theorem, integration also descends to cohomology. So for an oriented manifold $M$ there is a pairing

$$
\int: H^{q}(M) \otimes H_{c}^{n-q}(M) \rightarrow \mathbb{R}
$$

given by the integral of the wedge product of two forms. Our first version of Poincare duality asserts that this pairing is nondegenerate whenever $M$ is orientable and has a finitegood cover; equivalently,

$$
\begin{equation*}
H^{q}(M) \simeq\left(H_{c}^{n-q}(M)\right)^{*} \tag{5.4}
\end{equation*}
$$

Note that by (5.3.1) and (5.3.2) both $H^{q}(M)$ and $H_{c}^{n-q}(M)$ are finitedimensional.

A couple of lemmas will be needed in the proof of Poincaré duality.
Exercise 5.5. Prove the Five Lemma: given a commutative diagram of Abelian groups

in which the rows are exact, if the maps $\alpha, \beta, \delta$ and $\varepsilon$ are isomorphisms, then so is the middle one $\gamma$.

Lemma 5.6. The two Mayer-Vietoris sequences (2.4) and (2,8) may be paired together to form a sign-commutative diagram

Here sign-commutativity means, for instance, that

$$
\int_{U \cap V} \omega \wedge d_{*} \tau= \pm \int_{U \cup V}\left(d^{*} \omega\right) \wedge \tau
$$

for $\omega \in H^{q}(U \cap V), \tau \in H_{c}^{n-9-1}(U \cup V)$. This lemma is equivalent to saying that the pairing induces a map from the upper exact sequence to the dual of the lower exact sequence such that the following diagram is signcommutative:

Proof. The first two squares are in fact commutative as is straightforward to check. We will show the sign-commutativity of the third square.

Recall from (2.5) and (2.7) that $d^{*} \omega$ is a form in $H^{+1}(U \cup V$ such that ,

$$
\begin{aligned}
& \left.d^{*} \omega\right|_{V}=-d\left(\rho_{V} \omega\right) \\
& \left.d^{*} \omega\right|_{V}=d\left(\rho_{U} \omega\right),
\end{aligned}
$$

and $d_{*} \tau$ is a form in $H_{c}^{n-a}(U \cap V)$ such that

$$
\text { (-(extension by } \left.\left.\left.0 \text { of } d_{*} \tau \text { to } U\right)_{,} \text {(extension by } 0 \text { of } d_{*} \tau \text { to } V\right)\right)
$$

$$
=\left(d\left(\rho_{v} \tau\right), d\left(\rho_{v} \tau\right)\right)
$$

Note that $d\left(\rho_{V} \tau\right)=\left(d \rho_{v}\right) \tau$ because $\tau$ is closed; similarly, $d\left(\rho_{V} \omega\right)=\left(d \rho_{v}\right) \omega$.

$$
\int_{U_{n} V} \omega \wedge d_{*} \tau=\int_{U_{n} V} \omega \wedge\left(d \rho_{V}\right) \tau=(-1)^{\operatorname{deg} \omega} \int_{U_{n V}}\left(d \rho_{V}\right) \omega \wedge \tau
$$

Since $d^{*} \omega$ has support in $U \cap V$,

$$
\int_{U \cup V} d^{*} \omega \wedge \tau=-\int_{U_{\cap V}}\left(d \rho_{V}\right) \omega \wedge \tau
$$

Therefore,

$$
\int_{U \cap V} \omega \wedge d_{*} \tau=(-1)^{\operatorname{des} \omega+1} \int_{U \cup V} d^{*} \omega \wedge \tau
$$

By the Five Lemma if Poincare duality holds for $U, V$, and $U \cap V$, then it holds for $U \cup V$. We now proceed by induction on the cardinality of a good cover. For $M$ diffeomorphic to $\mathbb{R}^{n}$, Poincaré duality follows from the two Poincaré lemmas

$$
H^{*}\left(\mathbb{R}^{N}\right)= \begin{cases}\mathbb{R} & \text { in dimension } 0 \\ 0 & \text { elsewhere }\end{cases}
$$

and

$$
H_{c}^{*}\left(\mathbb{R}^{n}\right)= \begin{cases}\mathbb{R} & \text { in dimension } n \\ 0 & \text { elsewhere }\end{cases}
$$

Next suppose Poincaré duality holds for any manifold having a good cover with at most $p$ open sets, and consider a manifold having a good cover $\left\{U_{0}, \ldots, U_{p}\right\}$ with $p+1$ open sets. Now ( $U_{0} \cup \cdots \cup U_{p-1}$ ) $\cap U_{p}$ has a good cover with $p$ open sets, namely $\left\{U_{0 p}, U_{i p}, \ldots, U_{p-1, p}\right\}$. By hypothesis Poincaré duality holds for $U_{0} \cup \ldots \cup U_{p-1}, \quad U_{p}$, and $\left(U_{0} \cup \ldots \cup U_{p-1}\right)$ $\cap U_{p}$, so it holds for $U_{0} \cup \ldots \cup U_{p-1} \cup U_{p}$ as well. This induction argument proves Poincaré duality for any orientable manifold having a finite good cover.

Remark 5.7. The finiteness assumption on the good cover is in fact not necessary. By a closer analysis of the topology of a manifold, the MayerVietoris argument above can be extended to any orientable manifold (Greub, Halperin, and Vanstone [1, p. 198 and p. 14]). The statement is as follows: if $M$ is an orientable manifold of dimension $n$, whose cohomology is not necessarily finite dimensional, then

$$
H^{q}(M) \simeq\left(H_{c}^{n-q}(M)\right)^{*} \quad, \quad \text { for any integer } q .
$$

However, the reverse implication $H_{c}^{q}(M) \simeq\left(H^{n-q}(M)\right)^{*}$ is not always true. The asymmetry comes from the fact that the dual of a direct sum is a direct product, but the dual of a direct product is not a direct sum. For example, consider the infinite disjoint union

$$
M=\coprod_{i=1}^{\infty} M_{i}
$$

where the $M_{i}$ 's are all manifolds of finite type of the same dimension $n$. Then the de Rham cohomology is a direct product

$$
\begin{equation*}
H^{q}(M)=\prod_{i} H^{q}\left(M_{i}\right) \tag{5.7.1}
\end{equation*}
$$

but the compact cohomology is a direct sum

$$
\begin{equation*}
H_{c}^{q}(M)=\bigoplus_{i} H_{c}^{q}\left(M_{i}\right) . \tag{5.7.2}
\end{equation*}
$$

Taking the dual of the compact cohomology $H_{c}^{q}(M)$ gives a direct product

$$
\begin{equation*}
\left(H_{c}^{q}(M)\right)^{*}=\prod_{i} H_{c}^{q}\left(M_{i}\right) \tag{5.7.3}
\end{equation*}
$$

So by (5.7.1) and (5.7.3), it follows from Poincare duality for the manifolds of finite type $M_{i}$, that

$$
H^{q}(M)=\left(H_{c}^{n-q}(M)\right)^{*} .
$$

Corollary 5.8. If $M$ is a connected oriented manifold of dimension $n$, then $H_{c}^{u}(M) \simeq \mathbb{R}$. In particular if $M$ is compact oriented and connected, $H^{n}(M) \simeq \mathbb{R}$.

Let $f: M \rightarrow N$ be a map between two compact oriented manifolds of dimension $n$. Then there is an induced map in cohomology

$$
f^{*}: H^{\prime \prime}(N) \rightarrow H^{\prime \prime}(M)
$$

The degree of $f$ is defined to be $\int_{M} f^{*} \omega$, where $\omega$ is the generator of $H^{n}(N)$. By the same argument as for the degree of a proper map between two Euclidean spaces, the degree of a map between two compact oriented manifolds is an integer and is equal to the number of points, counted with multiplicity $\pm 1$, in the inverse image of any regular point in $\boldsymbol{N}$.

The Künneth Formula and the Leray-Hirsch Theorem
The Künneth formula states that the cohomology of the product of two manifolds $M$ and $F$ is the tensor product

$$
\begin{equation*}
H^{*}(M \times F)=H^{*}(M) \otimes H^{*}(F) \tag{5.9}
\end{equation*}
$$

This means

$$
\dot{H}^{n}(M \times F)=\bigoplus_{p+q=n} H^{r}(M) \otimes H^{4}(F) \quad \text { for every } n
$$

More generally we are interested in the cohomology of a fiber bundle.
Definition. Let $G$ be a topological group which acts effectivoly on a space $F$ on the left. A surjection $\pi: E \rightarrow B$ between topological spaces is a fiber bundle with fiber $F$ and structure group. $G$ if $M$ has an open coyer $\{U\}$ \} such that there are homeomorphisms

$$
\phi_{a}:\left.E\right|_{v_{a}} \simeq U_{a} \times F
$$

and the transitions functions are.contunuous functions with values in $G$ :

$$
g_{a \beta}(x)=\left.\phi_{a} \phi_{\beta}^{-1}\right|_{(x \mid \times F} \in G .
$$

Sometimes the total space $E$ is referred to as the fiber bundle. A fiber bundle with structure group $G$ is also called a $G$-bundle. If $x \in B$, the set $E_{x}=\pi^{-1}(x)$ is called the fiber at $x$.

Since we are working with de Rham theory, the spaces $E, B$, and $F$ will be assumed to be $C^{\infty}$ manifolds and the maps $C^{\infty}$ maps. We may also speak of a fiber bundle without mentioning its structure group; in that case, the group is understood to be the group of diffeomorphisms of $F$, denoted $\operatorname{Diff}(F)$.

Remark. The action of a group $G$ on a space $F$ is said to be effective if the only element of $G$ which acts trivially on $F$ is the identity, i.e., if $g \cdot y=y$ for all $y$ in $F$, then $g=1 \in G$. In the $C^{\infty}$ case, this is equivalent to saying that the kernel of the natural map $G \rightarrow \operatorname{Diff}(F)$ is the identity or that $G$ is a subgroup of $\operatorname{Diff}(F)$, the group of diffeomorphisms of $F$. In the definition of a fiber bundle the action of $G$ on $F$ is required to be effective in order that the diffeomorphism

$$
\left.\phi_{a} \phi_{b}^{-1}\right|_{(x) \times F}
$$

of $F$ can be identified unambiguously with an element of $G$.
The transition functions $g_{a p}: U_{a} \cap U_{\beta} \rightarrow G$ satisfy the cocycle condition:

$$
g_{\alpha \beta} \cdot g_{\beta \gamma}=g_{\alpha \gamma}
$$

Given a cocycle $\left\{g_{a \beta}\right\}$ with values in $G$ we can construct a fiber bundle $E$ having $\left\{g_{\alpha \beta}\right\}$ as its transition functions by setting

$$
\begin{equation*}
E=\left(\amalg U_{a} \times F\right) /(x, y) L\left(x, g_{a f}(x) y\right) \tag{5.10}
\end{equation*}
$$

for $(\dot{x}, y)$ in $U_{a} \times F$ and $\left(x, g_{a d}(x) y\right)$ in $U_{a} \times F$.
The following proof of the Künneth formula assumes that $M$ has a finite good cover. This assumption is necessary for the induction argument.

The two natural projections

give rise to a map on forms

$$
\omega \otimes \phi \mapsto \pi^{*} \omega \wedge \rho^{*} \phi
$$

which induces a map in cohomology (exercise)

$$
\psi: H^{*}(M) \otimes H^{*}(F) \rightarrow H^{*}(M \times F) .
$$

We will show that $\psi$ is an isomorphism.
If $M=\mathbb{R}^{n}$, this is simply the Poincaré lemma.
In the following we will regard $M \times F$ as a product bundle over $M$. Let $U$ and $V$ be open sets in $M$ and $n$ a fixed integer. From the Mayer-Vietoris sequence

$$
\cdots \rightarrow H^{p}(U \cup V) \rightarrow H^{p}(U) \oplus H^{p}(V) \rightarrow H^{p}(U \cap V \cdots
$$

we get an exact sequence by tensoring with $H^{n-p}(F)$
$\cdots \rightarrow H^{p}(U \cup V) \otimes H^{n-p}(F) \rightarrow\left(H^{p}(U) \otimes H^{n-p}(F)\right) \oplus\left(H^{p}(V) \otimes H^{n-p}(F)\right)$

$$
\rightarrow H^{p}(U \cap V) \otimes H^{n-p}(F) \rightarrow \cdots
$$

since tensoring with a vector space preserves exactness. Summing over $p=0, \ldots, n$, yields the exact sequence

$$
\begin{aligned}
\cdots & \rightarrow \oplus_{p=0}^{n} H^{p}(U \cup V) \otimes H^{n-p}(F) \\
& \rightarrow \oplus_{p=0}^{n}\left(H^{p}(U) \otimes H^{n-p}(F)\right) \oplus\left(H^{p}(V) \otimes H^{n^{-p}}(F)\right) \\
& \rightarrow \oplus_{D=0}^{\not \oplus} H^{p}(U \cap V) \otimes H^{n-p}(F) \rightarrow \cdots .
\end{aligned}
$$

The following diagram is commutative

The commutativity is clear except possibly for the square $\oplus\left(H^{p}(U \cap V) \otimes H^{n-p}(F)\right) \xrightarrow{d} \oplus H^{p+1}(U \cup V) \otimes H^{n-p}(F)$

$$
\begin{gathered}
|\psi| \\
H^{*}((U \cap V) \times F) \xrightarrow{c} H^{m}((U \cup V) \times F,
\end{gathered}
$$

which we now check. Let $\omega \otimes \phi$ be in $H^{p}(U \cap V) \otimes H^{n-p}(F)$. Then

$$
\begin{aligned}
& \psi d^{*}(\omega \otimes \phi)=\pi^{*}\left(d^{*} \omega\right) \wedge \rho^{*} \phi \\
& d^{*} \psi(\omega \otimes \phi)=d^{*}\left(\pi^{*} \omega \wedge \rho^{*} \phi\right) .
\end{aligned}
$$

Recall from (2.5) that if $\left\{\rho_{U}, \rho_{V}\right\}$ is a partition of unity subordinate to $\{U, V\}$ then

$$
d^{*} \omega=\left\{\begin{array}{rll}
-d\left(\rho_{V} \omega\right) & \text { on } & U \\
d\left(\rho_{U} \omega\right) & \text { on } & V
\end{array}\right.
$$

Since the pullback functions $\left\{\pi^{*} \rho_{U}, \pi^{*} \rho_{V}\right\}$ form a partition of unity on $(U \cup V) \times F$ subordinate to the cover $\{U \times F, V \times F\}$, on $(U \cap V) \times F$

$$
\begin{aligned}
d^{*}\left(\pi^{*} \omega \wedge \rho^{*} \phi\right) & =d\left(\left(\pi^{*} \rho_{U}\right) \pi^{*} \omega \wedge \rho^{*} \phi\right) \\
& =\left(d \pi^{*}\left(\rho_{U} \omega\right)\right) \wedge \rho^{*} \phi \quad \text { since } \phi \text { is closed } \\
& =\pi^{*}\left(d^{*} \omega\right) \wedge \rho^{*} \phi
\end{aligned}
$$

So the diagram is commutative.
By the Five Lemma if the theorem is true for $U, V$, and $U \cap V$, then it is also true for $U \cup V$. The Künneth formula now follows by induction on the cardinality of a good cover, as in the proof of Poincare duality.

Let $\pi: E \rightarrow M$ be a fiber bundle with fiber $F$. Suppose there are cohomology classes $e_{1}, \ldots, e_{r}$ on $E$ which restrict to a basis of the cohomology of each fiber. Then we can define a map

$$
\psi: H^{*}(M) \otimes \mathbf{R}\left\{e_{1}, \ldots, e_{r}\right\} \rightarrow H^{*}(E)
$$

The same argument as the Künneth formula gives
Theorem 5.11 (Leray-Hirsch). Let $E$ be a fiber bundle over $M$ with fiber $F$. Suppose $M$ has a finite good cover. If there are global cohomology classes $e_{1}, \ldots, e_{r}$ on $E$ which when restricted to each fiber freely generate the cohomology of the fiber, then $H^{*}(E)$ is a free module over $H^{*}(M)$ with basis $\left\{e_{1}, \ldots\right.$, $\left.e_{r}\right\}$, i.e.

$$
H^{*}(E) \simeq H^{*}(M) \otimes \mathbf{R}\left\{e_{1}, \ldots, e_{p}\right\} \simeq H^{*}(M) \otimes H^{*}(F)
$$

Exercise 5.12 Künneth formula for compact cohomology. The Künneth formula for compact cohomology states thăt for any manifolds $M$ and $N$ having a finite good cover.

$$
H_{c}^{*}(M \times N)=H_{c}^{*}(M) \otimes H_{c}^{*}(N)
$$

(a) In case $M$ and $N$ are orientable, show that this is a consequence of Poincaré duality and the Künneth formula for de Rham cohomology.
(b) Using the Mayer-Vietoris argument prove the Künneth formula for compact cohomology for any $M$ and $N$ having a finite good cover.

## The Poincaré Dual of a Closed Oriented Submanifold

Let $M$ be an oriented manifold of dimension $n$ and $S$ a closed oriented submanifold of dimension $k$; here by "closed" we mean as a subspace of $M$. Figure 5.1 is a closed submanifold of $\boldsymbol{R}^{2}-\{0\}$, but Figure 5-2 is not. To every closed oriented submanifold $i: S \hookrightarrow M$ of dimension $k$, one can associ-
ate a unique cohomology class $\left[\eta_{s}\right]$ in $H^{n-k}(M)$, called its Poincaré dual, as follows. Let $\omega$ be a closed $k$-form with compact support on $M$. Since $S$ is

Figure 5.1

Figure 5.2
closed in $M$, Supp $\left(\left.\omega\right|_{s}\right)$ is closed not only in $S$, but also in $M$. Now because $\operatorname{Supp}\left(\left.\omega\right|_{s}\right) \subset(\operatorname{Supp} \omega) \cap S$ is a closed subset of a compact set, $i^{*} \omega$ also has compact support on $S$, so the integral $\int_{s} i^{*} \omega$ is defined. By Stokes's theorem integration over $S$ induces a linear functional on $H_{c}^{*}(M)$. It follows by Poincaré duality: $\left(H_{c}^{k}(M)\right)^{*} \simeq H^{n-k}(M)$, that integration over $S$ corresponds to a unique cohomology class [ $\eta_{s}$ ] in $H^{n-k}(M)$. We will often call both the cohomology class $\left[\eta_{s}\right]$ and a form representing it the Poincaré dual of $S$. By definition the Poincare dual $\eta_{s}$ is the unique cohomology class in $H^{-k}(M)$ satisfying

$$
\begin{equation*}
\int_{S} i^{*} \omega=\int_{M} \omega \wedge \eta_{S} \tag{5.1}
\end{equation*}
$$

for any $\omega$ in $H_{c}^{\star}(M)$.
Now suppose $S$ is a compact oriented submanifold of dimension $k$ in $M$. Since a compact subset of a Hausdorff space is closed, $S$ is also a closed oriented submanifold and hence has a Poincare dual $\eta_{s} \in H^{n-k}(M)$. This $\eta_{s}$ we will call the closed Poincare dual of $S$, to distinguish it from the compact Poincaré dual to be defined below. Because $S$ is compact, one can in fact integrate over $S$ not only $k$-forms with compact support on $M$, but any $k$-form on $M$. In this way $S$ defines a linear functional on $H^{k}(M)$, and so by Poincaré duality corresponds to a unique cohomology class [ $\eta_{s}^{\prime}$ ] in $H_{c}^{n-k}(M)$, the compact Poincaré dual of $S$. We must assume here that $M$ has a finite good cover; otherwise, the duality $\left(H^{k}(M)\right)^{*} \simeq H_{c}^{n-k}(M)$ does not hold. The compact Poincare dual $\left[\eta^{\prime}\right.$ '] is uniquely characterized by

$$
\begin{equation*}
\int_{S} i^{*} \omega=\int_{M} \omega \wedge \eta_{S}^{\prime}, \tag{5.14}
\end{equation*}
$$

for any $\omega \in H^{k}(M)$. If (5.14) holds for any closed $k$-form $\omega$, then it certainly holds for any closed $k$-form $\omega$ with compact support. So as a form, $\eta^{\prime}$ s is also the closed Poincaré dual of $S$, i.e., the natural map $H_{c}^{n-k}(M) \rightarrow H^{n-k}(M)$ sends the compact Poincaré dual to the closed Poincaré dual. Therefore we can in fact demand the closed Poincaré dual of a compact oriented submanifold to have compact support. However, as cohomology classes, $\left[\eta_{s}\right] \in$ $H^{n-k}(M)$ and $\left[\eta_{s}^{\prime}\right] \in H_{c}^{n-k}(M)$ could be quite different, as the following examples demonstrate.

Example 5.15 (The Poincaré duais of a point $P$ on $\left.\mathbb{R}^{n}\right)$. Since $H^{n}\left(\mathbb{R}^{\prime \prime}\right)=0$, the closed Poincare dual $\eta_{P}$ is trivial and can be represented by any closed $n$-form on $R^{n}$, but the compact Poincare dual is the nontrivial class in $H_{c}^{\prime \prime}\left(\mathbf{R}^{n}\right)$ represented by a bump form with total integral 1.
Example-Exfrcise 5.16 (The ray and the circle in $\mathbb{R}^{2}-\{0\}$ ). Let $x, y$ be the standard coordinates and $r, \theta$ the polar coordinates on $\mathbb{R}^{2}-\{0\}$.
(a) Show that the Poincare dual of the ray $\{(x, 0) \mid x>0\}$ in $\mathbb{R}^{2}-\{0\}$ is $d \theta / 2 \pi$ in $H^{1}\left(\mathbf{R}^{2}-\{0\}\right)$.
(b) Show that the closed Poincare dual of the unit circle in $H^{1}\left(\mathbb{R}^{2}-\{0\}\right)$ is 0 , but the compact Poincare dual is the nontrivial generator $\rho(r) d r$ in $H_{c}^{1}\left(\boldsymbol{R}^{2}-\{0\}\right)$ where $\rho(r)$ is a bump function with total integral 1 . (By a bump function we mean a smooth function whose support is contained in some disc and whose graph looks like a "bump".)

Thus the generator of $H^{1}\left(\mathbb{R}^{2}-\{0\}\right)$ is represented by the ray and the generator of $\boldsymbol{H}_{c}^{1}\left(\mathbb{R}^{2}-\{0\}\right)$ by the circle (see Figure 5.3).

Remark 5.17. The two Poincaré duals of a compact oriented submanifold correspond to the two homology theories-closed homology and compact homology. Closed homology has now fallen into disuse, while compact homology is known these days as the homology of singular chains. In Example-Exercise 5.16, the generator of $H_{1, \text { closed }}\left(\mathbb{R}^{2}-\{0\}\right)$ is the ray, while the generator of $H_{1 \text {, compact }}\left(R^{2}-\{0\}\right)$ is the circle. (The circle is a boundary in closed homology since the punctured closed disk is a closed 2-chain in $\mathbf{R}^{\mathbf{2}}-\{0\}$.) In general Poincaré duality sets up an isomorphism between closed homology and de Rham cohomology, and between compact homology and compact de Rham cohomology.

Let $S$ be a compact oriented submanifold of dimension $k$ in $M$. If $W \subset M$ is an open subset containing $S$, then the compact Poincare dual of $S$ in $W, \eta_{S, W}^{\prime} \in H_{c}^{n-k}(W)$, extends by 0 to a form $\eta_{s}^{\prime}$ in $H_{c}^{n-k}(M)$. $\eta_{s}$ is clearly the compact Poincare dual of $S$ in $M$ because

$$
\int_{S} i^{*} \omega=\int_{W} \omega \wedge \eta_{S, W}^{\prime}=\int_{M} \omega \wedge \eta_{S}^{\prime}
$$

Figure 5.3

Thus, the support of the compact Poincare dual of $S$ in $M$ may be shrunk into any open neighborhood of $S$. This is called the localization principle. For a noncompact closed oriented submanifold $S$ the localization principle also holds. We will take it up in Proposition 6.25.

In this book we will mean by the Poincaré dual the closed Poincaré dual. However, as we have seen, if the submanifold is compact, we can demand that its closed Poincare dual have compact support, even as a cohomology class in $H^{n-k}(M)$. Of course, on a compact manifold $M$, there is no distinction between the closed and the compact Poincaré duals.

## §6 The Thom Isomorphism

So far we have encountered two kinds of $C^{\infty}$ invariants of a manifold, de Rham cohomology and compactly supported cohomology. For vector bundles there is another invariant, namely, cohomology with compact support in the vertical direction. The Thom isomorphism is a statement about this last-named cohomology. In this section we use the Mayer-Vietoris argument to prove the Thom isomorphism for an orientable vector bundle. We then explain why the Poincare dual and the Thom class are in fact one and the same thing.' Using the interpretation of the Poincare dual of a submanifold as the Thom class of the normal bundle, it is easy to write down explicitly the Poincare dual, at least when the normal bundle is trivial. Next we give an explicit construction of the Thom class for an oriented rank 2 bundle, introducing along the way the global angular form and the Euler class. The higher-rank analogues will be taken up in Sections 11 and 12. We conclude this section with a brief discussion of the relative de Rham theory, citing the Thom class as an example of a relative class.

## Vector Bundles and the Reduction of Structure Groups

Let $\pi: E \rightarrow M$ be a surjective map of manifolds whase fiber $\pi^{-1}(x)$ is a vector space for every $x$ in $M$. The map $\pi$ is, $C^{\infty}$ real vector bundle of rank $n$ if there is an open cover $\left\{U_{\alpha}\right\}$ of $M$ and fiber-preserving diffeomorphisms

$$
\phi_{a}:\left.E\right|_{U_{a}}=\pi^{-1}\left(U_{\alpha}\right) \simeq U_{a} \times \mathbf{R}^{n}
$$

which are linear isomorphisms on each fiber. The maps

$$
\phi_{\alpha} \circ \phi_{\beta}^{-1}:\left(U_{\alpha} \cap U_{\beta}\right) \times \mathbb{R}^{n} \rightarrow\left(U_{\alpha} \cap U_{\beta}\right) \times \mathbb{R}^{n}
$$

are vector-space automorphisms of $\mathbb{R}^{n}$ in each fiber and hence give rise to maps

$$
\begin{gathered}
g_{\alpha \beta}: U_{a} \cap U_{\beta} \rightarrow G L(n, R) \\
g_{a \beta}(x)=\left.\phi_{a} \phi_{\beta-1}\right|_{(x) \times R} .
\end{gathered}
$$

In the terminology of Section 5 a vector bundle of rank $n$ is a fiber bundle with fiber $\mathbb{R}^{n}$ and structure group $G L(n, R)$. If the fiber is $C^{n}$ and the
structure group is $G L(n, \mathbb{C})$, the vector bundle is a complex vector bundle. Unless otherwise stated, by a vector bundle we mean a $C^{\infty}$ real vector bundle.

Let $U$ be an open set in $M$. A map $s: U \rightarrow E$ is a section of the vector bundle $E$ over $U$ if $\pi v s$ is the identity on $U$. The space of all sections over $U$ is written $\Gamma(U, E)$. Note that every vector bundle has a well-defined global zero section. A collection of sections $s_{1}, \ldots, s_{n}$ over an open set $U$ in $M$ is a frame on $U$ if for every point $x$ in $U, s_{1}(x), \ldots, s_{n}(x)$ form a basis of the vector space $E_{x}=\pi^{-1}(x)$.

The transition functions $\left\{g_{\alpha \beta}\right\}$ of a vector bundle satisfy the cocycle condition

$$
g_{\alpha \beta} \circ g_{\beta \gamma}=g_{\alpha \gamma} \quad \text { on } \quad U_{\alpha} \cap U_{\beta} \cap U_{\gamma}
$$

The cocycle $\left\{g_{\alpha \beta}\right\}$ depends on the choice of the trivialization.
Lemma 6.1. If the cocycle $\left\{y_{x \beta}^{\prime}\right\}$ comes from another trivialization $\left\{\phi_{a}^{\prime}\right\}$, then there exist maps $\lambda_{a}: U_{a} \rightarrow G L(n, \mathbb{R})$ such that

$$
g_{\alpha \beta}=\lambda_{a} g_{\alpha \beta}^{\prime} \lambda_{\beta}^{-1} \quad \text { on } \quad U_{a} \cap U_{\beta}
$$

Proof. The two trivializations differ by a nonsingular transformation of $\mathbb{R}^{n}$ at each point:

$$
\phi_{a}=\lambda_{a} \phi_{a}^{\prime}, \lambda_{a}: U_{a} \rightarrow G L(n, \mathbb{R}) .
$$

Therefore,

$$
g_{\alpha \beta}=\dot{\phi}_{a} \dot{\phi}_{\beta}^{-1}=\lambda_{a} \dot{\phi}_{\beta}^{\prime} \dot{\phi}_{\beta}^{-!} \lambda_{\beta}^{-1}=\lambda_{a} g_{\alpha \beta}^{\prime} \lambda_{\beta}^{-1}
$$

Two cocycles related in this way are said to be equivalent.
Given a cocycle $\left\{g_{a \beta}\right\}$ with values in $G L(n, \mathbb{R})$ we can construct a vector bundle $E$ having $\left\{g_{a \beta}\right\}$ as its cocycle as in (5.10). A homomorphism between two vector bundles, called a bundle map, is a fiber-preserving smooth map $f: E \rightarrow E^{\prime}$ which is linear on corresponding fibers.

Exercise 6.2. Show that two vector bundles on $M$ are isomorphic if and only if their cocycles relative to some open cover are equivalent.

Given a vector bundle with cocycle $\left\{g_{\alpha \beta}\right\}$, if it is possible to find an equivalent cocycle with values in a subgroup $H$ of $G L(n, \mathbb{R})$, we say that the structure group of $E$ may be reduced to $H$. A vector bundle is orientable if its structure group may be reduced to $G L^{+}(n, \mathbb{R})$, the linear transformations of $\mathbb{R}^{n}$ with positive determinant. A trivialization $\left\{\left(U_{a}, \phi_{a}\right)\right\}_{\alpha, i}$ on $E$ is said to be oriented if for every $\alpha$ and $\beta$ in $I$, the transition function $g_{\alpha \beta}$ has positive determinant. Two oriented trivializations $\left\{\left(U_{\alpha}, \phi_{\alpha}\right)\right\},\left\{\left(V_{\beta}, \psi_{\beta}\right)\right\}$ are equivalent if for every $x$ in $U_{a} \cap V_{\beta}, \phi_{\alpha} \circ\left(\psi_{\beta}\right)^{-1}(x): \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$ has positive determinant. It is easily checked that this is an equivalence relation and that it
partitions all the oriented trivializations of the vector bundle $E$ ints two equivalence classes. Either equivalence class is called an orientation on the vector bundle $E$.

Example 6.3 (The tangent bundle). By attaching to each point $x$ in a manifold $M$, the tangent space to $M$ at $x$, we obtain the tangent bundle of $M$ :

$$
T_{M}=\bigcup_{x \in M} T_{x} M .
$$

Let $\left\{\left(U_{a}, \psi_{a}\right)\right\}$ be an atlas for $M$. The diffeomorphism

$$
\psi_{a}: U_{a} \neq \mathbb{R}^{n}
$$

induces a map
which gives a local trivialization of the tangent bundle $T_{\mathbf{N}}$. From this we see that the transition functions of $T_{M}$ are the Jacobians of the transition functions of $M$. Therefore $M$ is orientable if and only if its tangent bundle is. If $\psi_{a}=\left(x_{1}, \ldots, x_{n}\right)$, then $\partial / \partial x_{1}, \ldots, \partial / \partial x_{n}$ is a frame for $T_{M}$ over $U_{\alpha}$. In the language of bundles a smooth vector field on $U_{a}$ is a smooth section of the - tangent bundle over $U_{a}$.

We now show that the structure group of every real vector bundle $E$ may be reduced to the orthogonal group. First, we can endow $E$ with a Riemannian structure-a smoothly varying positive definite symmetric bilinear form on each fiber-as follows. Let $\left\{U_{a}\right\}$ be an open cover of $M$ which trivializes $E$. On each $U_{\alpha}$, choose a frame for $\left.E\right|_{\nu_{\varepsilon}}$ and declare it to be orthonormal. This defines a Riemannian structure on $\left.E\right|_{U_{a}}$ Let $\langle,\rangle_{a}$ denate this inner product on $\left.E\right|_{v_{a}}$. Now use a partition of unity $\left\{\rho_{a}\right\}$ to splice them together, i.e., form

$$
\langle,\rangle=\sum p_{a}\langle,\rangle_{a} .
$$

This will be an inner product over all of $M$.
As trivializations of $E$, we take only those maps $\phi_{a}$ that send orthonormal frames of $E$ (relative to the global metric $\rangle$,$\rangle ) to orthonormal frames$ of $\mathbb{R}^{n}$. Then the transition functions $g_{\alpha \beta}$ will preserve orthonormal frames and hence take values in the orthogonal group $O(n)$. If the determinant of $g_{\alpha \beta}$ is positive, $g_{\alpha \beta}$ will actually be in the special orthogonal group $S O(n)$. Thus

Proposition 6.4. The structure group of a real vector bundle of rank $n$ can always be reduced to $O(n)$; it can be reduced to $S O(n)$ if and only if the vector bundle is orientable.

Exercise 6.5. (a) Show that there is a direct product decomposition
$G L(n, \mathbb{R})=O(n) \times\{$ positive definite symmetric matrices $\}$.
(b) Use (a) to show that the structure group of any real vector bundle may be reduced to $O(n)$ by finding the $\lambda_{a}$ 's of Lemma 6.1.

## Operations on Vector Bundles

Apart from introducing the functorial operations on vector bundles, our main purpose here is to establish the triviality of a vector bundle over a contractible manifold, a fact needed in the proof of the Thom isomorphism.

Functorial operations on vector spaces carry over to vector bundles. For instance, if $E$ and $E^{\prime}$ are vector bundles over $M$ of rank $n$ and $m$ respectively, their direct sum $E \oplus E^{\prime}$ is the vector bundle over $M$ whose fiber at the point $x$ in $M$ is $E_{x} \oplus E_{x}^{\prime}$. The local trivializations $\left\{\phi_{\alpha}\right\}$ and $\left\{\phi_{a}^{\prime}\right\}$ for $E$ and $E^{\prime}$ induce a local trivialization for $E \oplus E^{\prime}$ :

$$
\phi_{\alpha} \oplus \phi_{\alpha}:\left.E \oplus E^{\prime}\right|_{U_{\alpha}} \simeq U_{\alpha} \times\left(\mathbb{R}^{n} \oplus \mathbb{R}^{m}\right)
$$

Hence the transition matrices for $E \oplus E^{\prime}$ are

$$
\left(\begin{array}{cc}
g_{\alpha \beta} & 0 \\
0 & g_{\alpha \beta}^{\prime}
\end{array}\right)
$$

Similarly we can define the tensor product $E \otimes E^{\prime}$, the dual $E^{*}$, and $\operatorname{Hom}\left(E, E^{\prime}\right)$. Note that $\operatorname{Hom}\left(E, E^{\prime}\right)$ is isomorphic to $E^{*} \otimes E^{\prime}$. The tensor product $E \otimes E^{\prime}$ clearly has transition matrices $\left\{g_{\alpha \beta} \otimes g_{\alpha \beta}^{\prime}\right\}$, but the transition matrices for the dual $E^{*}$ are not so immediate. Recall that the dual $V^{*}$ of a real vector space $V$ is the space of all linear functionals on $V$, i.e., $V^{*} \simeq \operatorname{Hom}(V, \mathbb{R})$, and that a linear map $f: V \rightarrow W$ induces a map $f^{t}:$ $W^{*} \rightarrow V^{*}$ represented by the transpose of the matrix of $f$. If

$$
\phi_{a}:\left.E\right|_{U_{a}} \leadsto U_{\alpha} \times \mathbb{R}^{n}
$$

is a trivialization for $E$, then

$$
\left(\phi_{a}^{\prime}\right)^{-1}:\left.E^{*}\right|_{U_{a}} \neq U_{a} \times\left(\mathbb{R}^{n}\right)^{*}
$$

is a trivialization for $E^{*}$. Therefore the transition functions of $E^{*}$ are

$$
\begin{equation*}
\left(\phi_{\alpha}^{i}\right)^{-1} \phi_{\beta}^{z}=\left(\left(\phi_{a} \dot{\phi_{\beta}^{-i}}\right)^{t}\right)^{-1}=\left(g_{\alpha \beta}^{t}\right)^{-1} \tag{6.6}
\end{equation*}
$$

Let $M$ and $N$ be manifolds and $\pi: E \rightarrow M$ a vector bundle over $M$. Any map $f: N \rightarrow M$ induces a vector bundle $f^{-1} E$ on $N$, called the pullback of $E$ byf. This bundle $f^{-1} E$ is defined to be the subset of $N \times E$ given by

$$
\{(n, e) \mid f(n)=\pi(e)\}
$$

It is the unique maximal subset of $N \times E$ which makes the following diagram commutative

The fiber of $f^{-1} E$ over a point $y$ in $N$ is isomorphic to $E_{f(v)}$. Since a product bundle pulls back to a product bundle we see that $f^{-1} E$ is locally trivial, and is therefore a vector bundle. Furthermore, if we have a composition

$$
M^{\prime \prime} \xrightarrow{\bullet} M^{\prime} \xrightarrow{\boldsymbol{S}} M,
$$

then

$$
(f \circ g)^{-1} E=g^{-1}\left(f^{-1} E\right)
$$

Let $\operatorname{Vect}_{k}(M)$ be the isomorphism classes of rank $k$ real vector bundles over $M$. It is a pointed set with base point the isomorphism class of the product bundle over $M$. If $f: M \rightarrow N$ is a map between two manifolds, let $\operatorname{Vect}_{k}(f)=f^{-1}$ be the pullback map on bundles. In this way, for each integer $k$, Vect ${ }_{k}$ ( ) becomes a functor from the category of manifolds and smooth maps to the category of pointed sets and base point preserving maps.

Remark 6.7 Let $\left\{U_{a}\right\}$ be a trivializing open cover for $E$ and $g_{a \beta}$ the transition functions. Then $\left\{f^{-1} U_{\alpha}\right\}$ is a trivializing open cover for $f^{-1} E$ over $N$ and $\left.\left(f^{-1} E\right)\right|_{f-1 v_{\alpha}} \simeq f^{-1}\left(\left.E\right|_{U_{\alpha}}\right)$. Therefore the transition functions for $f^{-1} E$ are the pullback functions $f^{*} g_{\alpha \beta}$.

A basic property of the pullback is the following.
Theorem 6.8 (Homotopy Property of Vector Bundles). Assume $Y$ to be a compact manifold. If $f_{0}$ and $f_{1}$ are homotopic maps from $Y$ to a manifold $X$ and $E$ is a vector bundle on $X$, then $f_{0}^{-1} E$ is isomorphic to $f_{1}^{-1} E$, i.e., homotopic maps induce isomorphic bundles.

Proof. The problem of constructing an isomorphism between two vector bundles $V$ and $W$ of rank $k$ over a space $B$ may be turned into a problem in cross-sectioning a fiber bundle over $B$, as follows. Recall that $\operatorname{Hom}(V, W)=V^{*} \otimes W$ is a vector bundle over $B$ whose fiber at each point $p$ consists of all the linear maps from. $V_{p}$ to $W_{p}$. Define Iso( $V, W$ ) to be the
subset of $\operatorname{Hom}(V, W)$ whose fiber at each point consists of all the isomorphisms from $V_{p}$ to $W_{p}$. (This is like looking at the complement of the zero section of a line bundle.) Iso( $V, W$ ) inherits a topology from $\operatorname{Hom}(V, W)$, and is a fiber bundle with fiber $G L(n, \mathbb{R})$. An isomorphism between $V$ and $W$ is simply a section of Iso( $V, W$ ).

Let $f: Y \times I \rightarrow X$ be a homotopy between $f_{0}$ and $f_{1}$, and let $\pi: Y \times I \rightarrow Y$ be the projection. Suppose for some $t_{0}^{\&}$ in $I, f_{t_{0}}^{-1} E$ is isomorphic to some vector bundle $F$ on $Y$. We will show that for all $t$ near $t_{0}$, $f_{i}^{-1} E \simeq F$. By the compactness of the unit interval $I$ it will then follow that $f_{t}^{-1} E \simeq F$ for all $t$ in $I$.

Over $Y \times I$ there are two pullback bundles, $f^{-1} E$ and $\pi^{-1} F$. Since $f_{t 0}^{-1} E \simeq F$, $\operatorname{Iso}\left(f^{-1} E, \pi^{-1} F\right)$ has a section over $Y \times t_{0}$, which a priori is also a section of $\operatorname{Hom}\left(f^{-1} E, \pi^{-1} F\right)$. Since $Y$ is compact, $Y \times t_{0}$ may be covered with a finite number of trivializing open sets for $\operatorname{Hom}\left(f^{-1} E, \pi^{-1} F\right)$ (see Figure 6.1). As the fiber of $\operatorname{Hom}\left(f^{-1} E, \pi^{-1} F\right)$ are Euclidean spaces, the section over $Y \times t_{0}$ may be extended to a section of $\operatorname{Hom}\left(f^{-1} E, \pi^{-1} F\right)$ over the union of these open sets. Now any linear map near an isomorphism remains an isomorphism; thus we can extend the given section of Iso $\left(f^{-1} E, \pi^{-1} F\right)$ to a strip containing $Y \times t_{0}$. This proves that $f_{1}^{-1} E \simeq F$ for $t$ near $t_{0}$. We now cover $Y \times I$ with a finite number of such strips. Hence $f_{0}^{-1} E \simeq F \simeq f_{1}^{-1} E$.

Figure 6.1

Remark. If $Y$ is not compact, we may not be able to find a strip of constant width over which Iso $\left(f^{-1} E, \pi^{-1} F\right)$ has a section; for example the strip may look like Figure 6.2.

But the same argument can be refined to give the theorem for $Y$ a paracompact space. See, for instance, Husemoller [1, Theorem 4.7, p. 29]. Recall that $Y$ is said to be paracompact if every open cover $\mathfrak{U}$ of $Y$ has a locally finite open refinement $\mathfrak{U}^{\prime}$, that is, every point in $Y$ has a neighborhood which meets only finitely many open sets in $\mathfrak{u}^{\prime}$. A compact space or a discrete space are clearly paracompact. By a theorem of A. H. Stone, so is every metric space (Dugundji [1, p. 186]). More importantly for us, every manifold is paracompact (Spivak [1, Ch. 2, Th. 13, p. 66]). Thus the homotopy

Figure 6.2
property of vector bundles (Theorem 6.8) actually holds over any manifold $Y$, compact or not.

Corollary 6.9. A vector bundle over a contractible manifold is trivial.
Proof. Let $E$ be a vector bundle over $M$ and let $f$ and $g$ be maps

$$
M \underset{g}{\stackrel{f}{\rightleftarrows}} \text { point }
$$

such that $g \circ f$ is homotopic to the identity $1_{M}$. By the homotopy property of vector bundles

$$
E \simeq(g \circ f)^{-1} E \simeq f^{-1}\left(g^{-1} E\right)
$$

Since $g^{-1} E$ is a vector bundle on a point, it is trivial, hence so is $f^{-1}\left(g^{-1} E\right)$.

So for a contractible manifold $M, \operatorname{Vect}_{k}(M)$ is a single point.
Remark. Although all the results in this subsection are stated in the differentiable category of manifolds and smooth maps, the corresponding statements with "manifold" replaced by "space" also hold in the continuous category of topological spaces and continuous maps, the only exception being Corollary 6.9, in which the space should be assumed paracompact.

Exercise 6.10. Compute $\operatorname{Vect}_{k}\left(S^{1}\right)$.

## Compact Cohomology of a Vector Bundle

The Poincaré lemmas

$$
\begin{aligned}
& H^{*}\left(M \times \mathbb{R}^{n}\right)=H^{*}(M) \\
& H_{c}^{*}\left(M \times \mathbb{R}^{\prime \prime}\right)=H_{c}^{*-n}(M)
\end{aligned}
$$

may be viewed as results on the cqhomology of the trivial bundle $M \times \mathbb{R}^{n}$ over $M$. More generally let $E$ be a vector bundle of rank $n$ over $M$. The zero section of $E, s: x \mapsto(x, 0)$, embeds $M$ diffeomorphically in $E$. Since $M \times\{0\}$ is a deformation retract of $E$, it follows from the homotopy axiom for de Rham cohomology (Corollary 4.1.2.2) that

$$
H^{*}(E) \simeq H^{*}(M)
$$

For cohomology with compact support one may suspect that

$$
\begin{equation*}
H_{c}^{*}(E) \simeq H_{c}^{*-n}(M) \tag{6.11}
\end{equation*}
$$

This is in general not true; the open Möbius strip, considered as a vector bundle over $S^{1}$, provides a counterexample, since the compact cohomology of the Möbius strip is identically zero (Exercise 4.8). However, if $E$ and $M$ are orientable manifolds of finite type, then formula (6.11) holds. The proof is based on Poincaré duality, as follows. Let $m$ be the dimension of $M$. Then

$$
\begin{aligned}
H_{c}^{*}(E) & \simeq\left(H^{m+n-*}(E)\right)^{*} \quad \text { by Poincare duality on } E \\
& \simeq\left(H^{m+n-*}(M)\right)^{*} \text { by the homotopy axiom for de Rham cohomology } \\
& \simeq H_{c}^{*-n}(M) \quad \text { by Poincare duality on } M .
\end{aligned}
$$

Lemma 6.12. An orientable vector bundle $E$ over an orientable manifold $M$ is an orientable manifold.

Proof. This follows from the fact that if $\left\{\left(U_{a}, \psi_{a}\right)\right\}$ is an oriented atlas for $M$ with transition functions $h_{\alpha \beta}=\psi_{\alpha} \circ \psi_{\beta}^{-1}$ and

$$
\phi_{a}:\left.E\right|_{U_{a}} \approx U_{\alpha} \times \mathbb{R}^{n}
$$

is a local trivialization for $E$ with transition functions $g_{\alpha \beta}$, then the composition

$$
\left.E\right|_{U_{a}} \nrightarrow U_{a} \times \mathbb{R}^{n} \nrightarrow \mathbb{R}^{m} \times \mathbb{R}^{n}
$$

' gives an atlas for $E$. The typical transition function of this atlas,

$$
\left(\psi_{a} \times 1\right) \circ \phi_{\alpha} \phi_{\beta}^{-1} \circ\left(\psi_{\beta}^{-1} \times 1\right): \mathbb{R}^{m} \times \mathbb{R}^{n} \rightarrow \mathbb{R}^{m} \times \mathbb{R}^{n}
$$

sends $(x, y)$ to $\left(h_{a \beta}(x), g_{a \beta}\left(\psi_{a}^{-1}(x)\right) y\right)$ and has Jacobian matrix

$$
\left(\begin{array}{cc}
D\left(h_{\alpha \beta}\right) & *  \tag{6.12.1}\\
0 & g_{\alpha \beta}\left(\psi_{a}^{-1}(x)\right)
\end{array}\right)
$$

where $D\left(h_{a \beta}\right)$ is the Jacobian matrix of $h_{a \beta}$. The determinant of the matrix (6.12.1) is clearly positive.

Thus,
Proposition 6.13. If $\pi: E \rightarrow M$ is an orientable vector bundle and $M$ is orientable, then $H_{c}^{*}(E) \simeq H_{c}^{*-"}(M)$.

Remark 6.13.1. Actually the orientability assumption on $M$ is superfluous. See Exercise 6.20.

Remark 6.13.2. Let $M$ be an oriented manifold with oriented atlas $\left\{\left(U_{a}\right.\right.$, $\left.\left.\psi_{a}\right)\right\}$ and $\pi: E \rightarrow M$ an oriented vector bundle over $M$ with orientation $\left\{\left(U_{a}, \phi_{a}\right)\right\}$. Then $E$ can be made into an oriented manifold with orientation given by the oriented atlas

$$
\left\{\pi^{-1}\left(U_{a}\right),\left(\psi_{a} \times 1\right) \circ \phi_{a}: \pi^{-1}\left(U_{a}\right) \rightarrow U_{a} \times \mathbb{R}^{n} \rightarrow \mathbb{R}^{m} \times \mathbb{R}^{n}\right\}
$$

This is called the local product orientation on $E$.

## Compact Vertical Cohomology and Integration along the Fiber

As mentioned earlier, for vector bundles there is a third kind of cohomology. Instead of $\Omega_{c}^{*}(E)$, the complex of forms with compact support, we consider $\Omega_{c v}^{*}(E)$, the complex of forms with compact support in the vertical direction; in other words, a form in $\Omega_{c u}^{*}(E)$ need not have compact support in $E$ but its restriction to each fiber has compact support. The cohomology of this complex, denoted $H_{c v}^{*}(E)$, is called the cohomology of $E$ with compact support in the vertical direction, or compact vertical cohomology.

Let $E$ be oriented as a rank $n$ vector bundic. The formulas in (4.4) extend to this situation to give integration along the fiber, $\boldsymbol{R}_{*}: \Omega_{c v}^{*}(E) \rightarrow \Omega^{*-n}(M)$, as follows. First consider the case of a trivial bundle $E=M \times R^{n}$. Let $t_{1}, \ldots, t_{n}$ be the coordinates on the fiber $\mathbb{R}^{n}$. A form on $E$ is a real linear - combination of two types of forms: the type (I) forms are those which do not contain as a factor the $n$-form $d t_{1} \ldots d t_{n}$ and the type (II) forms are those which do. The map $\pi_{*}$ is defined by
(I) $\left(\pi^{*} \phi\right) f\left(x, t_{1}, \ldots, t_{n}\right) d t_{t_{1}} \ldots d t_{i_{6}} \mapsto 0, \quad r<n$
(II) $\left(\pi^{*} \phi\right) f\left(x, t_{1}, \ldots, t_{n}\right) d t_{1} \ldots d t_{n} \mapsto \phi \int_{R^{*}} f\left(x, t_{1}, \ldots, t_{n}\right) d t_{1} \ldots d t_{n}$,
where $f$ has compact support for each fixed $x$ in $M$ and $\phi$ is a form on $M$. Next suppose $E$ is an arbitrary oriented vector bundle, with oriented trivialization $\left\{\left(U_{a}, \phi_{a}\right)\right\}_{a \in 1}$. Let $x_{1}, \ldots, x_{m}$ and $y_{1}, \ldots, y_{m}$ be the coordinate functions on $U_{a}$ and $U_{\beta}$, and $t_{1}, \ldots, t_{n}, u_{1}, \ldots, u_{n}$ the fiber coordinates on $\left.E\right|_{U_{a}}$ and $\left.E\right|_{U_{k}}$ given by $\phi_{a}$ and $\phi_{\beta}$ respectively. Because $\left\{\left(U_{a}, \phi_{a}\right)\right\}$ is an oriented trivialization for $E$, the two sets of fiber coordinates $t_{1}, \ldots, t_{n}$ and $u_{1} \ldots, u_{n}$ are related by an element of $G L^{+}(n, R)$ at each point of $U_{n} \cap U_{B}$. Again a form $\omega$ in $\Omega_{c v}^{*}(E)$ is locally of type (I) or (II). The map $\pi_{*}$ is defined to be zero on type (I) forms. To define $\pi_{,}$on type (II) forms, write $\omega_{\text {e }}$ for $\left.\omega\right|_{\text {R-1 }}\left(U_{e}\right)$. Then

$$
\omega_{s}=\left(\pi^{*} \phi\right) f\left(x_{1}, \ldots, x_{m}, t_{1}, \ldots, t_{n}\right) d t_{1} \ldots d t_{n}
$$

and

$$
\omega_{p}=\left(\pi^{*} \tau\right) g\left(y_{1}, \ldots, y_{m}, u_{1}, \ldots, u_{n}\right) d u_{1} \ldots d u_{n}
$$

Define

$$
\pi_{*} \omega_{*}=\phi \int_{\mathbb{R}_{n}} f(x, t) d t_{1} \ldots d t_{n}
$$

Exercise 6.14. Show that if $E$ is an oriented vector bundle, then $\pi_{*} \omega_{\alpha}=$ $\pi_{*} \omega_{\beta}$. Hence $\left\{\pi_{*} \omega_{a}\right\}_{a \in 1}$ piece together to give a global form $\pi_{*} \omega$ on $M$. Furthermore, this definition is independent of the choice of the oriented trivialization for $E$.

Proposition 6.14.1. Integration along the fiber $\pi_{*}$ commutes with exterior differentiation $d$.

Proof. Let $\left\{\left(U_{\alpha}, \phi_{a}\right)\right\}$ be a trivialization for ${ }^{-} E,\left\{\rho_{\alpha}\right\}$ a partition of unity subordinate to $\left\{U_{\alpha}\right\}$, and $\omega$ a form in $\Omega_{c v}^{*}(E)$. Since $\omega=\sum \rho_{\alpha} \omega$, and both $\pi_{*}$ and $d$ are linear, it suffices to prove the proposition for $\rho_{a} \omega$, that is, $\pi_{*} d\left(\rho_{\alpha} \omega\right)=d \pi_{*}\left(\rho_{a} \omega\right)$. Thus from the outset we may assume $E$ to be the product bundle $M \times \mathbb{R}^{n}$. If $\omega=\left(\pi^{*} \phi\right) f(x, t) d t_{1} \ldots d t_{n}$ is a type (II) form,

$$
\begin{aligned}
d \pi_{*} \omega & =d\left(\phi \int f(x, t) d t_{1} \ldots d t_{n}\right) \\
& =(d \phi) \int f(x, t) d t_{1} \ldots d t_{n}+(-1)^{\operatorname{deg} \phi} \phi \sum_{i} d x_{i} \int \frac{\partial f}{\partial x_{i}}(x, t) d t_{1} \ldots d t_{n}
\end{aligned}
$$

and

$$
\begin{aligned}
\pi_{*} d \omega & =\pi_{*}\left(\left(\pi^{*} d \phi\right) f d t_{1} \ldots d t_{n}+(-1)^{\operatorname{deg} \phi} \pi^{*} \phi \sum \frac{\partial f}{\partial x_{i}} d x_{i} d t_{1} \ldots d t_{n}\right) \\
& =(d \phi) \int f d t_{1} \ldots d t_{n}+(-1)^{\text {deg } \phi} \sum_{i} \phi d x_{i} \int \frac{\partial f}{\partial x_{i}} d t_{1} \ldots d t_{n} .
\end{aligned}
$$

So $d \pi_{*} \omega=\pi_{*} d \omega$ for a type (II) form. Next let $\omega=\left(\pi^{*} \phi\right) f(x, t) d t_{i_{1}} \ldots d t_{i_{6}}$, $r<n$, be a type (I) form. Then

$$
d \pi_{*} \omega=0
$$

and

$$
\begin{aligned}
\pi_{*} d \omega & =(-1)^{\operatorname{deg} \phi} \sum_{i} \pi_{*}\left(\left(\pi^{*} \phi\right) \frac{\partial j}{\partial t_{i}}(x, t) d t_{i} d t_{i_{1}} \ldots d t_{i_{0}}\right) \\
& =0 \quad \text { if } \quad d t_{i} d t_{i_{1}} \ldots d t_{j} \neq \pm d t_{1} \ldots d t_{i} \cdot
\end{aligned}
$$

If $d t_{i} d t_{i_{1}} \ldots d t_{i_{h}}= \pm d t_{1} \ldots d t_{n}$, then $\int \partial f / \partial t_{i}(x, t) d t_{i} d t_{i_{1}} \ldots d t_{i_{1}}$ is again 0 : because $f$ has compact support,

$$
\int_{-\infty}^{\infty} \frac{\partial f}{\partial t_{i}}(x, t) d t_{i}=f(\ldots, \infty, \ldots)-f(\ldots,-\infty, \ldots)=0
$$

Note that integration along the fiber, $\pi_{*}: \Omega^{*}(E) \rightarrow \Omega^{*-n}(M)$ lowers the degree of a form by the fiber dimension.

Proposition 6.15 (Projection Formula). (a) Let $\pi: E \rightarrow M$ be an oriented rank $n$ vector bundle, $\tau$ a form on $M$ and $\omega$ a form on $E$ with compact support along the fiber. Then

$$
\pi_{*}\left(\left(\pi^{*} \tau\right) \cdot \omega\right)=\tau \cdot \pi_{*} \omega
$$

(b) Suppqse in addition that $M$ is oriented of dimension $m, \omega \in \boldsymbol{\Omega}_{c v}^{q}(E)$, and $\tau \in \Omega_{c}^{m+n-q}(M)$. Then with the local product orientation on $E$

$$
\int_{E}\left(\pi^{*} \tau\right) \wedge \omega=\int_{M} \tau \wedge \pi_{*} \omega
$$

Proof. (a) Since two forms are the same if and only if they are the same locally, we may assume that $E$ is the product bundle $M \times \mathbb{R}^{n}$. If $\omega$ is a form of type (I), say $\omega=\pi^{*} \phi \cdot f(x, t) d t_{i_{1}} \ldots d t_{i_{r}}$, where $r<n$, then

$$
\left.\pi_{*}\left(\left(\pi^{*} \tau\right) \cdot \omega\right)^{*}=\pi_{*}\left(\pi^{*}(\tau \phi) \cdot f(x, t) d t_{i_{1}} \ldots d t_{i}\right)\right)=0=\tau \cdot \pi_{*} \omega
$$

If $\omega$ is a form of type (II), say $\omega=\pi^{*} \phi \cdot f(x, t) d t_{1} \ldots d t_{n}$, then

$$
\pi_{*}\left(\left(\pi^{*} \tau\right) \cdot \omega\right)=\tau \phi \int_{R^{*}} f(x, t) d t_{1} \ldots d t_{n}=\tau \cdot \pi_{*} \omega .
$$

(b) Let $\left\{\left(U_{\alpha}, \phi_{\alpha}\right)\right\}_{a \in J}$ be an oriented trivialization for $E$ and $\left\{\rho_{\alpha}\right\}_{a \in j}$ a partition of unity subordinate to $\left\{U_{\alpha}\right\}$. Writing $\omega=\sum \rho_{\alpha} \omega$, where $\rho_{\alpha} \omega$ has support in $U_{k}$, we have

$$
\int_{E}\left(\pi^{*} \tau\right) \wedge \dot{\omega}=\sum_{a} \int_{\varepsilon_{v_{k}}}\left(\pi^{*} \tau\right) \wedge\left(\rho_{a} \omega\right)
$$

and

$$
\int_{M} \tau \wedge \pi_{*} \omega=\sum_{a} \int_{U_{a}} \tau \wedge \pi_{\#}\left(\rho_{\alpha} \omega\right) .
$$

'Here $\tau \wedge \pi_{*}\left(\rho_{\alpha} \omega\right)$ has compact support because its support is a closed subset of the compact set Supp $\tau$; similarly, $\left(\pi^{*} \tau\right) \wedge\left(\rho_{a} \omega\right)$ also has compact support. Therefore, it is enough to prove the proposition for $M=U_{q}$ and $E$ trivial. The rest of the proof proceeds as in (a).

The proof of the Poincaré lemma for compact supports (4.7) carries over verbatim to give

Proposition 6.16 (Poincaré Lemma for Compact Vertical Supports). Inte-: gration along the fiber defines an isomorphism

$$
\pi_{*}: H_{c v}^{*}\left(M \times \mathbf{R}^{v}\right) \rightarrow H^{*-\pi}(M)
$$

This is a special case of
Theorem 6.17 (Thom Isomorphism). If the vector bundle $\pi: E \rightarrow M$ over a manifold $M$ of finite type is orientable, then

$$
H_{c v}^{*}(E) \simeq H^{*-n}(M)
$$

where $n$ is the rank of $E$.

Proof. Let $U$ and $V$ be open subsets of $M$. Using a partition of unity from the base $M$ we see that

$$
0 \rightarrow \Omega_{v v}^{*}\left(\left.E\right|_{U \cup v}\right) \rightarrow \Omega_{v v}^{*}\left(\left.E\right|_{v}\right) \oplus \Omega_{c v}^{*}\left(\left.E\right|_{v}\right) \rightarrow \Omega_{c v}^{*}\left(\left.E\right|_{U \cap v}\right) \rightarrow 0
$$

is exact, as in (2.3). So we have the diagram of Mayer-Vietoris sequences

The commutativity of this diagram is trivial for the first two squares; we will check that of the third. Recalling from (2.5) the explicit formula for the coboundary operator $d^{*}$, we have by the projection formula (6.15)

$$
\pi_{*} d^{*} \omega=\pi_{*}\left(\left(\pi^{*} d \rho_{U}\right) \cdot \omega\right)=\left(d \rho_{v}\right) \cdot \pi_{*} \omega=d^{*} \pi_{*} \omega .
$$

So the diagram in question is commutative.
By (6.9) if $U$ is diffeomorphic to $\mathbb{R}^{n}$, then $\left.E\right|_{U}$ is trivial, so that in this case the Thom isomorphism reduces to the Poincaré lemma for compact vertical supports (6.16). Hence in the diagram above, $\pi_{*}$ is an isomorphism for contractible open sets. By the Five Lemma if the Thom isomorphism holds for $U, V$, and $U \cap V$, then it holds for $U \cup V$. The proof now proceeds by induction on the cardinality of a good cover for the base, as in the proof of Poincare duality. This gives the Thom isomorphism for any manifold $M$ having a finite good cover.

Remark 6.17.1. Although the proof above works only for a manifold of finite type, the theorem is actually true for any base space. We will reprove the theorem for an arbitrary manifold in (12.2.2).

Under the Thom isomorphism $\mathscr{T}: H^{*}(M) \simeq H_{c v}^{*+n}(E)$, the image of 1 in $H^{0}(M)$ determines a cohomology class $\Phi$ in $H_{c v}^{n}(E)$, called the Thom class of the oriented vector bundle $E$. Because $\pi_{*} \Phi=1$, by the projection formula (6.15)

$$
\pi_{*}\left(\pi^{*} \omega \wedge \Phi\right)=\omega \wedge \pi_{*} \Phi=\omega
$$

So the Thom isomorphism, which is inverse to $\pi_{*}$, is given by

$$
\mathscr{I}(\quad)=\pi^{*}() \wedge \Phi .
$$

Proposition 618. The Thom class $\Phi$ on a rank $n$ oriented vector bundle $E$ can be uniquely characterized as the cohomology class in $H_{c v}^{n}(E)$ which restricts to the generator of $H_{c}^{\prime \prime}(F)$ on each fiber $F$.

Proof. Since $\pi_{*} \Phi=1,\left.\Phi\right|_{\text {fiber }}$ is a bump form on the fiber with total integral 1. Conversely if $\Phi^{\prime}$ in $H_{c v}^{\prime}(E)$ restricts to a generator on each fiber, then

$$
\pi_{*}\left(\left(\pi^{*} \omega\right) \wedge \Phi^{\prime}\right)=\omega \wedge \pi_{*} \Phi^{\prime}=\omega
$$

Hence $\pi^{*}() \wedge \Phi^{\prime}$ must be the Thom isomorphism $\mathscr{T}$ and $\Phi^{\prime}=\mathscr{T}(1)$ is the Thom class.

Proposition 6.19. If $E$ and $F$ are two oriented vector bundles over a manifold $M$, and $\pi_{1}$ and $\pi_{2}$ are the projections

then the Thom class of $E \oplus F$ is $\Phi(E \oplus F)=\pi_{1}^{*} \Phi(E) \wedge \pi_{2}^{*} \Phi(F)$.
Proof. Let $m=\operatorname{rank} E$ and $n=\operatorname{rank} F$. Then $\pi_{i}^{*} \Phi(E) \wedge \pi_{2}^{*} \Phi(F)$ is a class in $H_{c v}^{m+n}(E \oplus F)$ whose restriction to each fiber is a generator of the compact cohomology of the fiber, since the isomorphism

$$
H_{c}^{m+m}\left(\mathbb{R}^{m} \times \mathbb{R}^{n}\right) \simeq H_{c}^{m}\left(\mathbb{R}^{m}\right) \otimes H_{c}^{m}\left(\mathbb{R}^{m}\right)
$$

is given by the wedge product of the generators.
Exercise 6.20. Using a Mayer-Vietoris argument as in the proof of the Thom isomorphism (Theorem 6.17), show that if $\pi: E \rightarrow M$ is an orientable rank $n$ bundle, then

$$
H_{c}^{*}(E) \simeq H_{c}^{{ }^{-}-m}(M) .
$$

Note that this is Proposition 6.13 with the orientability assumption on $M$ removed.

## Poincaré Duality and the Thom Class

Let $S$ be a closed oriented submanifold of dimension $k$ in an oriented manifold $M$ of dimension $n$. Recall from (5.13) that the Poincare dual of $S$ is the cohomology class of the closed $(n-k)$-form $\eta_{s}$ characterized by the property

$$
\begin{equation*}
\int_{S} \omega=\int_{M} \omega \wedge \eta_{S} \tag{6.21}
\end{equation*}
$$

for any closed $k$-form with compact support on $M$. In this section we will explain how the Poincaré dual of a submanifold relates to the Thom class of a bundle (Proposition 6.24). To this end we first introduce the notion of a tubular neighborhood of $S$ in $M$; this is, by definition an open neighborhood of $S$ in $M$ diffeomorphic to a vector bundle of rank $n-k$ over $S$. Now a sequence of vector bundles over $M$,

$$
0 \rightarrow E \rightarrow E^{\prime} \rightarrow E^{\prime \prime} \rightarrow 0
$$

is said to be exact if at each point $p$ in $M$, the sequence of vector spaces

$$
0 \rightarrow E_{p} \rightarrow E_{p}^{\prime} \rightarrow E_{p}^{*} \rightarrow 0
$$

is exact, where $E_{p}$ is the fiber of $E$ at $p$. If $S$ is a submanifold in $M$, the normal bundle $N=N_{S / M}$ of $S$ in $M$ is the vector bundle on $S$ defined by the exact sequence

$$
\begin{equation*}
\left.0 \rightarrow T_{S} \rightarrow T_{M}^{\prime}\right|_{S} \rightarrow N \rightarrow 0 \tag{6.22}
\end{equation*}
$$

where $\left.T_{M}\right|_{S}$ is the restriction of the tangent bundle of $M$ to $S$. The tubular neighborhood theorem states that every submanifold $S$ in $M$ has a tubular neighborhood $T$, and that in fact $T$ is diffeomorphic to the normal bundle of $S$ in $M$ (see Spivak [1, p. 465] or Guillemin and Pollack [1, p. 76]). For example, if $S$ is a curve in $\mathbb{R}^{3}$, then a tubular neighborhood of $S$ may be constructed using the metric in $\mathbb{R}^{3}$ by attaching to each point of $S$ an open disc of radius one perpendicular to $S$ at the center. The union of all these discs is a tubular neighborhood of $S$ (Figure 6.3(a)).

Figure 6.3
In general if $A$ and $B$ are two oriented vęctor bundles with oriented trivializations $\left\{\left(U_{a}, \phi_{a}\right)\right\}$ and $\left\{\left(U_{a}, \psi_{a}\right)\right\}$, respectively, then the direct sum. orientation on $A \oplus B$ is given by the oriented trivialization $\left\{\left(U_{\alpha}, \phi_{\alpha} \oplus \psi_{a}\right)\right\}$. Returning to our submanifold $S$ in $M$, we let $j: T \hookrightarrow M$ be the inclusion of a tubular neighborhood $T$ of $S$ in $M$ (see Figure 6.3(b)). Since $S$ and $M$ are orientable, the normal bundle $N_{S}$, being the quotient of $\left.T_{M}\right|_{S}$ by $T_{S}$, is also orientable. By convention it is ociented in such a way that

$$
N_{S} \oplus T_{S}=\left.T_{M}\right|_{S}
$$

has the direct sum orientation. So the Thom isomorphism theorem applies to the normal bundle $T=N_{s}$ over $S$ and we have the sequence of maps

$$
H^{*}(S) \stackrel{\hat{\rightrightarrows}}{\rightrightarrows} H_{c v}^{*+n-k}(T) \xrightarrow{j_{*}} H^{*+n-k}(M)
$$

where $\Phi$ is the Thom class of the tube $T$ and $j_{*}$ is extension by 0 ; here $j_{*}$ is defined because we are only concerned with forms on the tubular neighborhood $T$ which vanish near the boundary of $T$. We claim that the Poincare
dual of $S$ is the Thom class of the normal bundle of $S$; more precisely

$$
\begin{equation*}
\eta_{S}=j_{*}(\Phi \wedge 1)=j_{*} \Phi \quad \text { in } H^{n-k}(M) \tag{6.23}
\end{equation*}
$$

To prove this we merely have to show that $j_{*} \Phi$ satisfies the defining property (5.13) of the Poincare dual $\eta_{s}$. Let $\omega$ be any closed $k$-form with compact support on $M$, and $i: S \rightarrow T$ the inclusion, regarded as the zero section of the bundle $\pi: T \rightarrow S$. Since $\pi$ is a deformation retraction of $T$ onto $S, \pi^{*}$ and $i^{*}$ are inverse isomorphisms in cohomology. Therefore on the level of forms, $\omega$ and $\pi^{*} i^{*} \omega$ differ by an exact form: $\omega=\pi^{*} i^{*} \omega+d \tau$.

$$
\begin{aligned}
& \int_{M} \omega \wedge j_{\boldsymbol{*}} \Phi \\
& =\int_{T} \omega \wedge \Phi \quad \text { because } j_{*} \Phi \text { has support in } T \\
& =\int_{T}\left(\pi^{* i} i^{*} \omega+d \tau\right) \wedge \Phi \\
& =\int_{T}\left(\pi^{*} i^{*} \omega\right) \wedge \Phi \quad \text { since } \int_{T}(d \tau) \wedge \Phi=\int_{T} d(\tau \wedge \Phi)=0 \text { by Stokes } \\
& \text { theorem } \\
& =\int_{S} i^{*} \omega \wedge \pi_{*} \Phi \quad \text { by the projection formula (6.15) } \\
& =\int_{S} i^{*} \omega \quad \text { because } \pi_{*} \Phi=1 .
\end{aligned}
$$

This concludes the proof of the claim. Note that if $S$ is compact, then its Poincaré dual $\eta_{s}=j_{*} \Phi$ has compact support.

Conversely, suppose $E$ is an oriented vector bundle over an oriented manifold $M$. Then $M$ is diffeomorphically embedded as the zero section in $E$ and there is an exact sequence

$$
\left.0 \rightarrow T_{M} \rightarrow\left(T_{E}\right)\right|_{M} \rightarrow E \rightarrow 0
$$

i. $\mathrm{e}_{\mathrm{m}}$ the normal bundle of $M$ in $E$ is $E$ itself. By (6.23), the Poincare dual of $M$ in $\dot{E}$ is the Thom class of $E$. In summary,

Proposition 6.24. (a) The Poincaré dual of a closed oriented submanifold $S$ th an oriented manifold $M$ and the Thom class of the normal bundle of $S$ can be represented by the same forms.
(b) The Thom class of an oriented vector bundle. $\pi: E \rightarrow M$ over an oriented manifold $M$ and the Poincaré dual of the zero section of $E$ can be represented by the same form.

Because the normal bundle of the submanifold $S$ in $M$ is diffeomorphic to any tubular neighborhood of $S$, we have the following proposition.
Proposition 6.25 (Localization Principle). The support of the Poincaré dual of a submanifold $S$ can be shrunk into any given tubular neighborhood of $S$.

Figure 6.4
Example 6.26.
(a) The Poincare dual of a point $p$ in $M$.

A tubular neighborhood $T$ of $p$ is simply an open ball around $p$ (Figure 6.4). A generator of $H_{c v}^{n}(T)$ is a bump $n$-form with total integral 1 . So the Poincaré dual of a point is a bump $n$-form on $M$. The form need not have support at $p$ since all bump $n$-forms on a connected manifold are cohomologous.
(b) The Poincaré dual of $M$.

Here the tubular neighborhood $T$ is $M$ itself, and $H_{c v}^{*}(T)=H^{*}(M)$. So the Poincare dual of $M$ is the constant function 1 .
(c) The Poincaré dual of a circle on a torus.

Figure 6.5

The Poincare dual is a bump 1-form with support in a tubular neighborhood of the circle and with total integral 1 on each fiber of the tubular neighborhood (Figure 6.5). In the usual representation of the torus as a square, if the circle is a vertical segment, then its Poincare dual is $\rho(x) d x$ where $\rho$ is a bump function with total integral 1 (Figure 6.6).

Using the explicit construction of the Poincare dual $\eta_{s}=j_{*} \Phi$ as the Thom class of the normal bundle, we now prove two basic properties of Poincaré duality. Two submanifolds $R$ and $S$ in $M$ are said to intersect transuersally if and only if

$$
\begin{equation*}
T_{x} R+T_{x} S=T_{x} M \tag{6.27}
\end{equation*}
$$

Figure 6.6
at all points $x$ in the intersection $R \cap S$ (Guillemin and Pollack [1, pp. 27-32]). For such a transversal intersection the codimension in $M$ is addi-, tive:

$$
\begin{equation*}
\operatorname{codim} R \cap S=\operatorname{codim} R+\operatorname{codim} S \tag{6.28}
\end{equation*}
$$

This implies that the normal bundle of $R \cap S$ in $M$ is

$$
\begin{equation*}
N_{R \cap S}=N_{R} \oplus N_{S} \tag{6.29}
\end{equation*}
$$

Assume $M$ to be an oriented manifold, and $R$ and $S$ to be closed oriented submanifolds. Denoting the Thom class of an oriented vector bundle $E$ by $\Phi(E)$, we have by (6.19)

$$
\begin{equation*}
\Phi\left(N_{R \cap S}\right)=\Phi\left(N_{R} \oplus N_{S}\right)=\Phi\left(N_{R}\right) \wedge \Phi\left(N_{S}\right) . \tag{6.30}
\end{equation*}
$$

Therefore,

$$
\begin{equation*}
\eta_{R \cap S}=\eta_{R} \wedge \eta_{s} ; \tag{6.31}
\end{equation*}
$$

i.e., under Poincaré duality the transversal intersection of closed oriented submanifolds corresponds to the wedge product of forms.

If $f: M^{\prime} \rightarrow M$ is an orientation-preserving map of oriented manifolds, $T$ is a tubular neighborhood of the closed oriented submanifold $S$ in $M$, and $f\left(M^{\prime}\right)$ is transversal to $S$ and $T$, then $f^{-1} T$ is a tubular neighborhood of $f^{-1} S$ in $M^{\prime}$. From the commutative diagram

we see that if $\omega$ is the cohomology class on $M$ representing the submanifold $S$ in $M$, then $f^{*} \omega$ is the cohomology class on $M^{\prime}$ representing $f^{-1}(S)$, i.c., under Poincare duality the induced map on cohomology corresponds to the pre-image in geometry, i.e., $\eta_{f-1(s)}=\int^{\boldsymbol{*}} \eta_{s}$.

## The Global Angular Form, the Euler Class, and the Thom Class

In this subsection we will construct explicitly the Thom class of an oriented rank 2 vector bundle $\pi: E \rightarrow M$, using such data as a partition of unity on $M$ and the transition functions of $E$. The higher-rank case is similar but more involved, and will be taken up in (11.11) and (12.3). The construction is best understood as the vector-bundle analogue of the procedure for going from a generator of $H^{n-1}\left(S^{n-1}\right)=H^{n-1}\left(\mathbb{R}^{n}-\{0\}\right)$ to a generator of $H_{c}^{n}\left(\mathbb{R}^{n}\right)$. So let us first try to understand the situation in $\mathbb{R}^{n}$.

We will call a top form on an oriented manifold $M$ positive if it is in the orientation class of $M$. The standard orientation on the unit sphere $S^{n-1}$ in $\mathbb{R}^{n}$ is by convention the following one: if $\sigma$ is a generator of $H^{n-1}\left(S^{n-1}\right)$ and $\pi: \mathbb{R}^{n}-\{0\} \rightarrow S^{n-1}$ is a deformation retraction, then $\sigma$ is positive on $S^{n-1}$ if and only if $d r \cdot \pi^{*} \sigma$ is positive on $\mathbb{R}^{n}-\{0\}$.

Exercise 6.32. (a) Show that if $\theta$ is the standard angle function on $\mathbb{R}^{2}$, measured in the counterclockwise direction, then $d \theta$ is positive on the circle $S^{1}$.
(b) Show that if $\phi$ and $\theta$ are the spherical coordinates on $\mathbb{R}^{\mathbf{3}}$ as in Figure 6.7; then $d \phi \wedge d \theta$ is positive on the 2 -sphere $S^{2}$.

Figure 6.7

- Let $\sigma$ be the positive generator of $H^{n-1}\left(S^{n-1}\right)$ and $\psi=\pi^{*} \sigma$ the corresponding generator of $H^{n-1}\left(\mathbb{R}^{n}-\{0\}\right) ; \psi$ is called the angular form on $\mathbf{R}^{n}-\{0\}$. If $\rho(r)$ is the function of the radius shown in Figure 6.8, then $d \rho=\rho^{\prime}(r) d r$ is a bump form on $\mathbf{R}^{1}$ with total integral 1 (Figure 6.9). Therefore (d $\rho$ ) $\psi \psi$ is a compactly supported form on $\mathbb{R}^{n}$ with total integral 1 , i.e., ( $d \rho$ ) $\psi$ is the generator of $H_{c}^{\prime \prime}\left(\mathbb{R}^{\prime \prime}\right)$. Note that because $\psi$ is closed, we can write

$$
\begin{equation*}
(d \rho) \cdot \psi=d(\rho \cdot \psi) \tag{6.33}
\end{equation*}
$$

Figure 6.8

Now let $E$ be an oriented rank $n$ vector bundle over $M$, and $E^{0}$ the complement of the zero section in $E$. Endow $E$ with a Riemannian structure as in (6.4) so that the radius function $r$ makes sense on $E$. We begin our construction of the Thom class by finding a global form $\psi$ on $E^{0}$ whose restriction to each fiber is the angular form on $R^{n}-\{0\} . \psi$ is called the global angular form. Once we have the angular form $\psi$, it is then easy to check that $\Phi=d(\rho \cdot \psi)$ is the Thom class.

Now suppose the rank of $E$ is 2 , and $\left\{U_{a}\right\}$ is an open cover of $M$. Since $E$ has a Riemannian structure, over each $U_{a}$ we can choose an orthonormal frame. This defines on $\left.E^{0}\right|_{u_{a}}$ polar coordinates $r_{a}$ and $\hat{\theta}_{\alpha}$; if $x_{1}, \ldots, x_{a}$ are coordinates on $U_{a}$, then $\pi^{*} x_{1}, \ldots, \pi^{*} x_{n}, r_{\alpha}, \theta_{a}$ are coordinates on $E^{0} \mid U_{\alpha}$ On the overlap $U_{\alpha} \cap U_{\beta}$, the radii $r_{\alpha}$ and $r_{\beta}$ are equal but the angular coordinates $\theta_{\alpha}$ and $\theta_{\beta}$ differ by a rotation. By the orientability of $E$, it makes sense to speak of the "counterclockwise direction" in each fiber. This allows

Figure 6.9
us to define unambiguously $\varphi_{a \beta}$ as the angle of rotation in the counterclockwise direction from the $\alpha$-coordinate system to the $\beta$-coordinate system:

$$
\begin{equation*}
\theta_{\beta}=\theta_{\alpha}+\pi^{*} \varphi_{\alpha \beta}, 0 \leq \varphi_{a \beta}<2 \pi . \tag{6.34}
\end{equation*}
$$

Although rotating from $\alpha$ to $\beta$ and then from $\beta$ to $\gamma$ is the same as rotating from $\alpha$ to $\gamma$, it is not true that $\varphi_{a \beta}+\varphi_{\beta \gamma}-\varphi_{a \gamma}=0$; indeed all that one can say is

$$
\varphi_{a \beta}+\varphi_{\beta y}-\varphi_{\alpha \gamma} \in 2 \pi \mathbb{Z}
$$

Aside. To each triple intersection we can associate an integer

$$
\begin{equation*}
\varepsilon_{\alpha \beta \gamma}=\frac{1}{2 \pi}\left(\varphi_{\alpha \beta}-\varphi_{\alpha y}+\varphi_{\beta \gamma}\right) . \tag{6.35}
\end{equation*}
$$

The collection of integers $\left\{\varepsilon_{\alpha \beta y}\right\}$ measures the extent to which $\left\{\varphi_{\alpha \beta}\right\}$ fails to be a cocyle. We will give another interpretation of $\left\{\varepsilon_{a \beta \gamma}\right\}$ in Section 11.

Unlike the functions $\left\{\varphi_{a \beta}\right\}$, the 1 -forms $\left\{d \varphi_{a \beta}\right\}$ satisfy the cocycle condition.

Exercise 6.36. There exist 1-forms $\xi_{\alpha}$ on $U_{\alpha}$ such that

$$
\frac{1}{2 \pi} d \varphi_{a \beta}=\xi_{\beta}-\xi_{\alpha}
$$

[Hint: Take $\xi_{s}=\sum_{\gamma} \rho_{\gamma} d \varphi_{a y}$, where $\left\{\rho_{\gamma}\right\}$ is a partition of unity subordinate to $\left\{\boldsymbol{U}_{y}\right\}$.]

It foHows from Exercise 6.36 that $d \xi_{\alpha}=d \xi_{\beta}$ on $U_{\alpha} \cap U_{\beta}$. Hence the $d \xi_{\alpha}$ piece together to give a global 2 -form $e$ on $M$. This giobal form $e$ is clearly closed. It is not necessarily exact since the $\xi_{a}$ do not usually piece together to give a global 1 -form. The cohomology class of $e$ in $H^{2}(M)$ is called the Euler class of the oriented vector bundle $E$. We sometimes write e $e(E)$ instead of $e$.

Claim. The cohomology class of $e$ is independent of the choice of $\xi$ in our construction.

Proof of Claim. If $\left\{\overline{\bar{s}}_{\alpha}\right\}$ is a different choice of 1 -forms such that

$$
\frac{1}{2 \pi} d \varphi_{a \beta}=\bar{\xi}_{\beta}-\xi_{a}=\xi_{\beta}-\xi_{a}
$$

then

$$
\bar{\xi}_{A}-\xi_{\beta}=\bar{\xi}_{a}-\xi_{a}=\xi
$$

is a global form. So $d \bar{\xi}_{a}$ and $d \xi_{a}$ differ by an exact global form.

By (6.34) and (6.36), on $\left.E^{0}\right|_{v_{s} \cap v_{f}}$,

$$
\begin{equation*}
\frac{d \theta_{\alpha}}{2 \pi}-\pi^{*} \xi_{\alpha}=\frac{d \theta_{\beta}}{2 \pi}-\pi^{*} \xi_{\beta} . \tag{6.36.1}
\end{equation*}
$$

These forms then piece together to give a global 1-form $\psi$ on $E^{0}$, the global angular form, whose restriction to each fiber is the angular form $(1 / 2 \pi) d \theta$, i.e., if $t_{p}: \mathbb{R}^{2} \rightarrow E$ is the orthogonal inclusion of a fiber over $p$, then $t_{p} * \psi=$ $(1 / 2 \pi) d \theta$. The global angular form is not closed:

$$
d \psi=d\left(\frac{d \theta_{\alpha}}{2 \pi}-\pi^{*} \xi_{\alpha}\right)=-\pi^{*} d \xi_{\varepsilon}=-\pi^{*} d \xi_{\beta} .
$$

Therefore,

$$
\begin{equation*}
d \psi=-\pi^{*} e \tag{6.37}
\end{equation*}
$$

When $E$ is a product, $\psi$ could be taken to be the pullback of $(1 / 2 \pi) d \theta$ under the projection $E^{0}=M \times\left(\mathbf{R}^{2}-0\right) \rightarrow R^{2}-0$. In this case $\psi$ is closed and $e$ is 0 . The Euler class is in this sense a measure of the twisting of the oriented vector bundle $E$.

The Euler class of an oriented rank 2 vector bundle may be given in terms of the transition functions, as follows. Let $g_{a p}: U_{a} \cap U_{\beta} \rightarrow \mathrm{SO}(2)$ be the transition functions of $E$. By identifying $S O(2)$ with the unit circle in the complex plane via $\left(\begin{array}{cc}\cos \theta & -\sin ^{\sin \theta} \theta \\ \cos \theta \\ \cos \end{array}\right)=e^{i \theta}, g_{a f}$ may be thought of as complexvalued functions. In this context the angle from the $\beta$-coordinate system to the $\alpha$-coordinate system is $(1 / i) \log g_{a \beta}$. Thus

$$
\theta_{\alpha}-\theta_{\beta}=\pi^{*}(1 / i) \log g_{\alpha f},
$$

and

$$
\pi^{*} d \varphi_{a \beta}=-\pi^{*}(1 / i) \log g_{a \rho}
$$

Since the projection $\pi$ has maximal rank, $\pi^{*}$ is injective, so that

$$
d \varphi_{a f}=-(1 / t) \log g_{a f} .
$$

Let $\left\{\rho_{y}\right\}$ be a partition of unity subordinate to $\left\{U_{y}\right\}$. Then

$$
\frac{1}{2 \pi} d \varphi_{a \beta}=\xi_{g}-\xi_{a}
$$

where

$$
\begin{equation*}
\xi_{\alpha}=\frac{1}{2 \pi} \sum_{\gamma} \rho_{\gamma} d \varphi_{\gamma \mu}=-\frac{1}{2 \pi i} \sum_{\gamma} \rho_{\gamma} d \log g_{\gamma a} \tag{6.37.1}
\end{equation*}
$$

Therefore,

$$
\begin{equation*}
e(E)=-\frac{1}{2 \pi i} \sum_{\gamma} d\left(\rho_{\gamma} d \cdot \log g_{\gamma a}\right) \quad \text { on } U_{a} \tag{6.38}
\end{equation*}
$$

Proposition 6.39. The Euler class is functorial, i.e., if $f: N \rightarrow M$ is a $C^{\infty}$ map and $E$ is a rank 2 oriented vector bundle over $M$, then

$$
e\left(f^{-1} E\right)=f^{*} e(E)
$$

Proof. Since the transition functions of $f^{-1} E$ are $f^{*} g_{\alpha \beta}$, the proposition is an immediate consequence of (6.38).

We claim that just as in the untwisted case (6.33), the Thom class is the cohomology class of

$$
\begin{equation*}
\Phi=d(\rho(r) \cdot \psi)=d \rho(r) \cdot \psi-\rho(r) \pi^{*} e \tag{6.40}
\end{equation*}
$$

Although $\psi$ is defined only outside the zero section of $E$, the form $\Phi$ is a global form on $E$ since $d \rho \equiv 0$ near the zero section. $\Phi$ has the following properties:
(a) compact support in the vertical direction;
(b) closed: $d \Phi=-d \rho(r) \cdot d \psi-d \rho(r) \pi^{*} e=0$;
(c) restriction to each fiber has total integral 1 :

$$
\pi_{*} l_{p}^{*} \Phi=\int_{0}^{\infty} \int_{0}^{2 \pi} d \rho(r) \cdot \frac{d \theta}{2 \pi}=\rho(\infty)-\rho(0)=1
$$

where $t_{p}: E_{p} \rightarrow E$ is the inclusion of the fiber $E_{p}$ into $E$;
(d) the cohomology class of $\Phi$ is independent of the choice of $\rho(r)$. Suppose $\bar{\rho}(r)$ is another function of $r$ which is -1 near 0 and 0 near infinity, and which defines $\overline{\boldsymbol{\Phi}}$. Then

$$
\Phi-\bar{\Phi}=d((\rho(r)-\bar{\rho}(r))-\ddot{\psi})
$$

where $(\rho(r)-\bar{\rho}(r)) \cdot \psi$ is a global form on $E$ because $\rho(r)-\bar{\rho}(r)$ vanishes near the zero section.

Therefore $\Phi$ indeed defines the Thom class. Furthermore, if $s: M \rightarrow E$ is the zero section of $E$, then

$$
s^{*} \Phi=d(\rho(0)) \cdot s^{*} \psi-\rho(0) s^{*} \pi^{*} e=e
$$

This proves
Proposition 6.41. The pullback of the Thom class to $M$ by the zero section is the Euler class.

Let $\left\{U_{a}\right\}$ be a trivializing cover for $E,\left\{\rho_{a}\right\}$ a partition of unity subordinate to $\left\{U_{a}\right\}$, and $g_{a} f$ the transition functions for $E$. Since

$$
\begin{aligned}
\psi & =\frac{d \theta_{\alpha}}{2 \pi}-\pi^{*} d \xi_{a} \\
& =\frac{d \theta_{a}}{2 \pi}+\frac{1}{2 \pi i} \pi^{*} \sum_{\gamma} \rho_{\gamma} d \log g_{\gamma \alpha} .
\end{aligned}
$$

(cf. (6.36.1) and (6.37.1)), we have by (6.40),

$$
\begin{equation*}
\Phi=d\left(\rho(r) \frac{d \theta_{a}}{2 \pi}\right)+\frac{1}{2 \pi i} d\left(\rho(r) \pi^{*} \sum_{\gamma} \rho_{\gamma} d \log g_{\gamma \alpha}\right. \tag{6.42}
\end{equation*}
$$

This is the explicit formula for the Thom class.
Exercise 6.43. Let $\pi: E \rightarrow M$ be an oriented rank 2 bundle. As we saw in the proof of the Thom isomorphism, wedging with the Thom class is an isomorphism $\wedge \Phi: H^{*}(M) \simeq H_{c v}^{*+2}(E)$. Therefore every cohomology class on $E$ is the wedge product of $\Phi$ with the pullback of a cohomology class on $M$. Find the class $u$ on $M$ such that

$$
\Phi^{2}=\Phi \wedge \pi^{*} u \text { in } H_{c v}^{*}(E)
$$

Exercise 6.44. The complex projective space $\mathbb{C P}^{\boldsymbol{m}}$ is the space of all lines through the origin in $\mathbb{C}^{n+1}$, topologized as the quotient of $\mathbb{C}^{n+1}$ by the equivalence relation

$$
z \sim \lambda z \text { for } z \in \mathbb{C}^{n+1}, \lambda \text { a nonzero complex number. }
$$

Let $z_{0}, \ldots, z_{n}$ be the complex coordinates on $\mathbb{C}^{n+1}$. These give a set of homogeneous coordinates $\left[z_{0}, \ldots, z_{n}\right]$ on $\mathbb{C} P^{n}$, determined up to multiplication by a nonzero complex number $\lambda$. Define $U_{i}$ to be the open subset of $\mathbb{C} P^{n}$ given by $z_{i} \neq 0 .\left\{U_{0}, \ldots, U_{n}\right\}$ is called the standard open cover of $\mathbb{C} P^{*}$.
(a) Show that $\mathbb{C} P^{n}$ is a manifold.
(b) Find the transition functions of the normal bundle $N_{\mathbb{C P 1 / C P}}$ relative to the standard open cover of $\mathbb{C} P^{1}$.

Example 6.44.1. (The Euler class of the normal bundle of $\mathbb{C} P^{1}$ in $\mathbb{C} P^{2}$ ). Let $N=N_{\mathbb{C} 1, \mathbb{C} P^{2}}$ be the normal bundle of $\mathbb{C} P^{1}$ in $\mathbb{C} P^{2}$. Since $\mathbb{C} P^{1}$ is a compact oriented manifold of real dimension 2, its top-dimensional cohomology is $H^{2}\left(\mathbb{C} P^{1}\right)=\mathbb{R}$. We will find the Euler class $e(N)$ as a multiple of the generator in $H^{2}\left(\mathbb{C} P^{1}\right)$.

By Exercise 6.44 the transition function of $N$ relative to the standard open cover is $g_{01}=z_{0} / z_{1}$ at the point $\left[z_{0}, z_{1}\right]$. Let $z=z_{0} / z_{1}$ be the coordinate of $U_{1}$, which we identify with the complex plane $\mathbb{C}$. By (6.38) the Euler
class $e(N)$ on $U_{1}$ is given by

$$
\begin{aligned}
e(N) & =-\frac{1}{2 \pi i} d \rho_{0} d \log g_{01} \\
& =-\frac{1}{2 \pi i} d \rho_{0} d \log z
\end{aligned}
$$

where $\rho_{0}$ is 1 in a neighborhood of the origin, and 0 in a neighborhood of infinity.

Fix a circle $C$ in the complex plane with so large a radius that Supp $\rho_{0}$ is contained inside $C$. Let $A_{r}$ be the annulus centered at the origin whose outer circle is $C$ and whose inner circle $B_{r}$ has radius $r$ (Figure 6.10). Note that as the boundary of $A_{r}$, the circle $C$ is oriented counterclockwise while $B$ is oriented clockwise.

Figure 6.10

Now

$$
\int_{C P i} e(N)=-\frac{1}{2 \pi i} \int_{C} d \rho_{0} d \log z
$$

and

$$
\begin{aligned}
\int_{C} d\left(\rho_{0} d z / z\right) & =\lim _{r \rightarrow 0} \int_{A_{r}} d\left(\rho_{0} d z / z\right) \\
& =\lim _{r \rightarrow 0} \int_{C} \rho_{0} d z / z+\int_{B_{r}} \rho_{0} d z / z \quad \text { by Stokes' theorem } \\
& =\lim _{r \rightarrow 0} \int_{B_{r}} d z / z \\
& =-2 \pi i
\end{aligned}
$$

where the minus sign is due to the clockwise orientation on $B_{r}$. Therefore,

$$
\int_{C P 1} e(N)=-\frac{1}{2 \pi i}(-2 \pi i)=1 .
$$

Exercise 6.45. On the complex projective space CP ${ }^{\text {n }}$ there is a tautological line bundle $S$, called the universal subbundle; it is the subbundle of the product bundle $C P^{m} \times \mathbb{C}^{\infty+1}$ given by

$$
S=\{(\ell, z) \mid z \in \ell\} .
$$

Above each point $\ell$ in $\mathbb{C P}{ }^{n}$, the fiber of $S$ is the line represented by $\ell$. Find the transition functions of the universal subbundle $S$ of $C P^{1}$ relative to the standard open cover and compute its Euler class.

Exercise 6.46. Let $S^{n}$ be the unit sphere in $\mathbb{R}^{n+1}$ and $i$ the antipodal map on $\boldsymbol{S}^{n}$ :

$$
i:\left(x_{1}, \ldots, x_{n+1}\right) \rightarrow\left(-x_{1}, \ldots,-x_{n+1}\right) .
$$

The real projective space $\mathbb{R} P^{n}$ is the quotient of $S^{n}$ by the equivalence relation

$$
x \sim i(x), \quad \text { for } \quad x \in \mathbb{R}^{n+1}
$$

(a) An invariant form on $S^{n}$ is a form $\omega$ such that $i^{*} \omega=\omega$. The vector space of invariant forms on $S^{n}$, denoted $\Omega^{*}\left(S^{*}\right)^{\prime}$, is a differential complex, and so the invariant cohomology $H^{*}\left(S^{\prime \prime}\right)^{\prime}$ of $S^{n}$ is defined. Show that $H^{*}\left(\mathbb{R} P^{\prime \prime}\right) \simeq H^{*}\left(S^{n}\right)^{J}$.
(b) Show that the natural map $H^{*}\left(S^{\prime \prime}\right)^{\lambda} \rightarrow H^{*}\left(S^{\eta}\right)$ is injective. [Hint : If $\omega$ is an invariant form and $\omega=d \tau$ for some form $\tau$ on $S^{\mathbf{n}}$, then $\omega=$ $\left.d\left(\tau+i^{*} \tau\right) / 2.\right]$
(c) Give $S^{n}$ its standard orientation (p. 70). Show that the antipodal map $i: S^{\boldsymbol{n}} \rightarrow S^{n}$ is orientation-preserving for $n$ odd and orientation-reversing for $n$ even. Hence, if $[\sigma]$ is a generator of $H^{\prime \prime}\left(S^{n}\right)$, then $[\sigma]$ is an invariant cohomology class if and only if $n$ is odd.
(d) Show that the de Rham cohomology of $\mathbb{R} P^{n}$ is

$$
H^{q}\left(\mathbb{R} P^{n}\right)= \begin{cases}\mathbb{R} & \text { for } q=0 \\ 0 & \text { for } 0<q<n \\ \mathbb{R} & \text { for } q=n \text { odd } \\ 0 & \text { for } q=n \text { even }\end{cases}
$$

## Relative de Rham Theory

The Thom class of an oriented vector bundle may be viewed as a relative cohomology class, which we now define. Let $f: S \rightarrow M$ be a map between two manifolds. Define a complex $\Omega^{*}(f)=\oplus_{q \geqslant 0} \Omega^{q}(f)$ by

$$
\begin{aligned}
\Omega^{q}(f) & =\Omega^{q}(M) \oplus \Omega^{q-1}(S), \\
d(\omega, \theta) & =\left(d \omega, f^{*} \omega-d \theta\right)
\end{aligned}
$$

It is easily verified that $d^{2}=0$. Note that a cohomology class in $\Omega^{*}(f)$ is represented by a closed form $\omega$ on $M$ which becomes exact when pulled back to $S$.

By definition we have the exact sequence

$$
0 \rightarrow \Omega^{q^{-1}}(S) \xrightarrow{a} \Omega^{q}(f) \xrightarrow{\beta} \Omega^{q}(M) \longrightarrow 0
$$

with the obvious maps $\alpha$ and $\beta: \alpha(\theta)=(0, \theta)$ and $\beta(\omega, \theta)=\omega$. Clearly $\beta$ is a chain map but $\alpha$ is not quite a chain map; in fact it anticommutes with $d$ $\alpha d=-d \alpha$. In any case there is still a long exact sequence in cohomol $r$

$$
\begin{equation*}
\cdots \rightarrow H^{q-1}(S) \xrightarrow{a^{\bullet}} H^{q}(f) \xrightarrow{\mathscr{F}_{\infty}} H^{q}(M) \xrightarrow{\dot{b}^{\bullet}} H^{q}(S) \rightarrow \cdots \tag{6.47}
\end{equation*}
$$

Claim 6.48. $\delta^{*}=f^{*}$.
Proof of Claim. Consider the diagram

$$
\begin{array}{ccc}
0 \rightarrow \Omega^{q}(S) & \rightarrow \Omega^{q+1}(f) \rightarrow \Omega^{q+1}(M) \rightarrow 0 \\
d \uparrow & d \uparrow & d \uparrow \\
0 \rightarrow \Omega^{q-1}(S) \rightarrow & \Omega^{q}(f) \rightarrow & \Omega^{q}(M) \rightarrow 0 \\
& \psi & \omega \\
& (\omega, \theta) & \omega
\end{array}
$$

Let $\omega \in \Omega^{q}(M)$ be a closed form and $(\omega, \theta)$ any element of $\Omega^{q}(f)$ which maps to $\omega$. Then $d(\omega, \theta)=\left(0, f^{*} \omega-d \theta\right)$. So $\partial^{*}[\omega]=\left[f^{*} \omega-d \theta\right]=\left[f^{*} \omega\right]$.

Combining (6.47) and (6.48) we have
Proposition 6.49. Let $f: S \rightarrow M$ be a differentiable map between two mainifolds. Then there is an exact sequence

$$
\cdots \rightarrow H^{q}(f) \xrightarrow{\beta^{\bullet}} H^{q}(M) \xrightarrow{f^{\bullet}} H^{q}(S) \xrightarrow{\alpha} H^{q+1}(f) \rightarrow \cdots .
$$

Exercise 6.50. If $f, g: S \rightarrow M$ are homotopic maps, show that $H^{*}(f)$ and $H^{*}(g)$ are isomorphic algebras.

If $S$ is a submanifold of $M$ and $i: S \rightarrow M$ is the inclusion map, we define the relative de Rham cohomology $H^{q}(M, S)$ to be $H^{q}(i)$.

We now turn to the Thom class. Recall that if $\pi: E \rightarrow M$ is a rank $n$ oriented vector bundle and $E^{0}$ is the complement of the zero section, then there is a globai angular form $\psi$ on $E^{0}$ such that $d \psi=-\pi^{*} e$, where $e$ represents the Euler class of $E$ (6.37). Furthermore, if $s: M \rightarrow E$ is the zero section, then $e=s^{*} \Phi$ (Proposition 6.41). Hence, $(s \circ \pi)^{*} \Phi=-d \psi$, where $s \circ \pi: E^{0} \rightarrow E$. This shows that $(\Phi,-\psi)$ is closed in the complex $\Omega^{*}(s \circ \pi)$ and ${ }^{\circ} \mathrm{s}$ represents a class in $H^{\pi}(s \circ \pi)$. Since the map $s \circ \pi: E^{0} \rightarrow E$ is clearly homotopic to the inclusion $i: E^{0} \rightarrow E$, by Exercise $6.50, H^{n}(s \circ \pi)=H^{n}(i)$. Hence, $(\Phi,-\psi)$ represents a class in the relative cohomology $H^{n}\left(E, E^{0}\right)$.

## $\S 7$ The Nonorientable Case

Since the integral of a differential form on $\mathbb{R}^{n}$ is not invariant under the whole group of diffeomorphisms of $\mathbb{R}^{n}$, but only under the subgroup of orientation-preserving diffeomorphisms, a differential form cannot be integrated over a nonorientable manifold. However, by modifying a differential form we obtain something called a density, which can be integrated over any manifold, orientable or not. This will give us a version of Poincare duality for nonorientable manifolds and of the Thom isomorphism for nonorientable vector bundles.

## The Twisted de Rham Complex .

- Let $M$ be a manifold and $E$ a vector space. The space of differential forms on $M$ with values in $E$, denoted $\Omega^{*}(M, E)$, is by definition the vector space spanned by $\omega \otimes v$, where $\omega \in \Omega^{*}(M), v \in E$, and the tensor product is over $\mathbb{R}$. This space can be made naturally into a differential complex if we let the differential be

$$
d(\omega \otimes v)=(d \omega) \otimes v
$$

So the cohomology $H^{*}(M, E)$ is defined. Indeed, if $E$ is a vector space of dimension $n$, then $H^{*}(M, E)$ is isomorphic to $n$ copies of $H_{D_{R}}(M)$.

Now let $E$ be a vector bundle. We define the space of $E$-valued $q$-forms, $\Omega^{q}(M, E)$, to be the global sections of the vector bundle ( $\left.\Lambda^{q} T_{M}^{*}\right) \otimes E$. Locally such a $q$-form can be written as $\sum \omega_{i} \otimes e_{i}$, where $\omega_{i}$ are $q$-forms and $e_{i}$ are sections of $E$ over some open set $U$ in $M$, and the tensor product is over the $C^{\infty}$ functions on $U$. For these vector-valued differential forms, no natural extension of the de Rham complex is possible, unless one is first given a way of differentiating the sections of $E$.

Suppose the vector bundle $E$ has a trivialization $\left\{\left(U_{\alpha}, \phi_{\alpha}\right)\right\}$ relative to which the transition functions are locally constant. Such a vector bundle is called a flat vector bundle and the trivialization a locally constant trivialization. For a flat vector bundle $E$ a differential operator on $\Omega^{*}(M, E)$ may be defined as follows. Let $e_{\alpha}^{1}, \ldots, e_{\alpha}^{n}$ be the sections of $E$ over $U_{\alpha}$ corresponding to the standard basis under the trivialization $\phi_{a}:\left.E\right|_{U_{a}} \rightarrow$ $U_{a} \times \mathbf{R}^{n}$. We declare these to be the standard locally constant sections, i.e., $d e_{a}^{i}=0$. Over $U_{a}$ an $E$-valued $q$-form $s$ in $\Omega^{a}(M, E)$ can be written as $\sum \omega_{i} \otimes e_{\alpha}^{i}$, where the $\omega_{i}$ are $q$-forms over $U_{a}$. We define the exterior derivative $d s$ over $U_{\varepsilon}$ by linearity and the Leibnitz rule:

$$
d\left(\sum \omega_{i} \otimes e_{\alpha}^{i}\right)=\sum\left(d \omega_{i}\right) \otimes e_{\alpha}^{i}
$$

It is easy to show that, because the transition functions of $E$ relative to $\left\{\left(U_{\alpha}, \phi_{\alpha}\right)\right\}$ are locally constant, this definition of exterior differentiation is independent of the open sets $U_{\alpha}$. More precisely, on the overlap $U_{\alpha} \cap U_{\beta}$, if

$$
s=\sum \omega_{i} \otimes e_{a}^{i}=\sum \tau_{j} \otimes e_{\beta}^{j}
$$

and $e_{e}^{i}=\sum c_{i j} e_{j}^{j}$, where the $c_{i j}$ are locally constant functions, then

$$
\tau_{j}=\sum c_{i j} \omega_{i}
$$

and

$$
\begin{aligned}
d\left(\sum \tau_{j} \otimes e_{\beta}^{j}\right) & =\sum\left(d \tau_{j}\right) \otimes e_{\beta}^{j} \\
& =\sum\left(c_{i j} d \omega_{i}\right) \otimes e_{\beta}^{j} \\
& =\sum\left(d \omega_{i}\right) \otimes e_{\alpha}^{i} \\
& =d\left(\sum \omega_{i} \otimes e_{\alpha}^{i}\right)
\end{aligned}
$$

Hence $d s$ is globally defined and is an element of $\Omega^{+1}(M, E)$. Because $d^{2}$ is clearly zero, $\Omega^{*}(M, E)$ is a differential complex and the cohomology $H^{*}(M, E)$ makes sense. As defined, $d$ very definitely depends on the trivialization $\left\{\left(U_{a}, \phi_{a}\right)\right\}$, for it is through the trivialization that the locally constant sections are given. Hence, $d, \Omega^{*}(M, E)$, and $H^{*}(M, E)$ are more properiy denoted as $d_{\phi}, \Omega_{\phi}^{*}(M, E)$, and $H_{\phi}^{*}(M, E)$.

Example 7.1 (Two trivializations of a vector bundle $E$ which give rise to distinct cohomology groups $H^{*}(M, E)$ ).

Let $M$ be the circle $S^{1}$ and $E$ the trivial line bundie $S^{1} \times \mathbf{R}^{1}$ over the circle. If $E$ is given the usual constant trivialization $\phi$ :

$$
\phi(x, r)=r \quad \text { for } \quad x \in S^{1} \quad \text { and } \quad r \in \mathbb{R}^{1}
$$

then the cohomology $H_{\phi}^{0}\left(S^{1}, E\right)=\mathbb{R}$.
However, we can define another locally constant trivialization $\psi$ for $E$ as follows. Cover $S^{1}$ with two open sets $U$ and $V$ as indicated in Figure 7.1.

Figure 7.1

Let $\rho(x)$ be the real-valued function on $V$ whose graph is as in Figure 7.2. The trivialization $\psi$ is given by

$$
\psi(x, r)= \begin{cases}r & \text { for } x \in U, r \in \mathbb{R}^{1} \\ \rho(x) r & \text { for } x \in V, r \in \mathbb{R}^{1}\end{cases}
$$

The standard locally constant sections over $U$ and $V$ are $e_{U}(x)=(x, 1)$ and $e_{\nu}(x)=(x, 1 / \rho(x))$ respectively. Relative to the trivialization $\psi$, the cohomology $H_{\psi}^{0}\left(S^{1}, E\right)=0$, since the locally constant sections over $U$ and $V$ do not piece together to form a global section (except for the zero section).

It is natural to ask : to what extent is the twisted cohomology $H_{\$}^{*}(M, E)$ independent of the trivialization $\phi$ for $E$ ?

Figure 7.2
Proposition 7.2. The twisted cohomology is invariant under the refinement of open covers. More precisely, let $\left\{\left(U_{a}, \phi_{a}\right)\right\}_{\alpha \in I}$ be a locally constant trivialization for E. Suppose $\left\{V_{\beta}\right\}_{\beta \in J}$ is a refinement of $\left\{U_{\alpha}\right\}_{\alpha \in 1}$ and the coordinates maps $\psi_{\beta}$ on $V_{B} \subset U_{a}$ are the restrictions of $\phi_{a}$. Then the two twisted complexes $\Omega_{\phi}^{*}(M, E)$ and $\Omega_{\psi}^{*}(M, E)$ are identical and so are their cohomology :

$$
H_{\phi}^{*}(M, E)=H_{\psi}^{*}(M, E) .
$$

Proof. Since the definition of the differential operator on a twisted complex is local, and $\phi$ and $\psi$ agree on the open cover $\left\{V_{\beta}\right\}$, we have $d_{\phi}=d_{\psi}$. Therefore the two complexes $\Omega_{\phi}^{*}(M, E)$ and $\Omega_{\psi}^{*}(M, E)$ are identical.

Still assuming $E$ to be a flat vector bundle, suppose $\left\{\left(U_{a}, \phi_{a}\right)\right\}$ and $\left\{\left(U_{\alpha}, \psi_{\alpha}\right)\right\}$ are two locally constant trivializations which differ by a locally constant comparison 0 -cochain, i.e., if $e_{\alpha}^{i}$ and $f_{\alpha}^{j}$ are the standard locally constant sections over $U_{a}$ relative to the trivializations $\phi$ and $\psi$ respectively, then

$$
e_{\alpha}^{i}=\sum_{j} a_{a}^{i j} f_{\alpha}^{j}
$$

for some locally constant function

$$
a_{\alpha}=\left(a_{a}^{i}\right): U_{\alpha} \rightarrow \mathrm{GL}(n, \mathbb{R}) .
$$

In this case there is an obvious isomorphism

$$
F: \Omega(M, E) \rightarrow \Omega q(M, E)
$$

given by

$$
e_{a}^{i} \mapsto \sum_{j} a_{a}^{l} f_{a}^{j}
$$

It is easily checked that the diagram

commutes. Hence $F$ induces an isomorphism in cohomology. Next, suppose we are given two locally constant trivializations $\left\{\left(U_{\alpha}, \phi_{\alpha}\right)\right\}$ and $\left\{\left(V_{\beta}, \psi_{\beta}\right)\right\}$ for $E$, with possibly different open covers. By taking a common refinement, which does not affect the twisted cohomology (Proposition 7.2), we may assume that the two open covers are identical. The discussion above therefore proves the following.

Proposition 7.3. (a) Let $E$ be a flat vector bundle oyer $M$, and $\left\{\left(U_{a}, \phi_{a}\right)\right\}$ and $\left\{\left(V_{\beta}, \psi_{\beta}\right)\right\}$ two locally constant trivializations for E. Suppose after a common refinement the two trivializations differ by a locally constant comparison 0 cochain. Then there are isomorphisms

$$
\Omega_{\phi}^{*}(M, E) \simeq \Omega_{\psi}^{*}(M, E)
$$

and

$$
H_{\phi}^{*}(M, E) \simeq H_{\psi}^{*}(M, E) .
$$

This proposition may also be stated in terms of the transition functions for $E$.

Proposition 7.3. (b) Let $E$ be a flat vector bundle of rank $n$ and $\left\{g_{\alpha \beta}\right\}$ and $\left\{h_{\alpha \beta}\right\}$ the transition functions for E relative to two locally constant trivializations $\phi$ and $\psi$ with the same open cover. If there exist locally constant functions.

$$
\lambda_{\alpha}: U_{\varepsilon} \rightarrow \mathrm{GL}(n, \mathbf{R})
$$

such that

$$
g_{\alpha \beta}=\lambda_{\alpha} h_{\alpha \beta} \lambda_{\beta}^{-1}
$$

then there are isomorphisms as in 7.3(a).
Proposition 7.4. If $E$ is a trivial rank $n$ vector bundle over a manifold $M$, with $\phi$ a trivialization of $E$ given by $n$ global sections, then

$$
H_{\phi}^{*}(M, E)=H^{*}\left(M, \mathbb{P}^{m}\right)=\bigoplus_{i=1}^{n} H^{*}(M)
$$

Proof. Let $e_{1}, \ldots, e_{n}$ be the $n$ global sections corresponding to the standard basis of $R^{*}$. Then every element in $\Omega^{*}(M, E)$ can be written uniquely as $\sum \omega_{i} \otimes e_{i}$, where $\omega_{i} \in \Omega^{*}(M)$ and the tensor product is over the $C^{\infty}$ functions on $M$. The map

$$
\sum \omega_{i} \otimes e_{i} \mapsto\left(\omega_{1}, \ldots, \omega_{n}\right)
$$

gives an isomorphism of the complexes $\Omega^{*}(M, E)$ and $\Omega^{*}\left(M, \mathbb{R}^{n}\right)$.
Now let $\left\{\left(U_{\alpha}, \phi_{\alpha}\right)\right\}$ be a coordinate open cover for the manifold $M$, with transition functions $\boldsymbol{g}_{a \beta}=\phi_{a} \circ \phi_{\beta}^{-1}$. Define the sign function on $\mathbf{R}^{1}$ to be

$$
\operatorname{sgn}(x)=\left\{\begin{aligned}
+1 & \text { for } x \text { positive } \\
0 & \text { for } x=0 \\
-1 & \text { for } x \text { negative }
\end{aligned}\right.
$$

The orientation bundle of $M$ is the line bundle $L$ on $M$ given by transition functions sgn $J\left(g_{\alpha \beta}\right)$, where $J\left(g_{\alpha \beta}\right)$ is the Jacobian determinant of the matrixof partial derivatives of $g_{\alpha \beta}$. It follows directly from the definition that $M$ is orientable if and only if its orientation bundle is trivial.

Relative to the atlasis $\left\{\left(U_{\alpha}, \phi_{\alpha}\right)\right\}$ for $M$ with transition functions $g_{\alpha \beta}$, the orientation bundle is by definition the quotient

$$
\left(U_{\alpha} \times \mathbb{R}^{1}\right) /(x, v) \sim\left(x, \operatorname{sgn} J\left(g_{\alpha \beta}(x)\right) v\right)
$$

where $(x, v) \in U_{a} \times \mathbb{R}^{2}$ and $\left(x, \operatorname{sgn} J\left(g_{a f}(x)\right) v\right) \in U_{p} \times \mathbb{R}^{1}$. By construction there is a natural trivialization $\phi^{\prime}$ on $L$,

$$
\phi_{a}^{\prime}:\left.L\right|_{U_{s}} \simeq U_{a} \times \mathbb{R}^{1}
$$

which we call the trivialization induced from the atlas $\left\{\left(U_{\alpha}, \phi_{a}\right)\right\}$ on $M$. Because $\operatorname{sgn} J\left(g_{\alpha \beta}\right)$ are locally constant functions on $M$, the locally constant sections of $L$ relative to this trivialization are the equivalence classes of $\left\{(x, v) \mid x \in U_{a}\right\}$ for $v$ fixed in $\mathbb{R}^{\mathbf{1}}$.

Proposition 7.5. If $\phi^{\prime}$ and $\psi^{\prime}$ are two trivializations for $L$ induced from two atlases $\phi$ and $\psi$ on $M$, then the two twisted complexes $\Omega_{\phi}^{*}(M, L)$ and $\Omega^{*}(M$, $L)$ are isomorphic and so are their cohomology $H_{\$}^{*}(M, L)$ and $H^{*}(M, L)$.

Proof. By going to a common refinement we may assume that the two atlases $\phi$ and $\psi$ have the same open cover. Thus on each $U_{s}$ there are two sets of coordinate functions, $\phi_{a}$ and $\psi_{a}$ (Figure 7.3.).

Figure 7.3

The transition functions $g_{\alpha \beta}$ and $h_{\alpha \beta}$ for the two atlases $\phi$ and $\psi$ respectively are related by

$$
\begin{aligned}
g_{\alpha \beta}(x) & =\left.\phi_{\alpha} \phi_{\beta}^{-1}\right|_{(x) \times R_{1}} \\
& =\left.\phi_{\alpha} \psi_{a}^{-1} \psi_{\alpha} \psi_{\beta}^{-1} \psi_{\beta} \phi_{\beta}^{-1}\right|_{(x) \times \mathbb{R} 1} \\
& =\mu_{\alpha}(x) h_{\alpha \beta}(x) \mu_{\beta}(x),
\end{aligned}
$$

where $\mu_{\alpha}: U_{\alpha} \cap U_{\beta} \rightarrow \mathrm{GL}(1, \mathbb{R})$ is the function

$$
\mu_{\alpha}(x)=\left.\phi_{a} \psi_{a}^{-1}\right|_{\left\{x \mid \times R_{1}\right.} .
$$

It follows that

$$
\operatorname{sgn} J\left(g_{a \beta}\right)=\operatorname{sgn} J\left(\mu_{\alpha}\right) \cdot \operatorname{sgn} J\left(h_{\alpha \beta}\right) \cdot \operatorname{sgn} J\left(\mu_{\beta}\right)^{-1} .
$$

Since sgn $J\left(\mu_{a}\right)= \pm 1$, by Proposition 7.3(b)

$$
\Omega_{\phi}^{*}(M, L) \simeq \Omega^{\#}(M, L) .
$$

We define the twisted de Rham complex $\Omega^{*}(M, L)$ and the twisted de Rham cohomology $H^{*}(M, L)$ to be $\Omega_{\phi}^{*}(M, L)$ and $H^{*}(M, L)$ for any trivialization $\phi^{\prime}$ on $L$ which is induced from $M$. Similarly one also has the twisted de Rham cohomology with compact support, $H_{c}^{*}(M, L)$.

Remark. If a trivialization $\psi$ on $L$ is not induced from $M$, then $H_{\psi}^{*}(M, L)$ may not be equal to the twisted de Rham cohomology $H^{*}(M, L)$.

The following statement is an immediate consequence of Proposition 7.4 and the triviality of $L$ on an orientable manifold.

Proposition 7.6. On an orientable manifold $M$ the twisted de Rham cohorpology $H^{*}(M, L)$ is the same as the ordinary de Rham cohomology.

Integration of Densities, Poincaré Duality, and the Thom Isomorphism

Let $M$ be a manifold of dimension $n$ with coordinate open cover $\left\{\left(U_{n}, \phi_{j}\right)\right\}$ and transition functions $g_{a p}$. A dersity on $M$ is an element of $\Omega^{\prime \prime}(M, L)$, or equivalently, a section of the density bundle ( $\left.\Lambda^{n} T T^{\prime}\right) \otimes L$. One may think of a density as a top-dimensional differential form twisted by the orientation bundle. Since the transition function for the exterior power $\Lambda^{\prime \prime} T{ }^{\prime \prime}{ }^{\prime}$ is $1 / J\left(g_{a}\right)$, the transition function for the density bundle is

$$
\frac{1}{J\left(g_{a \beta}\right)} \cdot \operatorname{sgn} J\left(g_{a \beta}\right)=\frac{1}{\left|J\left(g_{\alpha \beta}\right)\right|}
$$

Let $\varepsilon_{a}$ be the section of $\left.L\right|_{U_{a}}$ corresponding to 1 under the trivialization of $L$ induced from the atlas $\left\{\left(U_{a}, \phi_{a}\right)\right\}$. If $\phi_{\alpha}=\left(x_{1}, \ldots, x_{n}\right)$ are the coordinates on $U_{\alpha}$, we define the density $\left|d x_{1} \cdots d x_{n}\right|$ in $\left.\Gamma\left(U_{\alpha},\left(\Lambda^{n} T_{M}^{*}\right) \otimes L\right)\right)$ to be

$$
\left|d x_{1} \cdots d x_{n}\right|=e_{a} d x_{1} \cdots d x_{n} .
$$

Locally we may then write a density as $g\left(x_{1}, \ldots, x_{n}\right)\left|d x_{1} \cdots d x_{n}\right|$ for some smooth function $g$.

Let $T: \mathbb{P}^{n} \rightarrow \mathbb{R}^{n}$ be a diffeomorphism of $\mathbb{R}^{n}$ with coordinates $x_{1}, \ldots, x_{n}$ and $y_{1}, \ldots, y_{n}$ respectively. If $\omega=g\left|d y_{1} \ldots d y_{n}\right|$ is a density on $\mathbb{R}^{n}$, the pullback of $\omega$ by $T$ is

$$
\begin{aligned}
T^{*} \omega & =(g \circ T)\left|d\left(y_{1} \circ T\right) \ldots d\left(y_{n} \circ T\right)\right| \\
& =(g \circ T)|J(T)|\left|d x_{1} \ldots d x_{n}\right|
\end{aligned}
$$

The density $g\left|d y_{1} \ldots d y_{n}\right|$ is said to have compact support on $\mathbb{R}^{n}$ if $g$ has compact support, and the integral of such a density over $\mathbb{R}^{n}$ is defined to be the corresponding Riemann integral. Then

$$
\begin{aligned}
\int_{\mathbb{R}^{*}} T^{*} \omega & =\int_{R^{+}}(g \circ T)|J(T)|\left|d x_{1} \ldots d x_{n}\right| \\
& =\int_{R^{*}} g\left|d y_{1} \ldots d y_{n}\right| \text { by the change of variable formula } \\
& =\int_{R^{*}} \omega
\end{aligned}
$$

Thus the integration of a density is invariant under the group of all diffeomorphisms on $\mathbb{R}^{n}$. This means we can globalize the integration of a density to a manifold. If $\left\{\rho_{a}\right\}$ is a partition of unity subordinate to the open cover $\left\{\left(U_{a}, \phi_{a}\right)\right\}$ and $\omega \in \Omega_{c}^{M}(M, L)$, define

$$
\int_{M} \omega=\sum_{a} \int_{\mathbb{R}^{*}}\left(\phi_{a}^{-1}\right)^{*}\left(\rho_{a} \omega\right)
$$

It is easy to check that this definition is independent of the choices involved.
Just as for differential forms there is a Stokes' theorem for densities. We state below only the weak version that we need.

Theorem 7.7 (Stokes' Theorem for Densities). On any manifold $M$ of dimension $n$, orientable or not, if $\omega \in \Omega_{c}^{n^{-1}}(M, L)$, then

$$
\int_{M} d \omega=0
$$

The proof is essentially the same as (3.5).
It follows from this Stokes' theorem that the pairings

$$
\Omega^{q}(M) \otimes \Omega_{c}^{n-q}(M, L) \rightarrow \mathbf{R}
$$

and

$$
\Omega_{c}^{q}(M) \otimes \Omega^{n-q}(M, L) \rightarrow \mathbb{R}
$$

given by

$$
\omega \wedge \tau \mapsto \int_{M} \omega \wedge \tau
$$

descend to cohomology.
Theorem 7.8 (Poincaré Duality). On a manifold $M$ of dimension $n$ with a finite good cover, there are nondegenerate pairings

$$
H^{q}(M) \bigotimes_{\mathbb{R}} H_{c}^{n-q}(M, L) \rightarrow \mathbb{R}
$$

and

$$
H_{c}^{q}(M) \bigotimes_{\mathrm{R}} H^{n-q}(M, L) \rightarrow \mathbf{R}
$$

Proof. By tensoring the Mayer-Vietoris sequences (2.2) and (2.7) with $\Gamma(M, L)$ we obtain the corresponding Mayer-Vietoris sequences for twisted cohomology. The Mayer-Vietoris argument for Poincaré duality on an orientable manifold then carries over word for word.

Corollary 7.8.1. Let $M$ be a connected manifold of dimension $n$ having a finite good cover. Then

$$
H^{n}(M)= \begin{cases}\mathbf{R} & \text { if } M \text { is compact orientable } \\ 0 & \text { otherwise. }\end{cases}
$$

Proof. By Poincare duality, $H^{\prime \prime}(M)=H_{c}^{0}(M, L)$. Let $\left\{U_{a}\right\}$ be a coordinate open cover for $M$. An element of $H_{c}^{0}(M, L)$ is given by a collection of constants $f_{\varepsilon}$ on $U_{\varepsilon}$ satisfying

$$
f_{a}=\left(\operatorname{sgn} J\left(g_{a}\right)\right) f_{p} .
$$

If $f_{a}=0$ for some $\alpha$, then by the connectedness of $M$, we have $f_{a}=0$ for all $\alpha$. It follows that a nonzero element of $H_{c}^{0}(M, L)$ is nowhere vanishing. Thus, $H_{c}^{0}(M, L) \neq 0$ if and only if $M$ is compact and $L$ has a nowherevanishing section, i.e, $M$ is compact orientable. In that case,

$$
H_{c}^{0}(M, L)=H_{c}^{0}(M)=\mathbf{R} .
$$

Exercise 7.9. Let $M$ be a manifold of dimension $n$. Compute the cohomology groups $H_{c}^{\prime \prime}(M), H^{m}(M, L)$, and $H_{c}^{\prime \prime}(M, L)$ for each of the following four cases: $M$ compact orientable, noncompact orientable, compact nonorientable, noncompact nonorientable.

Finally, we state but do not prove the Thom isomorphism theorem in all orientational generality. Let $E$ be a rank $n$ vector bundle over a manifold
$M$, and let $\left\{\left(U_{a}, \phi_{\Delta}\right)\right\}$ and $g_{a \beta}$ be a trivialization and transition functions for $E$. Neither $E$ nor $M$ is assumed to be orientable. The orientation bundle of $E$, denoted $o(E)$, is the line bundle over $M$ with transition functions $\operatorname{sgn} J\left(g_{a \beta}\right)$. With this terminology, the orientation bundle of $M$ is simply the orientation bundie of its tangent bundle $T_{\mathcal{M}}$. It is easy to see that when $E$ is not orientable, integration along the fiber of a form in $\Omega_{c v}^{*}(E)$ does not yield a global form on $M$, but an element of the twisted complex $\Omega^{*}(M, o(E)$ ).

Theorem 7.10 (Nonorientable Thom Isomorphism). Under the hypothesis above, integration along the fiber gives an isomorphism

$$
\pi_{*}: H_{c v}^{*+n}(E) \simeq H^{*}(M, o(E)) .
$$

Exercise 7.11. Compute the twisted de Rham cohomology $H^{*}\left(\mathbb{R} P^{n}, L\right)$.

## CHAPTER II

## The Čech-de Rham Complex

## §8 The Generalized Mayer-Vietoris Principle

Reformulation of the Mayer-Vietoris Sequence
Let $U$ and $V$ be open sets on a manifold. In Section 2, we saw that the sequence of inclusions

$$
U \cup V \leftarrow U \amalg V \text { ょUคV }
$$

gives rise to an exact sequence of differential complexes

$$
0 \rightarrow \Omega^{*}(U \cup V) \rightarrow \Omega^{*}(U) \oplus \Omega^{*}(V) \rightarrow \Omega^{*}(U \cap V) \rightarrow 0
$$

called the Mayer-Vietoris sequence. The associated long exact sequence
$\cdots \rightarrow H^{q}(U \cup V) \xrightarrow{x} H^{q}(U) \oplus H^{q}(V) \xrightarrow{\dot{b}} H^{q}(U \cap V) \xrightarrow{\bullet} H^{q+\frac{1}{2}}(U \cup V) \rightarrow \cdots$
allows one to compute in many cases the cohomology of the union $U \cup V$ from the cohomology of the open subsets $U$ and $V$. In this section, the Mayer-Vietoris sequence will be generalized from two open sets to countably many open sets. The main ideas here are due to Weil [1].

To make this generalization more transparent, we first reformulate the Mayer-Vietoris sequence for two open sets as follows. Let $\mathfrak{u}$ be the open cover $\{U, V\}$. Consider the double complex $C^{*}\left(\mathcal{U}, \Omega^{*}\right)=\oplus K^{8.4}=$ $\oplus C^{p}\left(\mathcal{U}, \Omega^{q}\right)$ where

$$
\begin{aligned}
& K^{0, q}=C^{0}\left(\mathfrak{U}, \Omega^{q}\right)=\Omega^{q}(U) \oplus \Omega^{q}(V), \\
& K^{1, q}=C^{1}\left(\mathfrak{U}, \Omega^{q}\right)=\Omega^{q}(U \cap V), \\
& K^{p, q}=0, \quad p \geq 2 .
\end{aligned}
$$

This double complex is equipped with two differential operators, the exterior derivative $d$ in the vertical direction and the difference operator $\delta$ in the horizontal direction. Of course, $\delta$ is 0 after the first column. Because $d$ and $\delta$ are independent operators, they commute.

In general given a doubly graded complex $K^{* * *}$ with commuting differentials $d$ and $\delta$, one can form a singly graded complex $K^{*}$ by sumiming along the antidiagonal lines

and defining the differential operator to be

$$
D=D^{\prime}+D^{\prime \prime} \text { with } D^{\prime}=\delta, D^{\prime \prime}=(-1) \gamma d \text { on } K^{p \cdot 4} .
$$

Remark on the Defintion of D.

If $D$ were naively defined as $\bar{D}=d+\delta$, it would not be a differential operator since $\tilde{D}^{2}=2 d \delta \neq 0$. However, if we alternate the sign of $d$ from one column to the next, then as is apparent from the diagram above,

$$
D^{2}=d^{2}+\delta d-d \delta+\delta^{2}=0 .
$$

In the sequel we will use the same symbol $C^{*}\left(\mathbb{U}, \Omega^{*}\right)$ to denote the double complex and its associated single complex. In this setup; the MayerVietoris principle assumes the following form.

Theorem 8.1. The double complex $C^{*}\left(u, \Omega^{*}\right)$ computes the de Rham cohomology of $M$ :

$$
H_{D}\left\{C^{*}\left(\mu, \Omega^{*}\right)\right\} \simeq H_{b}{ }^{*}(M)
$$

Proof. In one direction there is the natural map

$$
r: \Omega^{*}(M) \rightarrow \Omega^{*}(U) \oplus \Omega^{*}(V) \subset C^{*}\left(\mu, \Omega^{*}\right)
$$

given by the restriction of forms. Our first observation is that $r$ is a chain map, i.e., that the following diagram is commutative:

This is because

$$
\begin{aligned}
D r & =\left(\delta+(-1)^{r} d\right) r \quad[\text { here } p=0] \\
& =d r \\
& =r d .
\end{aligned}
$$

Consequently $r$ induces a map in cohomology

$$
r^{*}: H_{D_{R}}(M) \rightarrow H_{D}\left\{\left(C^{*}\left(\mu, \Omega^{*}\right)\right\} .\right.
$$

A $q$-cochain $\alpha$ in the double complex $C^{*}\left(\mu, \Omega^{*}\right)$ has two components

$$
\alpha=\alpha_{0}+\alpha_{1}, \quad \alpha_{0} \in K^{0,1}, \quad \alpha_{1} \in K^{1,4-1} .
$$

By the exactness of the Mayer-Vietoris sequence there exists a $\beta$ such that $\delta \beta=\alpha_{1}$. With this choice of $\beta, \alpha-D \beta$ has only the $(0, q)$-component. Thus, every cochain in $C^{*}\left(\mu, \Omega^{*}\right)$ is D-cohomologous to a cochain with only the top component.

We now show $r^{*}$ to be an isomorphism.
Step l. $r^{*}$ is surjective.
By the remark above we may assume that a given cohomology class in $\dot{H}_{D}\left\{C^{*}\left(\mathfrak{U}, \Omega^{*}\right)\right\}$ is represented by a cocycle $\phi$ with only the top component. In this case

$$
D \phi=0 \quad \text { if and only if } \quad d \phi=\delta \phi=0
$$

So $\phi$ is a global closed form.
Step 2. $r^{*}$ is injective.
Suppose $n(\omega)=D \phi$ for some cochain $\phi$ in $C^{*}\left(\mathbb{U}, \Omega^{*}\right)$. Again by the remark above we may write $\phi=\phi^{\prime}+D \phi^{\prime \prime}$, where $\phi^{\prime}$, has only the top component. Then

$$
r(\omega)=D \phi^{\prime}=d \phi^{\prime}, \quad \delta \phi^{\prime}=0
$$

So $\omega$ is the exterior derivative of a global form on $M$.

## Generalization to Countably Many. Open Sets and Applications

Instead of a cover with two open sets as in the usual Mayer-Vietoris sequence, consider the open cover $\mathfrak{U}=\left\{U_{a}\right\}_{a \in J}$ of $M$, where the index set $J$ is a countable ordered set. Of course $J$ may be finite. Denote the pairwise intersections $U_{a} \cap U_{\beta}$ by $U_{a \beta}$, triple intersections $U_{a} \cap U_{\beta} \cap U_{y}$ by $U_{\alpha \beta \gamma}$, etc. There is a sequence of inclusions of open sets

$$
M \leftarrow 【 U_{\alpha_{0}}^{\stackrel{\partial_{0}}{\partial_{1}}} \underset{\leftarrow}{\leftarrow} \coprod_{\alpha_{0}<\alpha_{1}} U_{\alpha_{0} \alpha_{1}} \stackrel{\partial_{0}}{\stackrel{\partial_{1}}{o_{2}}} \coprod_{\alpha_{0}<\alpha_{1}<\alpha_{2}} U_{\alpha_{0} \alpha_{1} \alpha_{2}} \leftleftarrows \ldots
$$

where $\partial_{j}$ is the inclusion which "ignores" the ith open set; for example,

$$
\partial_{0}: U_{\alpha_{0} \alpha_{1} \alpha_{2}} \rightarrow U_{\alpha_{1} \alpha_{2}}
$$

This sequence of inclusions of open sets induces a sequence of restrictions of forms

$$
\Omega^{*}(M) \stackrel{r}{\rightarrow} \prod^{*}\left(U_{\alpha_{0}}\right) \underset{\alpha_{0}<\alpha_{1}}{\Rightarrow} \Omega^{*}\left(\dot{U}_{a_{0} \alpha_{1}}\right) \xrightarrow[{\xrightarrow[\delta_{2}]{\rightarrow}}]{\stackrel{\delta_{0}}{\delta_{0}}} \prod_{\alpha_{1}<\alpha_{2}} \Omega^{*}\left(\dot{U}_{\varepsilon 0 \alpha_{1} \alpha_{2}}\right) \rightrightarrows
$$

where $\delta_{0}$, for instance, is induced from the inclusion

$$
\partial_{0}: \coprod_{\varepsilon} U_{A d x} \rightarrow U_{A \gamma} .
$$

and therefore is the restriction

$$
\delta_{0}: \Omega^{*}\left(U_{\beta_{\gamma}}\right) \rightarrow \coprod_{\varepsilon} \Omega^{*}\left(U_{\Delta \beta}\right)
$$

We define the difference operator $\delta: \Pi \Omega^{*}\left(U_{\alpha_{0} \alpha_{1}}\right) \rightarrow \Pi \Omega^{*}\left(U_{\alpha_{0} \varepsilon_{1} \varepsilon_{2}}\right)$ to be the alternating difference $\delta_{0}-\delta_{1}{ }^{\prime}+\delta_{2}$. Thus

$$
(\delta \xi)_{\alpha_{0} \alpha_{1} \alpha_{2}}=\xi_{\alpha_{1, \alpha_{2}}}-\xi_{\alpha_{0} \alpha_{2}}+\xi_{\alpha 0 \alpha_{1}}:
$$

More generally the difference operator is defined as follows.
Definition 8.2. If $\omega \in\left\lceil\Omega^{9}\left(U_{\text {a0 }} \ldots,{ }_{0}\right)\right.$, then $\omega$ has "components" $\omega_{c 0 . \ldots} *$ $\Omega^{q}\left(U_{a_{0} . . . e_{0}}\right)$ and

$$
(\delta \omega)_{e_{0} \ldots a_{p+1}}=\sum_{t=0}^{p+1}(-1)^{t} \omega_{\alpha_{0} \ldots, \ldots a^{\prime} \ldots \varepsilon_{p}+1},
$$

where on the right-hand side the restriction operation to $U_{\text {ao }} \ldots \boldsymbol{c}_{p+1}$ has been suppressed and the caret denotes omission.

Proposition 8.3. $\delta^{2}=0$.
Proof, Basically this is true because in $\left(\delta^{2} \omega\right)_{e_{0} \ldots c_{p}+2}$ we omit two indicas $\alpha_{l}, \alpha_{l}$ twice with opposite signs. To be precise,

$$
\because
$$

Convention. Up until now the indices in $\omega_{c_{0} . . . \alpha_{p}}$ are all in increasing order $\alpha_{0}<\ldots<\alpha_{p}$. More generally we will allow indices in any order, even with repetitions, subject to the convention that when two indices are inter-* changed, the form becomes its negative:

$$
\omega_{\ldots \ldots \ldots \ldots}=-\omega_{\ldots \ldots \ldots \ldots \ldots}
$$

In particular a form. with repeated indices is $\mathbf{Q}$. In the following exercise the reader is asked to oheck that this convention is consistent with the definition of the difference operator $\delta$ above.

Exercise 8.4. Suppose $\alpha<\beta$. Then ( $\delta \omega$ )........... may be defined either as $-(\delta \omega) \ldots . . . . . . .$. or by the difference operator formula (8.2). Show that theace two definitions agree.

$$
\begin{aligned}
& \left(\delta^{2} \omega\right)_{c_{0} \ldots e_{p+2}}=\sum(-1)^{\prime}(\delta \omega)_{\infty 0 \ldots \mu_{1} \ldots \alpha_{p+2}} \\
& =\sum_{j<1}(-1)^{k}(-1)^{j} \omega_{x_{0}} \ldots ._{1}, \ldots 4_{1} \ldots e_{p+2} . \\
& +\sum_{j>1}(-1)^{\prime}(-1)^{j-1} \omega_{\text {ap }} \ldots a_{4} \ldots e_{j} \ldots a_{p+1} \\
& =0 \text {. }
\end{aligned}
$$

## Proposition 8.5. (The Generalized Mayer-Vietoris Sequence). The sequence

$$
0 \rightarrow \Omega^{*}(M) \stackrel{\ominus}{\longrightarrow} \Pi \Omega^{*}\left(U_{a 0}\right) \stackrel{\partial}{\rightarrow} \Pi \Omega^{*}\left(U_{a 0 \alpha_{1}}\right) \xrightarrow{\partial} \prod \Omega^{*}\left(U_{a 0 \alpha_{142}}\right) \xrightarrow{\partial} \ldots
$$

is exact; in other words, the $\delta$-cohomology of this complex vanishes identically.

Proof. Clearly $\Omega^{*}(M)$ is the kernel of i.e first $\delta$ since an element of $\Pi \Omega^{*}\left(U_{a_{0}}\right)$ is a global form on $M$ if and only if its components agree on the overlaps.

Now let $\left\{\rho_{a}\right\}$ be a partition of unity subordinate to the open cover $\mathfrak{U}=\left\{U_{\alpha}\right\}$. Suppose $\omega \in \prod \Omega^{*}\left(U_{a 0 \ldots \alpha_{\alpha}}\right)$ is a $p$-cocycle. Define a $(p-1)$ cochain $\tau$ by

$$
\tau_{a 0 \ldots a_{p-i}}=\sum_{z} \rho_{z} \omega_{\alpha a_{0} \ldots a_{p-1}}
$$

Then

Because $\omega$ is a cocycle,

$$
\begin{aligned}
(\delta \tau)_{a_{0} \ldots a_{p}} & =\sum_{i}(-1)^{i} \tau_{\alpha_{0} \ldots a_{1} \ldots \alpha_{p}} \\
& =\sum_{i, \alpha}(-1)^{i} \rho_{\alpha} \omega_{a a_{0} \ldots a_{1} \ldots \alpha_{p}}
\end{aligned}
$$

$$
(\delta \omega)_{a a_{0} \ldots a_{p}}=\omega_{a 0 \ldots z_{p}}+\sum_{i}(-1)^{t+1} \omega_{a e_{0} \ldots a_{1} \ldots a_{p}}=0
$$

So

$$
\begin{aligned}
(\delta \tau)_{a_{0} \ldots a_{p}} & =\sum_{a} \rho_{i} \sum_{i}(-1)^{i} \omega_{a \pi 0 \ldots a_{i} \ldots a_{p}} \\
& =\sum_{a} \rho_{a} \omega_{a 0 \ldots a p} \\
& =\omega_{a 0 \ldots a_{p}}
\end{aligned}
$$

This shows that every cocycle is a coboundary. The exactness now follows from Proposition 8.3.

In fact, the definition of $\tau$ in this proof gives a homotopy operator on the complex. Write $K \omega$ for $\tau$ :

$$
\begin{equation*}
(K \omega)_{\alpha_{0} \ldots \alpha_{p-1}}=\sum_{a} \rho_{a} \omega_{a \operatorname{man} \ldots a_{p-1}} \tag{8.6}
\end{equation*}
$$

Then

$$
\begin{aligned}
(\delta K \omega)_{a_{0} \ldots \alpha_{p}} & =\sum(-1)^{i}(K \omega)_{a_{0} \ldots a_{1} \ldots a_{p}} \\
& =\sum(-1)^{i} \rho_{a} \omega_{a a_{0} \ldots a_{1} \ldots \varepsilon_{p}} \\
(K \delta \omega)_{a_{0} \ldots a_{p}} & =\sum \rho_{a}(\delta \omega)_{a \alpha_{0} \ldots \alpha_{p}} \\
& =\left(\sum \rho_{a} k \omega_{a 0 \ldots a_{p}}+\sum(-1)^{i+1} \rho_{a} \omega_{a \omega_{0} \ldots a_{1} \ldots a_{p}}\right. \\
& =\omega_{a_{0} \ldots a_{p}}-(\delta K \omega)_{a_{0} \ldots a_{p}}
\end{aligned}
$$

Therefore, $K$ is an operator from $\left\lceil\Omega^{*}\left(U_{a_{0} \ldots, . . a}\right)\right.$ to $\Pi \Omega^{*}\left(U_{a 0 . . . \varepsilon_{p-1}}\right)$ such that

$$
\begin{equation*}
\delta K+K \delta=1 \tag{8.7}
\end{equation*}
$$

As in the proof of the Poincaré lemma, the existence of a homotopy operator on a differential complex implies that the cohomology of the complex vanishes.

For future reference we note here that if $\phi$ is a cocycle, then by (8.7), $\delta K \phi=\phi$. So on cocycles $K$ is a right inverse to $\delta$. Given $\phi$, the set of all solutions $\xi$ of $\delta \xi=\phi$ consists of $K \phi+\delta$-coboundaries.

The Mayer-Vietoris sequence may be arranged as an augmented double complex
where $K^{p . q}=C^{p}\left(u, \Omega^{q}\right)=\prod \Omega^{q}\left(U_{a_{0} \ldots \mu_{0}}\right)$ consists of the "p-cochains of the cover $\mathfrak{U}$ with values in the $q$-forms." The horizontal maps of the double complex are the difference operators $\delta$ and the vertical ones the exterior derivatives $d$. As before, the double complex may be made into a single complex with the differential operator given by

$$
D=D^{\prime}+D^{\prime \prime}=\delta+(-1)^{p} d
$$

A $D$-cocycle is a string such as $\phi=a+b+c$ with

$$
\begin{aligned}
& d a=0, \\
& \delta a= \pm d b \\
& \delta b= \pm d c \\
& \delta c=0,
\end{aligned}
$$

(To be precise we should write $\delta a=-D^{n} b_{p} \delta b=-D^{n} c$.) So, a $D$-cocycle may be pictured as a "zig-zag."

A $D$-coboundary is a string such as $\phi=a+b+c$ in the figure below, where $a=\delta a_{1}+D^{\prime \prime} a_{2}$, etc.

The double complex

$$
C^{\star}\left(\mathcal{U}, \Omega^{*}\right)=\bigoplus_{p, q \geqslant 0} C^{p}\left(\mathfrak{U}, \Omega^{q}\right)
$$

is called the Cech-de Rham complex, and an element of the Čech-de Rham is called a Čech-de Rham cochain. We sometimes refer to a Cech-de Rham cochain more simply as a D-cochain.

The fact that all the rows of the augmented complex are exact is the key ingredient in the proof of the following.

Proposition 88 (Generalized Mayer-Vietoris Principle). The double complex $C^{*}\left(\mathbb{U}, \Omega^{*}\right)$ computes the de Rham cohomology of $M$; more precisely, the restriction map $r: \Omega^{*}(M) \rightarrow C^{*}\left(u, \Omega^{*}\right)$ induces an isomorphism in cohomology:

$$
r^{*}: H_{D \Omega}^{*}(M) \rightarrow H_{D}\left\{C^{*}\left(\mathbb{U}, \Omega^{*}\right)\right\} .
$$

Proof. Since $\operatorname{Dr}=(\delta+d) r=d r=r d, r$ is a chain map, and so it induces a map $r^{*}$ in cohomology.
Step 1. $r^{*}$ is surjective.

Let $\phi$ be a cocycle relative to $D$. By $\delta$-exactness the lowest component of $\phi$ is $\delta$ of something. By subtracting $D($ something ) from $\phi$, we can remove the lowest companent of $\phi$ and still stay in the same cohomology class as $\phi$.

After iterating this procedure enough times we can move $\phi$ in its cohomology class to a cocycle $\phi^{\prime}$ with only the top component. $\phi^{\prime}$ is a closed global form because $d \phi^{\prime}=0$ and $\delta \phi^{\prime}=0$.

Step 2. $r^{*}$ is injective.

If $r(\omega)=D \phi$, we can shorten $\phi$ as before by subtracting boundaries until it consists of only the top component. Then because $\delta \phi$ is 0 , it is actually a global form on $M$. So $\omega$ is exact.

The proof of this proposition is a very general argument from which we; may conclude: if all the rows of an augmented double complex are exact, then the D-cohomology of the complex is isomorphic to the cohomology of the initial column.

It is natural to augment each column by the kernel of the bottom $d$, denoted $C^{\top}(\mu, R)$. The vector space $C^{\prime}(\mu, R)$ consists of the locally constant functions on the $(p+1)$-fold intersections $U_{\text {mo....p. }}$.

The bottom row

$$
C^{0}(\mu, R) \xrightarrow{\dot{d}} C^{1}(\mathcal{U}, R) \xrightarrow{3} C^{2}(\mu, R) \stackrel{d}{\rightarrow}
$$

is a differential complex, and the homology of this complex, $H^{*}(\mathbf{U}, \mathbf{R})$, is called the Cech cohomology of the cover $U$. This is a purely combinatorial object. Note that the argument for the exactness of the generalized MayerVietoris sequence breaks down for the complex $C^{*}(4, R)$, because here the cochains are locally constant functions so that partitions of unity are not applicable.

If the augmented columns of the complox $C^{*}\left(\mu, \Omega^{*}\right)$ are exact, then the
same argument as in (8.8) will yield an isomorphism between the Cech cohomology and the cohomology of the double complex $\checkmark$

$$
H^{*}(\mathfrak{U}, \mathbb{R}) \leadsto H\left\{C^{*}\left(\mathfrak{u}, \Omega^{*}\right)\right\}
$$

and consequently an isomorphism between de Rham cohomology and Čech cohomology

$$
H_{D R}^{*}(M) \simeq H^{*}(\mathfrak{U}, \mathbb{R}) .
$$

Now the failure of the $p^{\text {th }}$ column to be exact is measured by the cohomology groups

$$
\prod_{\substack{q \geqslant 1 \\ a_{0}<\cdots<a_{p}}} H^{q}\left(U_{a_{0} \ldots a_{p}}\right) .
$$

So if the cover is such that all finite nonempty intersections are contractible, e.g., a good cover, then aH augmented columns will be exact. We have proven

Theorem 8.9 If 11 is a good cover of the manifold $M$, then the de Rham cohomology of $M$ is isomorphic to the Cech cohomology of the good cover

$$
H_{D R}(M) \simeq H(\mathbb{U}, \mathbb{R})
$$

Let us recapitulate here what has transpired so far. First, the basic sequence of inclusions

$$
M \leftarrow U_{x} \leftleftarrows U_{a \beta} \leftleftarrows U_{x \beta \gamma} \leftleftarrows \ldots
$$

gives rise to the diagram

| differential <br> geometry of $0 \rightarrow \Omega^{*}(M) \stackrel{r}{\rightarrow}$ forms | $C^{*}\left(2, \Omega^{*}\right)$ |
| :---: | :---: |
| $\cdots$ |  |

Along the left-hand side is the differential geometry of forms on $M$, along the bottom is the combinatorics of the cover $\mathcal{U}=\left\{U_{a}\right\}$, and in the double complex itself the two are mixed. As the complex is the generalized MayerVietoris sequence, the augmented rows are exact, for any cover. It follows that the de Rham cohomology of $M$ is always isomorphic to the cohomol-
ogy of the double complex:

$$
H_{D R}^{*}(M) \simeq H_{D}\left\{C^{*}\left(\mathcal{U}, \Omega^{*}\right)\right\} .
$$

If in addition $\mathfrak{u}$ is a good cover, then by the Poincare lemma the augmented columns are exact. In that case the Cech cohomology of the cover is also isomorphic to the cohomology of the double complex:

$$
H^{*}(\mathfrak{U}, \mathbb{R}) \simeq H_{D}\left\{C^{*}\left(\mathfrak{U}, \Omega^{*}\right)\right\}
$$

Hence there is' an isomorphism between de Rham and Čech. This result provides us with a way of computing the de Rham cohomology by means of combinatorics, since from Section 5 we know that every manifold has a good cover. All three complexes here can be given product structures, in which case the isomorphisms between them are actually isomorphisms of algebras, as will be shown in (14.28).

A priori there is no reason why different covers of $M$ should have the same Cech cohomology. However, it follows from Theorem 8.9 that

Corollary 8,9D The Čech cohomology $H^{*}(\mathfrak{U}, \mathbb{R})$ is the same for all good coters 4 of $M$.

If a manifold is compact, then it has a finite good cover. For such a cover the Čech cohomology $H^{*}(\mathbb{U}, \mathbb{R})$ is clearly finite-dimensional. Thus,

Corollary 8.9.2. The de Rham cohomology $H_{D R}^{*}(M)$ of a compact manifold is finite-dimensional.

In fact,
Corollary 8.9.3. Wheneter $M$ has a finite good cover, its de Rham cohomology $H_{D R}^{*}(M)$ is finite-dimensional.

Both the proof here and the induction argument in Section 5 of the finite dimensionality of the de Rham cohomology rest on the Mayer-Vietoris sequence, but they are otherwise independent of each other.

## §9 More Examples and Applications of the Mayer-Vietoris Principle

In the previous section we used the Mayer-Vietoris principle to show the isomorphism of the de Rham cohomology of a manifold and the Cech cohomology of a good cover; from this, various corollaries follow. In this section, after some examples in which the combinatorics of a good cover is used to compute the de Rham cohomology, we give an explicit isomor-
phism from Cech to de Rham: given a Cech cocycle, we construct the corresponding global closed differential form by means of a collating formula (9.5) based on the homotopy operator $K$ of (8.6). To conclude the section, we give as another application of the Mayer-Vietoris principle a proof of the Künneth formula valid under the hypothesis that one of the factors has finite-dimensional cohomology.
$F$
Examples: Computing the de Rham Cohomology from the Combinatorics of a Good Cover

Let $U=\left\{U_{a}\right\}$ be an open cover of a manifold $M$. The nerve of $\mathbb{U}$ is a simplicial complex constructed as follows. To every open set $U_{s}$, we associate a vertex $\alpha$. If $U_{k} \cap U_{\beta}$ is nonempty, we connect the vertices $\alpha$ and $\beta$ with an edge. If $U_{a} \cap U_{B} \cap U_{\gamma}$ is nonempty, we fill in the face of the triangle $\alpha \beta \gamma$. Repeating this procedure for all finite intersections gives the nerve of $\mathfrak{U}$, denoted $N(\mathfrak{U})$. For the basics of simplicial complexes, see Croom [1].

Example 9.1 (The circla) Let $\mathfrak{U}=\left\{U_{0}, U_{1}, U_{2}\right\}$ be the good cover of the circle as shown in Figure 9.1. The Cech complex has two terms:

$$
\begin{aligned}
& C^{0}(\mathcal{\mu}, \mathbf{R})=\mathbf{R} \oplus \mathbf{R} \oplus \mathbf{R}=\left\{\left(\omega_{0}, \omega_{1}, \omega_{2}\right) \mid \omega_{a} \text { is a constant on } U_{a}\right\} ; \\
& \left.C^{1}(\mu, \mathbf{R})=\mathbf{R} \oplus \mathbf{R} \oplus \mathbf{R}=\left\{\left(\eta_{01}, \eta_{02}, \eta_{12}\right) \mid \eta_{\alpha}\right\} \text { is a constant on } U_{a \beta}\right\} .
\end{aligned}
$$

Figure 9.1

The coboundary $\delta: C^{0} \rightarrow C^{1}$ is given by $(\delta \omega)_{\mu}=\omega_{\beta}-\omega_{g}$. Therefore,

$$
\text { ker } \delta=\left\{\left(\omega_{0}, \omega_{1}, \omega_{2}\right) \mid \omega_{0}=\omega_{1}=\omega_{2}\right\}=\mathbf{R}
$$

and

$$
H^{0}\left(S^{1}\right)=\mathbf{R}
$$

Since im $\delta=R^{2}, H^{1}\left(S^{1}\right)=R^{3} / \mathrm{im} \delta=R$.

Example 9.2 (A nontrivial 1-cocycle on the circle). If a 1 -cocycle $\eta=$ ( $\eta_{01}$, $\left.\eta_{02}, \eta_{12}\right)$ is a coboundary, then $\eta_{01}-\eta_{02}+\eta_{12}=0$. So $\eta=(1,0,0)$ is a nontrivial 1-cocycle on the circle.
Example 9.3 (The 2-sphere). Cover the lower hemisphere of Figure 9.2 with three open sets as in Figure 9.3. Together with the upper hemisphere $U_{0}$, this gives a good cover of the entire sphere. The nerve of the cover is the surface of a tetrahedron as depicted in Figure 9.4. The Cech complex has

Figure 9.2

Figure 9.3

Figure 9.4
three terms:

$$
\begin{aligned}
& \text { ker } \delta_{0}=\left\{\left(\omega_{0}, \omega_{1}, \omega_{2}, \omega_{3}\right) \mid \omega_{0}=\omega_{1}=\omega_{2}=\omega_{3}\right\}=\mathbb{R}
\end{aligned}
$$

So im $\delta_{0}=\mathbb{R}^{3}$ and $H^{0}\left(S^{2}\right)=\mathbb{R}$. If $\eta$ is in ker $\delta_{1}$, then $\eta$ is completely determined by $\eta_{01}, \eta_{02}$, and $\eta_{03}$. Therefore ker $\delta_{1}=\mathbb{R}^{3}$ and

$$
H^{1}\left(S^{2}\right)=\operatorname{ker} \delta_{1} / \operatorname{im} \delta_{0}=0
$$

Since im $\delta_{1}=C^{1} / \operatorname{ker} \delta_{1}=\mathbb{R}^{3}$,

$$
H^{2}\left(S^{2}\right)=\mathbb{R}^{4} / \mathrm{im} \delta_{1}=\mathbb{R}
$$

Explicit Isomorphisms between the Double Complex and de Rham and Cech

We saw in Proposition 8.8 that the Čech-de Rham complex $C^{*}\left(\mu, \Omega^{*}\right)$ and the de Rham complex $\Omega^{*}(M)$ have the same cohomology. Actually, what is true is that these two complexes are chain homotopic. To be more precise, there is a chain map

$$
\begin{equation*}
f: C^{*}\left(\boldsymbol{\mu}, \Omega^{*}\right) \rightarrow \Omega^{*}(M) \tag{9.4}
\end{equation*}
$$

such that
(a) $f=r=1$, and
(b) $r \circ f$ is chain homotopic to the identity.

We may think of $f$ as a recipe for collating together the components of a Čech-de Rham cochain into a global form. The not very intuitive formulas below were obtained, after repeated tries, by a careful bookkeeping of the inductive steps in the proof of Proposition 8.8.

Proposition 9.5 (The Collating Formula). Let $K$ be the homotopy operator defined in (8.6). If $\alpha=\sum_{i=0}^{n} \alpha_{i}$ is an $n$-cochain and $D \alpha=\beta=\sum_{i=0}^{n+1} \beta_{i}$, then

$$
f(\alpha)=\sum_{i=0}^{n}\left(-D^{\prime \prime} K\right)^{i} \alpha_{i}-\sum_{i=0}^{n+1} K\left(-D^{\prime \prime} K\right)^{i-1} \beta_{i} \in C^{0}\left(\mathfrak{U}, \Omega^{n}\right)
$$

is a global form satisfying the properties above. The homotopy operator

$$
L: C^{*}\left(\mathbf{l}, \Omega^{*}\right) \rightarrow C^{*}\left(\mathcal{U}, \Omega^{*}\right)
$$

such that $1-r: f=D L+L D$ is given by

$$
L \alpha=\sum_{p=0}^{n-1}(L \alpha)_{p},
$$

where

$$
(L x)_{p}=\sum_{i=p+1}^{n} K\left(-D^{\prime \prime} K\right)^{i-(p+1)} x_{i} \in C^{p}\left(L I, \Omega^{n-1-p}\right) .
$$

$\therefore 11$

Remark. To strip away some of the mysteries in the expression for $f(\alpha)$, it may be heipful to observe that the operator $D^{\prime \prime} K$ sends an element of $C^{p}\left(\mu, \Omega^{q}\right)$ into $C^{p-1}\left(\mathcal{U}, \Omega^{+1}\right)$, so that $\left(D^{\prime \prime} K\right)^{i} \alpha_{i}$ and $K\left(D^{\prime \prime} K\right)^{i-1} \beta_{i}$ are collections of $n$-forms on the open sets $U_{\alpha}$. The collating formula says that a suitable linear combination of these local $n$-forms, with $\pm 1$ as coefficients, is the restriction of a global form.

The proof of Proposition 9.5 requires the following technical lemma.

## Lemma 9.6.

$$
\delta\left(D^{\prime \prime} K\right)^{i}=\left(D^{\prime \prime} K\right)^{i} \delta-\left(D^{\prime \prime} K\right)^{i-i} D^{\prime \prime}
$$

Proof of Lfmma 9.6. Since $\dot{\delta}$ anticommutes with. $D^{\prime \prime}$ and . sipue. $\delta K+K \delta=1$,

$$
\begin{aligned}
\left.\dot{\delta}\left(D^{\prime \prime} K\right) X D^{\prime \prime} K\right)^{i-1} & =-D^{\prime \prime} \partial K\left(D^{\prime \prime} K\right)^{i-1} \\
& =-D^{\prime \prime}(1-K \delta)\left(D^{\prime \prime} K\right)^{i-1} \\
& =\left(D^{\prime \prime} K\right) \dot{\delta}\left(D^{\prime \prime} K\right)^{i-1}
\end{aligned}
$$

So we can commute $D^{\prime \prime} K$ and $\delta$ until we reach $\left(D^{\prime \prime} K\right)^{i-1} \delta\left(D^{\prime \prime} K\right)$. Then,

$$
\begin{aligned}
\dot{\delta}\left(D^{\prime \prime} K\right)^{i} & =\left(D^{\prime \prime} K\right)^{i-1} \delta\left(D^{\prime \prime} K\right) \\
& =-\left(D^{\prime \prime} K\right)^{i+1} D^{\prime \prime}(1-K \delta) \\
& =-\left(D^{\prime \prime} K\right)^{i-1} D^{\prime \prime}+\left(D^{\prime \prime} K\right)^{i} \delta .
\end{aligned}
$$

Proof of Proposition 9.5. To show that $f(\alpha)$ is a global form, we compute $\delta f(\alpha)$. Using the lemma above and the fact that $\delta \alpha_{1}+D^{\prime \prime} \alpha_{1+1}=\beta_{1+1}$, this is a straightforward exercise which we leave to the reader.

Exercise 9.7. Show that $\delta f(\alpha)=0$.
Next we check that $f$ is a chain map.

$$
\begin{aligned}
& f(D \alpha)=f(\beta)=\sum_{i=0}^{n+1}(-1)^{i}\left(D^{\prime \prime} K\right)^{i} \beta_{i} \\
& d f(\alpha)=D^{\prime \prime} f(\alpha)=\beta_{0}+\sum_{i=1}^{n+1}(-1)^{i}\left(D^{\prime \prime} K\right)^{i} \beta_{i}
\end{aligned}
$$

So

$$
f(D \alpha)=d f(\alpha)
$$

The verification of Property (a) is easy, since if $\alpha$ is a global form, then $\alpha=\alpha_{0}$ and

$$
f \circ n(\alpha)=f(\alpha)=\alpha_{0}=\alpha
$$

Property (b) follows from the fact that

$$
1-r \circ f=D L+L D
$$

As its verification is straightforward and not very illuminating, we shall omit it. The skeptical reader may wish to carry it out for himself. Apart from the definitions, the only facts needed are Lemma 9.6 and the chainhomotopy formula (8.7).

Remark. Actually the existence of the chain-homotopy inverse $f$ and the homotopy operator $L$ is guaranteed by a general principle in the theory of chain complexes (See Spanier [1, Ch. 4, Sec. 2; in particular, Cor. ii, p. 167]).

We can now give an explicit description of the varicus isomorphisms that follow from the generalized Mayer-Vietoris principle. For example, by applying the collating formula (9.5), we get

Proposition 9.8 (Explicit Isomorphism between de Rham and Cech). If $\eta \in$ $C^{n}(\mu, \mathbf{R})$ is a Cech cocycle, then the global closed form corresponding to it is given by $f(\eta)=(-1)^{7}\left(D^{\prime \prime} K\right)^{n} \eta$.

EXample 9.9. Let $\mathbb{U}$ be a good cover of the circle $S^{1}$. We shall construct - from a generator of the Cech cohomology $H^{1}(\mathcal{U}, \mathrm{R})$ a differential form representing a generator of the de Rham cohomology $H_{D r}^{1}\left(S^{1}\right)$.

As we saw in Example 9.2, a nontrivial 1-cocycle on $S^{1}$ is

$$
\eta=\left(\eta_{01}, \eta_{02}, \eta_{12}\right)=(1,0,0)
$$

If $\left\{\rho_{\varepsilon}\right\}$ is a partition of unity, then

$$
K \eta=\left(-\rho_{1}, \rho_{0}, 0\right) .
$$

So the generator $-D^{\prime \prime} K \eta$ of $H_{D R}^{1}\left(S^{1}\right)$ is represented by $-d\left(-\rho_{1}\right)$, a bump form on $U_{0} \cap U_{1}$ with total integral 1 .

Exercise 9.10. The real projective plane $\mathbb{R} P^{2}$ is obtained by identifying the boundary of a disc as shown in Figure 95. Find a good cover for R $P^{\mathbf{2}}$ and

Figure 9.5
compute its de Rham cohomology from the combinatorics of the cover. One possible good cover has the nerve depicted in Figure 9.6.

Figure 9.6

Exercise 9.11. Let Figure 9.7 be the nerve of a good cover $\mathfrak{U}$ on the torus, where the arrows indicate how the vertices are ordered. Write down a nontrivial 1-cocycle in $C^{1}(\mathbf{U}, \mathrm{R})$.

## The Tic-Tac-Toe Proof. of the Künneth Formula

We now apply the main theorems of the preceding section to give another proof of the Künneth formula. This proof, admittedly more involved in its

Figure 9.7
construction than the Mayer-Vietoris argument of Section 5, is a prototype for the spectral sequence argument of Chapter III. It will also allow us to replace the requirement that $M$ has a finite good cover by the slightly weaker hypothesis that $F$ has finite-dimensional cohomology.

Before commencing the proof we make some general remarks about a technique for studying maps. Let $\pi: E \rightarrow M$ be a map of manifolds. A cover $\mathfrak{U}$ on $M$ induces a cover $\pi^{-1} \mathfrak{U}$ on $E$, and we have the inclusions

$$
\begin{aligned}
& E \leftarrow\left\lfloor\pi ^ { - 1 } U _ { \alpha } \leftleftarrows \left\lfloor\pi^{-1} U_{x \beta} \leftleftarrows \cdots\right.\right. \\
& M \leftarrow \coprod U_{z} \quad \leftleftarrows \bigcup U_{\alpha \beta} \quad \leftleftarrows \cdots .
\end{aligned}
$$

In general $U_{a} \cap U_{\hat{p}} \neq \phi$ is not equivalent to $\pi^{-1} U_{a} \cap \pi^{-1} U_{\beta} \neq \phi$. However, if $\pi$ is surjective, then the two statements are equivalent, so that in this case the combinatorics of the covers $\mathfrak{U}$ and $\pi^{-1} \mathfrak{U}$ are the same. The double complex of the inverse cover computes the cohomology of. $E$, which can then be related to the cohomology of $M$, because the inverse cover comes from a cover on $M$. This idea will be systematically exploited throughout this chapter and the next.

A quick example of how the inverse cover $\pi^{-1} \mathfrak{U}$ may be used to study maps is the following. Note that although the inverse image of a good cover is usually not a good cover, for a vector bundle $\pi: E \rightarrow M$ the "goodness" of the cover is preserved. Since the de Rham cohomology is determined by the combinatorics of a good cover, this implies that

$$
\ldots \quad H_{D R}^{*}(E) \simeq H_{D R}^{*}(M) .
$$

Of course, this also follows from the homotopy axiom for the de Rham cohomology (Corollary 4.1.2.2).

Proposition 9.12 (Künneth Formula). If $M$ and $F$ are two manifolds and $F$ has finite-dimensional cohomology, then the de Rham cohomology of the product $M \times F$ is

$$
H^{*}(M \times F)=H^{*}(M) \otimes H^{*}(F)
$$

Proof. Let $\mathfrak{U}=\left\{U_{a}\right\}$ be a good cover for $M$ and $\pi: M \times F \rightarrow M$ the projection onto the first factor. Then $\pi^{-1} \mathfrak{U}=\left\{\pi^{-1} U_{\alpha}\right\}$ is some sort of a cover for $E=M \times F$, though in general not a good cover. There is a natural map

which pulls back differential forms on open sets. Choose a basis for $H^{*}(F)$, say $\left\{\left[\omega_{\alpha}\right]\right\}$, and choose differential forms $\omega_{\alpha}$ representing them. These may be used to define a map of double complexes

$$
\begin{gathered}
C^{*}\left(\pi^{-1} \mathfrak{U}, \Omega^{*}\right) \\
\hat{ई}_{\mathfrak{z}}^{*} \\
H^{*}(F) \otimes C^{*}\left(\mathfrak{U}, \Omega^{*}\right)
\end{gathered}
$$

by

$$
\pi_{u}^{*}\left(\left[\omega_{\alpha}\right] \otimes \phi\right)=\rho^{*} \omega_{a} \wedge \pi^{*} \phi
$$

where $\rho$ is the projection on the fiber

M.

Since $H^{*}(F)$ is a vector space, $H^{*}(F) \otimes C^{*}\left(\mathcal{U}, \Omega^{*}\right)$ is a number of copies of $C^{*}\left(\mu, \Omega^{*}\right)$ and the differential operator $D$ on the double complex $C^{*}\left(\mu, \Omega^{*}\right)$ induces an operator on $H^{*}(F) \otimes C^{*}\left(\mu, \Omega^{*}\right)$ whose cohomology is :

$$
H^{*}(F) \otimes H_{D}\left\{C^{*}\left(\boldsymbol{U}, \Omega^{*}\right)\right\}=H^{*}(F) \otimes H^{*}(M) .
$$

Since the D-cohomology of $C^{*}\left(\pi^{-1} u, \Omega^{*}\right)$ is $H^{*}(E)$, if we can show that

induces an isomorphism in $D$-cohomology, the Künneth formula will follow.

The proof now divides into two steps:
Step 1.
For a good cover $u_{\text {, }}$ the map $\pi_{1:}^{*}$ induces an isomorphism in $H_{d}$ of these complexes.

Step 2.
Whenever a homomorphism $f: K \rightarrow K^{\prime}$ of double complexes induces $\boldsymbol{H}_{\boldsymbol{c}}$-isomorphism, it also induces $\boldsymbol{H}_{\boldsymbol{D}}$-isomorphism. (By a homomorphism of double complexes, we mean a vector-space homomorphism which presetves bidegrees and commutes with $\boldsymbol{d}$ and $\delta$.)

Proof of step 1. The $p^{\text {th }}$ column $C^{p}\left(\pi^{-1} \mathfrak{U}, \Omega^{*}\right)$ consists of forms on the ( $p+1$ )-fold intersections $\amalg \pi^{-1} U_{\alpha_{0} \ldots \ldots p}$ and $C^{p}\left(\mathfrak{U}, \Omega^{*}\right)$ consists of forms on $\mathbf{U} U_{\alpha_{0}} \ldots a_{p}$. The $d$-cohomology of $C^{p}\left(\pi^{-1} \mathfrak{U}, \Omega^{*}\right)$ is

$$
\begin{equation*}
\prod H^{*}\left(\pi^{-1} U_{a_{0} \ldots \alpha_{p}}\right) \simeq H^{*}(F) \otimes \prod H^{*}\left(U_{a_{0} \ldots \alpha_{p}}\right), \tag{9.12.1}
\end{equation*}
$$

the isomorphism being given by the wedge product of pullbacks. So $\pi_{\text {t }}^{*}$ induces an isomorphism of the d-cohomology of $C^{*}\left(\pi^{-1} u, \Omega^{*}\right)$ and $H^{*}(F) \otimes C^{*}\left(\mathbb{U}, \Omega^{*}\right)$.

## Exercise 9.13. Give a proof of Step 2.

Remark. This argument for the Künneth formula also proves the LerayHirsch theorem (5.11), but again instead of assuming that $M$ has a finite good cover, we require the cohomology of $F$ to be finite-dimensional. If both $M$ and $F$ have infinite-dimensional cohomology, the isomorphism in (9.12.1) may not be valid.

The following example shows that some sort of finiteness hypothesis is necessary for the Künneth formula or the Leray-Hirsch theorem to hold.

Example 9.14 (Counterexample to the Künneth formula when both $M$ and $F$ have infinite-dimensional cohomology). Let $M$ and $F$ each be the set $\mathbb{Z}^{+}$ of all positive integers. Then

$$
H^{0}(M \times F)=\left\{\text { square matrices of real numbers }\left(a_{i}\right), i, j \in \mathbb{Z}^{+}\right\} .
$$

But $H^{0}(M) \otimes H^{0}(F)$ consists of finite sums of matrices $\left(a_{i j}\right)$ of rank 1. These two vector spaces are not equal, since a finite sum of matrices of rank 1 has finite rank, but $H^{0}(M \times F)$ contains matrices of infinite rank.

## §10 Presheaves and Čech Cohomology

Presheaves
The functor $\Omega^{*}()$ which assigns to every open set $U$ on a manifold the differential forms on $U$ is an example of a presheaf. By definition a presheaf $F$ on a topological space $X$ is a function that assigns to every open set $U$ in
$X$ an abelian group $\mathscr{F}(U)$ and to every inclusion of open sets

$$
i_{U}^{V}: V \rightarrow U
$$

a group homomorphism, called the restriction,

$$
\mathscr{F}\left(i_{U}^{V}\right): \mathscr{F}(U) \rightarrow \mathscr{F}(V)
$$

satisfying the following properties:
(a) $\mathscr{F}\left(i_{V}^{V}\right)=$ identity map
(b) transitivity: $\mathscr{F}\left(i_{V}^{W}\right) \mathscr{F}\left(i_{v}^{V}\right)=\mathscr{F}\left(i_{v}^{W}\right)$.

The restriction $\mathscr{F}\left(i_{U}^{V}\right): \mathscr{F}(U) \rightarrow \mathscr{F}(V)$ is often denoted $\rho_{V}^{U}$. A homomorphism of two presheaves, $f: \mathscr{F} \rightarrow \mathscr{G}$, is a collection of maps $f_{U}: \mathscr{F}(U) \rightarrow \mathscr{F}(U)$ which commute with the restrictions:

$$
\begin{aligned}
& \stackrel{f_{v}}{\mathscr{F}(U)} \xrightarrow{\rightarrow} \mathscr{G}(U): \\
& \rho_{V}^{v} \downarrow \\
& \mathscr{F}(V) \underset{f_{v}}{\longrightarrow} \mathscr{G}(V)
\end{aligned}
$$

Let $\operatorname{Open}(X)$ be the category whose objects are the open sets in $X$ and whose morphisms are inclusions of open sets. In functorial language, a presheaf is simply a contravariant functor from the category $\operatorname{Open}(X)$ to the category of Abelian groups, and a homomorphism of two presheaves, $f: \mathscr{F} \rightarrow \mathscr{G}$, is a natural iranisformation from the functor $\mathscr{F}$ to the functor $\mathscr{G}$.

The trivial presheaf with group $G$ is the presheaf $\mathscr{F}$ which associates to every connected open set the group $G$ and to every inclusion $V \in U$ the identity map: $\mathscr{F}(U) \rightarrow \mathscr{F}(V)$. We say that a presheaf is a constant presheaf if it is isomorphic to the trivial presheaf, and that it is a locally constant presheaf if it is locally isomorphic to the trivial presheaf, i.e., every point has, a neighborhood $U$ so that $\left.\mathscr{F}\right|_{U}$ is a constant presheaf.

Example 10.1. Let $\pi: E \rightarrow M$ be a fiber bundle with fiber $F$. Define a presheal $\mathscr{H}^{q}$ on $M$ by $\mathscr{H}^{q}(U)=H^{q}\left(\pi^{-1} U\right)$. For $U$ contractible, $H^{q}\left(\pi^{-1} U\right)=$; $H^{q}(F)$ by the Künneth formula, and if $V \subset U$ with $V$ connected, then the. restriction $\rho_{V}^{U}: H^{q}\left(\pi^{-1} U\right) \rightarrow H^{q}\left(\pi^{-1} V\right)$ is the identity. Therefore $\mathscr{X}^{q}$ is a locally constant presheaf on $M$.

Now consider the trivial bundle $E=M \times F$. Assume that $F$ has finite-: dimensional cohomology. Since $\mathscr{H}^{q}(M)=H^{q}(E)=\bigoplus_{i+j=q}\left(H^{i}(M) \otimes\right.$ $H^{j}(F)$ ) is not usually equal to $H^{q}(F)$, a locally constant presheaf on $M$ need not be a constant presheaf, even if $M$ is simply connected.*

[^1]
## Cech Cohomology

Let $\mathfrak{U}=\left\{U_{\alpha}\right\}_{a}$, be an open cover of the topological space $X$. The 0 cochains on $U$ with values in the presheaf $\mathscr{F}$ are functions which assign to each open set $U_{a}$ an element of $\mathscr{F}\left(U_{\alpha}\right)$, i.e., $C^{0}(\mathbb{L}, \mathscr{F})=\Pi_{\text {ee }} \mathscr{F}\left(U_{a}\right)$. Similarly the 1 -cochains are elements of

$$
C^{1}(\mathfrak{U}, \mathscr{F})=\prod_{a<\beta} \mathscr{F}\left(U_{a} \cap U_{\beta}\right)
$$

and so on.
The sequence of inclusions

$$
U_{a} \stackrel{o_{0}}{\stackrel{\partial_{1}}{\leftrightarrows}} U_{a \beta} \leftleftarrows \cdots
$$

gives rise to a sequence of group homomorphisms

$$
\Pi \mathscr{F}\left(U_{n}\right) \rightrightarrows \prod \prod^{F}\left(U_{a \beta}\right) \rightrightarrows
$$

We define $\delta: C^{\prime}(\mu, S) \rightarrow C^{p+1}(4, g)$ to be the alternating difference of the $\mathscr{F}\left(\delta_{1}\right)$ 's; for example,

$$
\delta: C^{0}(\mathfrak{U}, \mathscr{F}) \rightarrow C^{1}(\mathfrak{u}, \mathscr{F})
$$

is given by

$$
\delta=\mathscr{F}\left(\partial_{0}\right)-\mathscr{F}\left(\partial_{1}\right)
$$

In general

$$
\delta: C^{\top}(4, F) \rightarrow C^{p+1}(4, F)
$$

is given by

$$
\delta=\mathscr{F}\left(\partial_{0}\right)-\mathscr{F}\left(\partial_{1}\right)+\cdots+(-1)^{p+1} \mathscr{F}\left(\partial_{p+1}\right)
$$

Explicitly, if $\omega \in C^{P}(4, \mathscr{F})$, then

$$
\begin{equation*}
(\delta \omega)_{\alpha_{0} \ldots a_{p+1}}=\sum_{s=0}^{p+1}(-1)^{\prime} \omega_{a_{0} \ldots \alpha_{1} \ldots a_{p+1}} \tag{10.2}
\end{equation*}
$$

where on the right-hand side the restriction of $\omega_{\alpha_{0} \ldots \alpha_{1} \ldots \alpha_{p+1}}$ to $U_{a_{0} \ldots \alpha_{p+1}}$ is suppressed. It follows from the transitivity of the restriction homomorphism that $\delta^{2}=0$ (proof as in Proposition 8.3). Thus $C^{*}(u, F)$ is a differential complex with differential operator $\delta$. The cohomology of this complex, denoted by $H_{s} C^{*}\left(\mu_{3}\right)$ or $H^{*}(4, F)$, is called the Cech cohomology of the cover 4 with values in $F$.

Remark 10.3. If $T$ is a covariant functor from the category $\operatorname{Open}(X)$ to the category of Abelian groups, and $\boldsymbol{u}$ is an open cover of $X$, one can define analogously a chain complex $C_{*}(u, F)$ and its homology $H_{*}(u, F)$. Apart from the direction of the arrows, the only difference from the case of a
presheaf is in the definition of the coboundary operator $\delta: C_{p}(u, S) \rightarrow$ $C_{p-1}(4,5)$, which is now given by

$$
(\delta \omega)_{a_{0} \ldots c_{p-1}}=\sum_{\varepsilon} \omega_{\operatorname{mon} 0 \ldots c_{p-1}}
$$

One verifies easily that this $\delta$ also satisfies $\delta^{2}=0$. The functor $\mathscr{X}_{c}$ which associates to every open set $U$ on a manifold the compact cohomology $H_{c}^{?}(U)$ is covariant.

Because of the antisymmetry convention on the subscripts, in this formula there is no sign in the sum. Of course, if we had written each term $\omega_{a_{0} \ldots \alpha_{p-1}}$ with the subscript $\alpha$ inserted in the i-th place, then there would be a sign: $\sum_{(-1)^{i} \omega_{\alpha 0} \ldots \text { a ... ap-1• } . ~}^{\text {. }}$

Returning to the discussion of the Cech cohomology of a presheaf $\mathscr{F}$, recall that the cover $\mathfrak{B}=\left\{V_{p}\right\}_{\beta, J}$ is a refinement of the cover $\mathbb{U}=\left\{U_{a}\right\}_{a \in I}$, written $\boldsymbol{U}>\mathfrak{B}$, if there is a map $\phi: J \rightarrow I$ such that $V_{\beta} \subset U_{\phi(\beta)}$. The refinement $\phi$ induces a map

$$
\phi^{*}: C^{4}(4, \mathscr{F}) \rightarrow C^{4}(\mathfrak{B}, \mathscr{F})
$$

in the obvious manner:

$$
\left(\phi^{*} \omega\right)\left(V_{\beta_{0}} \ldots \beta_{8}\right)=\omega\left(U_{\phi}\left(f_{0} \ldots\left(\beta_{0}\right)\right) .\right.
$$

Lemmia 10.4.1. $\phi^{*}$ is a chain map, i.e., it commutes with $\delta$.

Proof.

$$
\begin{aligned}
& \left(\delta\left(\phi^{*} \omega\right)\right)\left(V_{\beta_{0} \ldots \beta_{q}+1}\right)=\sum(-1)^{i}\left(\phi^{*} \omega\right)\left(V_{\beta_{0}-\beta_{1-\beta_{1-1}}}\right) \\
& =\sum(-1)^{i} \omega\left(U_{\left.\alpha \beta_{0}-\ldots \beta_{0}-\omega_{\rho_{1}}\right)}\right) \\
& \left(\phi^{\prime \prime} \delta \omega\right)\left(V_{D_{0} \ldots \rho_{q}+1}\right)=(\delta \omega)\left(U_{\phi\left(\mu_{0}\right)} \ldots \mu_{++1}\right) \\
& =\sum(-1)^{d} \omega\left(U_{\phi\left(\beta_{0}\right)} \ldots \hat{\omega}(1) \ldots\left(h_{p+1}\right)\right) .
\end{aligned}
$$

Lemma 10.4.2. Given $\mathbb{U}=\left\{U_{a}\right\}_{a \in 1}$ an open cover and $B=\left\{V_{\beta}\right\}_{B, J}$ a refinement, if $\phi$ and $\psi$ are two refinement maps: $J \rightarrow I$, then there is a homotopy operator between $\phi^{*}$ and $\psi^{*}$.

Proof. Define $K: C^{q}(\mu, F) \rightarrow C^{q-1}(9,5)$ by

$$
(K \omega)\left(V_{p_{0} \ldots: \beta_{8}-1}\right)=\sum(-1)^{\prime} \omega\left(U_{*\left(\beta_{0}\right) \ldots} \ldots\left(\beta_{0}\right)\left(\beta_{1}\right) \ldots \omega \alpha_{4-1}\right) .
$$

Exercise 10.5. Show that

$$
\psi^{*}-\phi^{*}=8 K+K \delta
$$

A direct system of groups is a collection of groups $\left\{G_{i}\right\}_{i \in!}$ indexed by a directed set $I$ such that for any pair $a>b$ there is a group homomorphism $f_{b}^{a}: G_{a} \rightarrow G_{b}$ satisfying
(1) $f_{a}^{a}=$ identity,
(2) $f_{c}^{a}=f_{c}^{b} \circ f_{b}^{a}$.

On the disjoint union $\amalg G_{i}$ we introduce an equivalence relàtion $\sim$ by decreeing two elements $g$ in $G_{a}$ and $h$ in $G_{b}$ to be equivalent if there is some $c$ in $I$ such that $f_{c}^{a}(g)=f_{c}^{b}(h)$ in $G_{c}$. The direct limit of the direct system, denoted by $\lim _{i \in I} G_{i}$, is the quotient of $\amalg G_{i}$ by the equivalence relation $\sim$; in other words, two elements of $\amalg G_{i}$ represent the same element in the direct limit if they are "eventually equal".

It follows from the two lemmas above that if $\mathfrak{U}>\mathfrak{B}$, then there is a well-defined map in cohomology

$$
H^{*}(\mathbb{U}, \mathscr{F}) \rightarrow H^{*}(\mathfrak{B}, \mathscr{F})
$$

making $\left\{H^{*}(\mathfrak{H}, \mathscr{F})\right\}_{U}$ into a direct system of groups. The direct limit of this direct system.

$$
H^{*}(X, \mathscr{F})=\lim _{\mathfrak{u}} H^{*}(\mathfrak{U}, \mathscr{F})
$$

is the Čech cohomology of $X$ with values in the presheaf $\mathscr{F}$.
Proposition 10.6. Let $\mathbb{R}$ be the constant presheaf on a manifold $M$. Then the Clech cohomology of $M$ with values in is isomorphic to the de Rham cohomology.

Proof. Since the good covers are cofinal in the set of all covers of $M$ (Corollary 5.2), we can use only good covers in the direct limit

$$
H^{*}(M, \mathbb{R})=\lim _{u} H^{*}(\mathfrak{U}, \mathbb{R}) .
$$

By Theorem 8.9,

$$
H^{*}(\mathfrak{U}, \mathbb{R}) \simeq H_{D R}^{*}(M)
$$

for any good cover of $M$. Therefore, there is an isomorphism

$$
H^{*}(M, \mathbb{R}) \simeq H_{D R}^{*}(M)
$$

Exercise 10.7 (Cohomology with Twisted Coefficients). Let 9 be the presheaf on $S^{1}$ which associates to every open set the group $\mathbb{Z}$. We define the
restriction homomorphism on the good cover $\mathbb{U}=\left\{U_{0}, U_{1}, U_{2}\right\}$ (Figure 10.1) by

$$
\begin{aligned}
& \rho_{01}^{0}=\rho_{01}^{1}=1 \\
& \rho_{12}^{1}=\rho_{12}^{2}=1, \\
& \rho_{02}^{2}=-1, \rho_{02}^{0}=1
\end{aligned}
$$

where $\rho_{i j}^{i}$ is the restriction from $U_{i}$ to $U_{i} \cap U_{j}$. Compute $H^{*}\left(\Psi, \sigma_{j}\right)$.

Figure 10.1

## §11 Sphere Bundles

Let $\pi: E \rightarrow M$ be a fiber bundle with fiber the sphere $S^{n}, n \geq 1$. As the structure group we normally take the largest group possible, namely the diffeomorphism group Diff( $S^{\prime \prime}$ ), but sometimes we also consider sphere bundles with structure group $O(n+1)$. These two notions are not equivalent; there are examples of sphere bundles whose structure groups cannot be reduced to the orthogonal group. Thus, every vector bundle defines a sphere bundle, but not conversely. By the Leray-Hirsch theorem if there is a closed global $n$-form on $E$ whose restriction to each fiber griperates the cohomology of the fiber, then the cohomology of $E$ is

$$
H^{*}(E)=H^{*}(M) \otimes H^{*}\left(S^{\prime \prime}\right)
$$

It is therefore of interest to know when such a global form exists.
In Section 6 we constructed the global angular form $\psi$ on a rank 2 vector bundle with structure group SO(2). This form $\psi$ was seen to have the following two properties:
(a) $\psi$ restricts to the volume form on each fiber
(b) $d \psi=-\pi^{*} e$
where $e$ is the Euler class. Exactly the same procedure defincs the angular form and the Euler class of a circle bundle with structure group SO(2)

Consequently, for such a bundle also, if the Euler class vanishes, then $\psi$ is closed and satisfies the condition of the Leray-Hirsch theorem.

We now consider more generally a sphere bundle with structure group $\operatorname{Diff}\left(S^{\prime \prime}\right)$ or $O(n+1)$. We will see that the existence of a global form as above entails overcoming two obstructions: orientability and the Euler class.

Orientability

In this section the base space of the bundle is assumed to be connected. A sphere bundle with fiber $S^{n}, n \geq 1$, is said to be orientable if for each fiber $F_{x}$ it is possible to choose a generator [ $\sigma_{x}$ ] of $H^{n}\left(F_{x}\right)$ satisfying the local compatibility condition: around any point there is a neighborhood $U$ and a generator $\left[\sigma_{U}\right]$ of $H^{\prime \prime}\left(\left.E\right|_{U}\right)$ such that for any $x$ in $U,\left\lceil\sigma_{n}\right\rceil$ restricted to the fiber $F_{x}$ is the chosen generator $\left[\sigma_{x}\right]$; equivalently, there is an open cover $\left\{U_{a}\right\}$ of $M$ and generators $\left[\sigma_{\alpha}\right]$ of $H^{\prime \prime}\left(\left.E\right|_{v_{\alpha}}\right)$ so that $\left[\sigma_{\alpha}\right]=\left[\sigma_{\mu}\right]$ in $H^{n}\left(\left.E\right|_{v_{a} \cap v_{p}}\right)$.

Since a generator of the top cohomology of a fiber is an $n$-form with total integral 1, there are two possible generators, depending on the orientation of the fiber. A priori all that one could say is that $\left[\sigma_{a}\right]= \pm\left[\sigma_{\beta}\right]$ on $U_{a} \cap U_{B}$. For an orientable sphere bundle either choice of a consistent system of generators is called an orientation of the sphere bundle. A bundle with a given orientation is said to be oriented. An $S^{0}$-bundle over a manifold $M$ is a double cover of $M$; such a bundle over a connected base space is said to be orientable if and only if the total space has two connected components.

Caveat. The fact that the cohomology classes $\left\{\left[\sigma_{a}\right]\right\}$ agree on overlaps does not mean that they piece together to form a global cohomology class. A global cohomology class must be represented by a global form; the equality of cohomology classes $\left[\sigma_{\alpha}\right]=\left[\sigma_{\beta}\right]$ implies only that the forms $\sigma_{\alpha}$ and $\sigma_{\beta}$ differ by an exact form.

Recall that in Section 7 we called a vector bundle of rank $n+1$ orientable if and only if it can be given by transition functions with values in $S O(n+1)$. We now study the relation between the orientability. of a sphere bundle and the orientability of a vector bundle.

Let $E$ be a vector bundle of rank $n+1$ endowed with a Riemannian metric so that its structure group is reduced to $O(n+1)$. Its unit sphere bundle $S(E)$ is the fiber bundle whose fiber at $x$ consists of all the unit vectors in $E_{x}$ and whose transition functions are the same as those of $E$. $S(E)$ is an $S^{\mathbf{m}}$-bundle with structure group $O(n+1)$.

Remark 11.1. Fix an orientation on the sphere $S^{n}$. If the linear transformation $g$ is in the special orthogonal group $S O(n+1)$ and $[\sigma]$ is a
generator of $H^{\prime \prime}\left(S^{\prime \prime}\right)$ with $\int_{s_{0}} \sigma=1$, then the image $g\left(S^{\prime \prime}\right)$ is the sphere $S^{n}$ with the same orientation, so that

$$
\int_{J^{\prime}} g^{*} \sigma=\int_{\sigma^{*}} \sigma=\int_{s^{*}} \sigma=1 .
$$

Thus for an orthogonal transformation $g, g^{*} \sigma$ and $\sigma$ represent the same cohomology class if and only if $g$ has positive determinant.

Proposition 11.2. A vector bundle $E$ is orientable if and only if its sphere bündle $S(E)$ is orientable.

Proor. $(\Rightarrow)$ Fix a generator $\sigma$ on $S^{m}$ and fix a trivialization $\left\{\left(U_{n}, \phi_{a}\right)\right\}$ for $E$ so that the transition functions $g_{c}$ assume values in $S O(n+1)$. Let

$$
\rho_{a}: U_{a} \times S^{m} \rightarrow S^{m}
$$

be the projection and let $\pi^{-1}(x)$ be the fiber of the sphere bundil $\pi: S(E) \rightarrow M$ at $x$. Define $\left[\sigma_{\alpha}\right]$ in $H^{m}\left(\left.S(E)\right|_{u_{0}}\right)$ by

$$
\left[\sigma_{\alpha}\right]=\phi_{E}^{*} \rho_{\alpha}^{*}[\sigma]
$$

To avoid cumbersome notations we will write $\left.\left[\sigma_{d}\right]\right|_{x}$ and $\left.\phi_{a}\right|_{x}$ for the re-

$$
\left.\left[\sigma_{e}\right]\right|_{x}=\left(\left.\phi_{\varepsilon}\right|_{x}\right)^{*}[\sigma]
$$

It follows that if $x \in U_{E} \cap U_{A}$, then

$$
\begin{aligned}
{\left.\left[\sigma_{A}\right]\right|_{x} } & =\left(\left.\phi_{A}\right|_{x}\right)^{*}[\sigma] \\
& =\left.\left(\left.\phi_{A}\right|_{x}\right)^{*}\left(\left(\left.\phi_{A}\right|_{x}\right)^{*}\right)^{-1}\left[\sigma_{\alpha}\right]\right|_{x} \\
& =\left.g_{\mu}(x)^{*}\left[\sigma_{\alpha}\right]\right|_{x} \\
& =\left.\left[\sigma_{\alpha}\right]\right|_{x},
\end{aligned}
$$

since $g_{a f}(x)$ has positive determinant. Therefore, $\left[\sigma_{\beta}\right]=\left[\sigma_{e}\right]$ on $U_{a} \cap U_{A}$ and the sphere bundle $S(E)$ is orientable.
$(\leftarrow)$ Conversely, let $\left\{U_{\alpha},\left[\sigma_{\alpha}\right]\right\}$ be an orientation on the sphere bundle $S(E)$ and let $\left(S^{n}, \sigma\right)$ be an oriented sphere in $R^{n+1}$, where $\sigma$ is a nontrivial top form on $S^{\boldsymbol{n}}$. Choose the trivializations for $S(E)$

$$
\phi_{\varepsilon}:\left.S(E)\right|_{v_{\varepsilon}} \stackrel{\sim}{\rightarrow} U_{\varepsilon} \times S^{n}
$$

in such a way that $\phi_{\mathrm{A}}$ preserves the metric and $\phi_{c}^{*} \rho_{e}^{*}[\sigma]=\left[\sigma_{\alpha}\right]$. Then at any point $x$ in $U_{\mu} \cap U_{\beta}$, the transition function $g_{a d}(x)$ pulls [ $\sigma$ ] to itelf and $s o$ $g_{\text {af }}(x)$ must be in $S O(n+1)$.

Remark 11.3. Since $S O(1)=\{1\}$, a line bundle $L$ over a connected base space is orientable if and only if it is trivial: In this case the sphere bundle $S(L)$ ponsists of two connected components. ":

Proposition 11.4. $A$ vector bundle $E$ is orientable if and only if its determinant bundle det $E$ is orientable.

Proof. Let $\left\{g_{\alpha \beta}\right\}$ be the transition functions of $E$. Then the transition functions of det $E$ are $\left\{\operatorname{det} g_{a f}\right\}$. An orthogonal matrix $g_{a p}$ assumes values in $S O(n+1)$ if and only if det $g_{a f}$ is positive, so the proposition follows.

Whether $E$ is orientable or not, the 0 -sphere bundle $S($ det $E)$ is-always a 2 -sheeted covering of $M$. Combining Corollary 11.3 and Proposition 11.4, we see that over a connected base space a vector bundle $E$ is orientable if and-only if $S($ det $E$ ) is disconnected. Since a simply connected base space cannot have any connected covering space of more than one sheet, we have proven the following.

Proposition 11.5. Every vector bundle over a simply connected base space is orientable.

In particular, the tangent bundle of a simply connected manifold is orientable. Since a manifold is orientable if and only if its tangent bundie is (Example 6.3), this gives

Corollary 11.6. Every simply connected manifold is orientable.

## The Euler Class of an Oriented Sphere Bundle

We first consider the case of a circle bundle $\pi: E \rightarrow M$ with structure group . Diff( $S^{1}$ ). As stated in the introduction to this section, our problem is to find a closed global 1 -form on $E$ which restricts to a generator of the cohomology on each fiber. As a first approximation, in each $U_{\text {a }}$ of a good cover $\left\{U_{\alpha}\right\}$ of $M$ we choose a generator $\left[\sigma_{0}\right]$ of $H^{1}\left(E \mid u_{0}\right)$. The collection $\left\{\sigma_{\varepsilon}\right\}$ is an element $\sigma^{0.1}$ in the double complex $C^{*}\left(\pi^{11} \mathbf{U}, \Omega^{*}\right)$ :

From the isomorphism between the cohomology of $E$ and the cohomology of this double complex,

$$
H_{b x}(E) \simeq H_{D}\left\{C^{\star}\left(\pi^{-1} \mathbb{U}, \Omega^{*}\right)\right\},
$$

we see that to find a global form which restricts to the d-cohomology class of $\sigma^{0,1}$ it suffices to extend $\sigma^{0,1}$ to a $D$-cocycle. The first step of the extension requires that $\left(\delta \sigma^{0,1}\right)_{a \rho}=\sigma_{\beta}-\sigma_{a}$ be exact, Y.e., $\left[\sigma_{d}\right]=\left[\sigma_{\beta}\right]$ for all $a_{3} \beta$.

This is precisely the orientability condition. Assume the bundle $E$ to be oriented with orientation $\sigma^{0.1}$, so that $\delta \sigma^{0.1}=d \sigma^{1.0}$ for some $\sigma^{1,0}$ in $C^{1}\left(\pi^{-1} \mathcal{U}, \Omega^{0}\right)$. Then $\sigma^{0,1}+\sigma^{1,0}$ is a $D$-cocycle if and only if $\delta \sigma^{1,0}=0$. Since

$$
d\left(\delta \sigma^{1,0}\right)=\delta\left(d \sigma^{1,0}\right)=\delta\left(\delta \sigma^{0.1}\right)=0
$$

$\delta \sigma^{1,0}$ actually comes from an element $-\varepsilon$ of the cochain group $C^{2}\left(\pi^{-1} u\right.$, $\mathbb{R}$ ). Now since the open covers $\mathfrak{U}$ and $\pi^{-1} \mathfrak{U}$ have the same combinatorics, i.e., $\pi^{-1} U_{a 0 \ldots \alpha_{p}}$ is nonempty if and only if $U_{a_{0} \ldots \alpha_{p}}$ is, $C^{*}\left(\pi^{-1} \mathfrak{U}, \mathbf{R}\right)=C^{*}(\mu, R)$ and we may regard $\varepsilon$ as an element of $C^{2}(\mathfrak{U}, R)$. In fact, because $\delta \varepsilon=0, \varepsilon$ defines a Cech cohomology class in $H^{2}(\mathfrak{U}, \mathrm{R})$. By the isomorphism between the Cech cohomology of a good cover and de Rham cohomology, $\varepsilon$ corresponds to a cohomology class $e(E)$ in $H^{2}(M)$. For a circle bundle with structure group SO(2), this class turns out to be the Euler class of Section 6, as will be shown later. So for an oriented circle bundle $E$ with structure group Diff( $S^{i}$ ) we also call $e(E)$ the Euler class.

The discussion above generalizes immediately to any sphere bundle with fiber $S^{n}, n \geq 1$. Such a sphere bundle is orientable if and only if it is possible to find an element $\sigma^{0, n}$ in $C^{0}\left(\pi^{-1} \mathfrak{U}, \Omega^{\prime \prime}\right)$ which extends one step down toward being a $D$-cocycle:

$$
\delta \sigma^{0, n}=d \sigma^{1, n-1}=-D^{n} \sigma^{1, n-1}
$$

There is no obstruction to extending $\sigma^{1 . n-1}$ one step further, since every closed ( $n-1$ )-form on $\left.E\right|_{U_{n 0, a 1, .2}}$ is exact. In general, extension is possible until we hit a nontrivial cohomology of the fiber. Thus for an oriented sphere bundle $E$ we can extend all the way down to $\sigma^{n, 0}$ in such a manner that if

$$
\sigma=\sigma^{0, n}+\sigma^{1, n-1}+\cdots+\sigma^{n, 0},
$$

then

$$
D \sigma=\delta \sigma^{n, 0}
$$

,

Since $d\left(\delta \sigma^{n, 0}\right)=\delta\left(d \sigma^{n, 0}\right)= \pm \delta\left(\delta \sigma^{n-1,1}\right)=0$,

$$
D \sigma=\delta \sigma^{\mathrm{n}, 0}=i(-\varepsilon)
$$

for some $\varepsilon$ in $C^{n+1}\left(\pi^{-1} u, R\right) \simeq C^{+1}(u, R)$, where $i$ is the inclusion $C^{n+1}(\mathcal{U}, R) \rightarrow C^{n+1}\left(u, \Omega^{0}\right)$. Clearly $\delta \varepsilon=0$, so 8 defines a cohomology clase $e(E)$ in $H^{n+1}(4, R) \simeq H^{n+1}(M)$, the Euler class of the oriented $S^{0}$-bundle. $E$
with orientation $\sigma^{0, n}$. The Euler class of an oriented $S^{0}$-bundle is defined to be 0 . Note that the Euler class depends on the orientation $\left\{\left[\sigma_{a}\right]\right\}$ of $E$; the opposite orientation would give $-e(E)$ instead.

If $E$ is an oriented vector bundle, the complement $E^{0}$ of its zero section has the homotopy type of an oriented sphere bundle. The Euler class of $E$ is defined to be that of $E^{0}$. Equivalently, if $E$ is endowed with a Riemannian metric, then the unit sphere bundle $S(E)$ of $E$ makes sense and we may define the Euler class of $E$ to be that of its unit sphere bundle. This latter definition is independent of the metric and in fact agrees with the definition in terms of $E^{0}$, since for any metric on $E$, the unit sphere bundle $S(E)$ has the homotopy type of $E^{0}$.

In the next two propositions we show that the Euler class is well defined.
Proposition 11.7. For a given orientation $\left\{\left[\sigma_{a}\right]\right\}$ the Euler class is independent of the choice of $\sigma^{j, n-j}, j=1, \ldots, n$.

Proof.

Let $\bar{\sigma}^{0, n}$ be another cochin in $C^{0}\left(\pi^{-1} \mathfrak{U}, \Omega^{n}\right)$ which represents the orinstation $\left\{\left[\sigma_{\alpha}\right]\right\}$. Then $\tilde{\sigma}^{0, n}-\sigma^{0, n}=d \tau^{n-1}$ for some $\tau^{n-1}$ in $C^{0}\left(\pi^{-1} \mathfrak{U}, \Omega^{n-1}\right)$. Since $d\left(\delta \tau^{n-1}\right)$ and $d\left(\bar{\sigma}^{1, n-1}-\sigma^{1, n-1}\right)$ are equal, $\delta \tau^{n-1}$ and $\bar{\sigma}^{1, n-1}-\sigma^{1, n-1}$ differ by $d \tau^{n-2}$ for some $\tau^{-2}$ in $C^{1}\left(\pi^{-1} \mathfrak{U}, \Omega^{n-2}\right)$. Again,
so

$$
\begin{gathered}
d\left(\delta \tau^{n-2}\right)=-d\left(\partial^{2, n-2}-\sigma^{2, n-2}\right) \\
\left(\delta \tau^{n-2}\right)-\left(\bar{\sigma}^{2, n-2}-\dot{k}^{2, n-2}\right)=d \tau^{n-3}
\end{gathered}
$$

$\square$
for some $\tau^{n-3}$ in $C^{2}\left(\pi^{-1} \mathfrak{u}, \Omega^{n-3}\right)$. Eventually we get

$$
\delta \tau^{0}-\left(\bar{\sigma}^{n, 0}-\sigma^{\pi, 0}\right)=i \tau, \tau \in C^{7}\left(\pi^{-1} u, R\right) .
$$

Taking $\delta$ of both sides, we have ${ }^{\prime}$

$$
\bar{\varepsilon}-\varepsilon=\delta \tau
$$

So $\bar{\varepsilon}$ and $\varepsilon$ define the same mech cohomology class.

Proposition 11.8. The Euler class $e(E)$ is independent of the choice of the good cover.

Proof. Write $\varepsilon_{u}$ for the cocycle in $H^{n+1}(\mathcal{U}, \mathbb{R})$ which defines the Euler class in terms of the good cover $\mathcal{U}$. If a good cover $\mathfrak{B}$ is a refinement of $\mathbb{U}$, then there is a commutative diagram

$\varepsilon_{u}$ and $\varepsilon_{\vartheta}$ give the same element in $H_{D R}^{n+1}(M)$, because if we choose the $\sigma^{0, n}$ on $\pi^{-1} \mathfrak{B}$ to be the restriction of the $\sigma^{0, n}$ on $\pi^{-1} \mathfrak{U}$, the cocycle $\varepsilon_{\mathfrak{g}}$ in $C^{n+1}(\mathfrak{B}$, $\mathbb{R}$ ) will be the restriction of the cocycle $\varepsilon_{\mathfrak{u}}$ in $C^{n+1}(\mathfrak{u}, \mathbb{R})$, so that as elements of the Cech cohomology $H^{n+1}(M, R)$ they are equal. Given two arbitrary good covers $\mathfrak{U}$ and $\mathfrak{B}$, we can take a common refinement $\mathfrak{W}$; then $\varepsilon_{\mathbb{U}}=$ $\varepsilon_{\boldsymbol{W}}=\varepsilon_{i \mathrm{ij}}$ in $H^{n+1}(M, R)$. So the Euler class is independent of the cover.

If the Euler class vanishes, then the $D$-cocycle $\sigma$ corresponds to a global form which restricts to the $d$-cohomology class of $\sigma^{0, n}$. In sum, then, there is a global form that restricts to a generator on each fiber if and only if
(a) $E$ is orientable, and
(b) the Euler class $e(E)$ vanishes.

For $E$ a product bundle, the extension stops at the $\sigma^{0.0}$ stage so that $\varepsilon=0$. In this sense the Euler class is a measure of the twisting of an oriented sphere bundle. However, as we will see in the proposition below, $E$ need not be a product bundle for its Euler class to vanish.

Proposition 11.9. If the oriented sphere bundle E has a section, then its. Euler class vanishes.

Proof. Let $s$ be a section of $E$. It follows from $\pi \circ s=1$ that $s^{*} \pi^{*}=1$. We saw in the construction of the Euler class that

$$
-\pi^{*} \varepsilon=D \sigma
$$

for some $D$-cochain $\sigma$. Applying $s^{*}$ to both sides gives

$$
-\varepsilon=D s^{*} \sigma_{0}
$$

so $e$ is a coboundary in $H^{*}(M)$.

The converse of this proposition is not true. In general a cohomology class' is too "coarse" an invariant to yield information' on the existence of geometrical constructs. In (23.16) we will show the existence of a sphere bundle whose Euler class vanishes, but which does not admit any section."

We now show that for a circle bundle $\pi: E \rightarrow M$ with structure group $S O(2)$ the definitions of the Euler class in Section 6 and in this section agree. We briefly recall here the earlier construction. If $\theta_{\alpha}$ is the angular coordinate over $U_{\alpha}$, then $\left[d \theta_{\alpha} / 2 \pi\right]$ is a generator of $H^{1}\left(\left.E\right|_{v_{j}}\right)$. Furthermore,

$$
\frac{d \theta_{\beta}}{2 \pi}-\frac{d \theta_{\alpha}}{2 \pi}=\pi^{*} \frac{d \phi_{\alpha \beta}}{2 \pi}=\pi^{*} \xi_{\beta}-\pi^{*} \xi_{\alpha} \text { for some } 1 \text {-form } \xi_{\alpha} \text { over } U_{\alpha} .
$$

The Euler class of the circle bundle $E$ was defined to be the cohomology class of the global form $\left\{d \xi_{\alpha}\right\}$.

In the present context these cochains fit into the double complex $C^{*}\left(\pi^{-1} \mathfrak{U}, \Omega^{*}\right)$ of $E$ as shown in the diagram below.

$$
C^{*}\left(\pi^{-1} \mathfrak{u}, \mathbb{R}\right)
$$

By the explicit isomorphism between de Rham and Cech (Proposition 9.8), the differential form on $M$ corresponding to the Cech cocycle $\varepsilon$ is $\left(-D^{\prime \prime} K\right)^{2} \varepsilon$. Since $\xi_{\beta}-\xi_{\alpha}=(1 / 2 \pi) d \phi_{a \beta}, \delta \xi=(1 / 2 \pi) d \phi$, so by (8.7), we may take $\xi$ to be $(1 / 2 \pi) K d \phi$. Also note that since $\delta(\phi / 2 \pi)=-\varepsilon$,

$$
-K \varepsilon=\phi / 2 \pi \text { (modulo a } \delta \text {-coboundary). }
$$

Hence

$$
\begin{aligned}
\left(-D^{\prime} K\right)^{2} \varepsilon & =-d K d K \varepsilon \\
& =d K d((\phi / 2 \pi)+\delta \tau) \text { for some } \tau \\
& =d K d(\phi / 2 \pi)+d K d \delta \tau \\
& =d \xi+d K d \delta \tau .
\end{aligned}
$$

Here

$$
\begin{aligned}
d K d \delta \tau & =d K \delta d \tau & & \text { because } d \text { commutes with } \delta \\
& =d(1-\delta K) d \tau & & \text { by }(8.7) \\
& =-\delta d K d \tau . & &
\end{aligned}
$$

Since $K d \tau \in \Omega^{1}(M), d K d \tau$ is a global exact form, so $\delta d K d \tau=0$. Hence $\left(-D^{\prime \prime} K\right)^{2} \varepsilon=d \xi$, showing that the two definitions of the Euler class could be made to agree on the level of forms.

## The Global Angular Form

In Section 6 we exhibited on an oriented circle bundle the global angular form $\psi$ which has the following properties:
(a) its restriction to each fiber is a generator of the cohomology of the fiber;
(b) $d \psi=-\pi^{*} e$, where $e$ represents the Euler class of the circle bundle.

Using the collating formula (9.5) we will now construct such a form on any oriented $S^{n}$-bundle.

Let $\mathfrak{U}=\left\{U_{a}\right\}$ be an open cover of $M$. Recall that the Euler class of $E$ is defined by the following diagram:

where $\alpha_{0} \in C^{0}\left(\pi^{-i} \mathfrak{U}, \Omega^{\prime \prime}\right)$ is the orientation of $E$,

$$
\delta \alpha_{i}=-D^{n} \alpha_{i+1}, \quad i=0, \ldots, n-1
$$

and

$$
\delta \alpha_{n}=-\pi^{\star \epsilon} \varepsilon
$$

Hence

$$
D\left(\alpha_{0}+\cdots+\alpha_{n}\right)=-\pi^{*} \varepsilon .
$$

Here $\alpha_{i}$ is what we formerly wrote as $\sigma^{d, n-1}$.
If $\left\{\rho_{\alpha}\right\}$ is a partition of unity subordinate to the open cover $\mathfrak{U}=\left\{U_{\alpha}\right\}$, then $\left\{\pi^{*} \rho_{a}\right\}$ is a partition of unity subordinate to the inverse cover $\pi^{-1} \mathfrak{u}=$ $\left\{\pi^{-1} U_{a}\right\}$. Using these data we can define a homotopy operator $K$ on the double complex $C^{*}\left(\mathfrak{U}, \Omega^{*}\right)$ and also one on $C^{*}\left(\pi^{-1} \mathfrak{U}, \Omega^{*}\right)$ as in (8.6). We denote both operators by $K$. Both $K$ satisfy

$$
\delta K+K \delta=1
$$

Since

$$
\begin{aligned}
\left(K \pi^{*} \omega\right)_{a_{0} \ldots a_{p-1}} & =\sum\left(\pi^{*} \rho_{\mu}\right)\left(\pi^{*} \omega\right)_{a_{0} \ldots a_{p-1}} \\
& =\pi^{*} \sum \rho_{a} \omega_{a_{0} \ldots \varepsilon_{p-1}} \\
& =\left(\pi^{*} K \omega\right)_{a_{0} \ldots \alpha_{p-1}},
\end{aligned}
$$

$K$ commutes with $\boldsymbol{\pi}^{*}$.

Exercise 11.10. If $s: M \rightarrow E$ is a section, show that $K s^{*}=s^{*} K$.
By the collating formula (9.5),

$$
\begin{equation*}
\psi=\sum_{i=0}^{n}(-1)^{\prime}\left(D^{\prime \prime} K\right)^{i} \alpha_{i} \quad+(-1)^{n+1} K\left(D^{\prime \prime} K\right)^{n}\left(-\pi^{*} \varepsilon\right) \tag{11.11}
\end{equation*}
$$

is a global form on $E$. Furthermore,

$$
\begin{align*}
d \psi & =(-1)^{n+1} \cdot d K\left(D^{\prime \prime} K\right)^{n}\left(-\pi^{*} \varepsilon\right) \\
& =-\pi^{*}(-1)^{n+1}\left(D^{\prime \prime} K\right)^{n+1} \varepsilon \text { since } \pi^{*} \text { commutes with } D^{\prime \prime} K \\
& =-\pi^{*} e . \text { by Proposition } 9.8 . \tag{11.12}
\end{align*}
$$

In formula (11.11) since the restriction of $\pi^{*}\left((-1)^{n+1} K\left(D^{\prime \prime} K\right)^{n} \varepsilon\right)$ to a fiber is 0 , the restriction of the global form $\psi$ to each fiber is $d$-cohomologous to $\left.\alpha_{0}\right|_{\text {fiber }}$, hence is a generator of the cohomology of the fiber. The gobal $n$-form $\psi$ on the sphere bundle $E$ satisfies the properties (a) and (b) stated earlier. We call it the global angular form on the sphere bundle.

Exercise 11.13. Use the existence of the global angular form $\psi$ to prove Proposition 11.9.

## Euler Number and the Isolated Singularities of a Section

Let $\pi: E, M$ be an oriented $(k-1)$-sphere bundle over a compact oriented manifold of dimension $k$. Since $H^{k}(M) \simeq \mathbb{P}$, the Euler class of $E$ may be identified with the number $\int_{M} e(E)$, which is by definition the Euler number of $E$. The Euler number of the manifold $M$ is defined to be that of its unit tangent bundle $S\left(T_{M}\right)$ relative to some Riemannian structure on $M$. While the Euler number of an orientable sphere bundle is defined only up to sign, depending on the orientations of both $E$ and $M$, the Euler number of the orientable manifold $M$ is unambiguous, since reversing the orientation of $M$ also reverses that of the tangent bundle.

In general the sphere bundle $E$ will not have a global section; however, there may be a section $s$ over the complement of a finite number of points $x_{1}, \ldots, x_{q}$ in $M$. In fact, as we will show in Proposition 11.14, if the sphere bundle has structure group $O(k)$, then such a "partial" section $s$ always exists. In this section we will explain how one may compute the Euler class of $E$ in terms of the behavior of the section $s$ near the singularities $x_{1}, \ldots, x_{q}$.

Proposition 11.14. Let $\pi: E \rightarrow M$ be a $(k-1)$-sphere bundle over a compact manifold of dimension $k$. Suppose the structure group of $E$ can be reduced to $O(k)$. Then $E$ has a section over $M-\left\{x_{1}, \ldots, x_{q}\right\}$ for some finite number of points in $M$.

Proof. Since the structure group of $E$ is $O(k)$, we can form a Riemannian vector bundle $E^{\prime}$ of rank $k$ whose unit sphere bundle is $E$. A section $s^{\prime}$ of $E^{\prime}$ over $M$ gives rise to a partial section $s$ of $E: s(x)=s^{\prime}(x) /\left\|s^{\prime}(x)\right\|$, where \| \| denotes the length of a vector in $E^{\prime}$. Let $Z$ be the zero locus of $s^{\prime} ; s$ is only a partial section in the sense that it is not defined over $Z$. Thus to prove the proposition, we only have to show that the vector bundle $E^{\prime}$ has a section that vanishes over a finite number of points.

This is an easy consequence of the transversality theorem which states that given a submanifold $Z$ in a manifold $Y$, every map $f: X \rightarrow Y$ becomes transversal to $Z$ under a slight perturbation (Guillemin and Pollack [1, p. 68]). Furthermore, we may assume that a small perturbation of a section of $E$ is again a section, as follows. Suppose $f$ is a perturbation of $s$ and $f$ is transversal to the zero section. Then $g=\pi \circ f$ is a perturbation of $\pi \circ s$, which is the identity. Thus, for a sufficiently small perturbation, $g$ will be close to the identity and so must be a diffeomorphism. For such an $f$, define $s^{\prime}(x)=f\left(g^{-1}(x)\right)$. Then $\pi \circ s^{\prime}=1$ and $s^{\prime}$ is transversal to the zero section $s_{0}$, i.e., $S=s^{\prime}(M)$ intersects $S_{0}=s_{0}(M)$ transversally. Since

$$
\operatorname{dim} S+\operatorname{dim} S_{0}=\operatorname{dim} E^{\prime},
$$

$S \cap S_{0}$ consists of a discrete set of points. By the compactness of $S_{2}$, it must be a finite set of points.

Remark 11.15. It follows from the rudiments of obstruction theory that this proposition is true even if the structure group of the sphere bundle cannot be reduced to an orthogonal group. For a beautiful account of obstruction theory, see Steenrod [1, Part III].: :

Suppose $s$ is a section over a punctured neighborhood of a point $x$ in $M$. Choose this neighborhood sufficiently small so that it is diffeomorphic to a punctured disc in $\mathbb{R}^{k}$ and $E$ is trivial over it. Let $D_{r}$ be the open neighborhood of $x$ corresponding to the ball of radius $r$ in $\mathbb{R}^{k}$ under the diffeomorphism above. As an open subset of the oriented manifold $M, D_{r}$ is also oriented. Choose the orientation on the sphere $S^{k-1}$ in such a way that the isomorphism $\left.E\right|_{D_{r}} \simeq D_{r} \times S^{k-1}$ is orientation-preserving, where $D_{r} \times S^{k-1}$ is given the product orientation. (If $A$ and $B$ are two oriented manifolds with orientation forms $\omega_{A}$ and $\omega_{B}$, then the product orientation on $A \times B$ is given by $\left(p_{1}^{*} \omega_{A}\right) \wedge\left(p_{2}^{*} \omega_{B}\right)$, where $p_{1}$ and $p_{2}$ are the projections of $A \times B$ onto $A$ and $B$ respectively.) The local degree of the section $s$ at $x$ is defined to be the degree of the composite map

$$
\left.\partial \bar{D}_{r} \stackrel{n}{\rightarrow} E\right|_{D_{r}}=\bar{D}_{r} \times S^{k-1} \xrightarrow[\rightarrow]{\bullet} S^{k-1} \quad \cdots
$$

where $\rho$ is the projection and $\bar{D}_{r}$ is the closure of $D_{r}$.

Theorem 11.16. Let $\pi: E \rightarrow M$ be an oriented ( $k-1$ )-sphere bundle over a compact oriented manifold of dimension $k$. If $E$ has a section over $M-\left\{x_{1}\right.$, $\left.\ldots, x_{q}\right\}$, then the Euler number of $E$ is the sum of the local degrees of $s$ at $x_{1}, \ldots, x_{i}$.

Proof. Let $M_{r}$ be $M$ minus the balls of radius $r$ around the points $x_{1}, \ldots$, $x_{q}$. (By the radius, we mean the radius in $\mathbb{R}^{n}$ under some fixed diffeomorphisms of the neighborhoods of the singular points $x_{1}, \ldots, x_{q}$ as above.) The Euler number of $E$ is

$$
\begin{align*}
& \int_{M} e=\lim _{r \rightarrow 0} \int_{M_{r}} e=\lim _{r \rightarrow 0} \int_{M_{r}} s^{*} \pi^{*} e \quad \text { since } s \text { is a global section }  \tag{11.16.1}\\
& \text { over } M_{\text {, }} \\
& =-\lim _{r \rightarrow 0} \int_{\boldsymbol{M}_{r}} s^{*} d \psi \quad \text { because } \pi^{*} e=-d \psi \\
& =-\lim _{r \rightarrow 0} \int_{\text {OM, }} s^{*} \psi \quad \text { by Stokes' theorem. }
\end{align*}
$$

For each $i$, choose an open ball $D_{r}$ around the singularity $x_{i}$ as before. (To keep the notation simple, we write $D_{r}$ rather than $D_{r, i}$.) Let $\sigma$ the generator of $S^{k-1}$. Then $\rho^{*} \sigma$ restricts to the generator on each fiber of $\left.E\right|_{D_{r}}$. So $\rho^{*} \sigma$ and the angular form $\psi$ define the same cohomology class in $H^{*}\left(\left.E\right|_{D_{r}}\right)$, i.e.,

$$
\psi-\rho^{*} \sigma=d \tau
$$

for some ( $k-2$ )-form $\tau$ on $\left.E\right|_{D_{r}}$. By shrinking $r$ slightly, we may assume that $\tau$ is defined over a neighborhood of the closed ball $\bar{D}_{r}$. Then

$$
s^{*} \psi-s^{*} \rho^{*} \sigma=s^{*} d \tau
$$

and

$$
\int_{\Delta D_{r}} s^{*} \psi-\int_{0 D_{r}} s^{*} \rho^{*} \sigma=\int_{0 D_{r}} d s^{*} \tau=0 \quad \text { by Stokes' theorem. }
$$

Therefore,

$$
\int_{0 \text { Dit }_{r}} s^{*} \psi=\text { local degree of the section } s \text { at } x_{1}
$$

Since $\partial \bar{D}_{r}$ has the opposite orientation as $\partial M_{r}$,

$$
-\lim _{r \rightarrow 0} \int_{o M_{r}} s^{*} \psi=\lim _{r \rightarrow 0} \sum_{x_{i}} \int_{\partial D_{r}} s^{*} \psi=\sum_{i} \text { (local degree of } s \text { at } x_{i} \text { ). }
$$

Together with (11.16.1), this gives

$$
\int_{M} e=\sum_{i}\left(\text { local degree of } s \text { at } x_{i}\right) .
$$

This theorem can also be phrased in terms of vector bundles. Let $\pi: E \rightarrow M$ be an oriented rank $k$ vector bundle over a manifold of dimension $k$ and $s$ a section of $E$ with a finite number of zeros. The multiplicity of a zero $x$ of $s$ is defined to be the local degree of $x$ as a singularity of the section $s /\|s\|$ of the unit sphere bundle of $E$ relative to some Riemannian structure on $E$. (This definition of the index is independent of the Riemannian structure because the local degree is a homotopy invariant.) Since the Euler class $e(E)$ of $E$ is a $k$-form on $M$, it is Poincaré dual to $n P$, where ${ }^{*}$ $n=\int_{M} e(E)$ and $P$ is a point on $M$. Thus we have the following.

Theorem 11.17. Let $\pi: E \rightarrow M$ be an oriented rank $k$ vector bundle over a compact oriented manifold of dimension $k$. Let $s$ be a section of $E$ with a finite number of zeros. The Euler class of $E$ is Poincaré dual to the zeros of $\&$ counted with the appropriate multiplicities.

Example 11.18 (The Euler class of the unit tangent bundle to $S^{2}$ ). Let $S\left(T_{s_{2}}\right)$ be the unit tangent bundle to $S^{2}$. It is a circle bundle over $S^{2}$ :

Fix a unit tangent vector $v$ at the north pole. We can define a smooth vector field on $\boldsymbol{S}^{\mathbf{2}}$-\{south pole\} by parallel translating $v$ along the great circles from the north pole to the south pole (see Figure 11.1). (Parallel translation along a great circle on $S^{2}$ is prescribed by the following two conditions:
(a) the tangent field to the great circle is parallel;
(b) the angles are preserved under parallel translation.)

Figure 11.1

Figure 11.2
This gives a section $s$ of $S\left(T_{s^{2}}\right)$ over $S^{2}$-\{south pole\}. On a small circle around the south pole, the vector field looks like Figure 11.2, i.e., as we go around the circle $90^{\circ}$, the vectors rotate through $180^{\circ}$; therefore, the local degree of $s$ at the south poie is 2. By Theorem 11.16, the Euler class of the unit tangent bundle to $S^{2}$ is 2 .

Exercise 11.19. Show that the Euler class of an oriented sphere bundle with even-dimensional fibers is zero, at least when the sphere bundle comes from a vector bundle.

Since the Euler class is the obstruction to finding a closed global angular form on an oriented sphere bundle, by the Leray-Hirsch theorem we have the following corollary of Exercise 11.14.

Proposition 11.20. If $\pi: E \rightarrow M$ is an orientable $S^{2 n}$-bundle, then

$$
H^{*}(E)=H^{*}(M) \otimes H^{*}\left(S^{2 n}\right) .
$$

Exercise 17.21. Compute the Euler class of the unit tangent bundle of the sphere ' $S^{k}$ by finding a vector field on $S^{k}$ and computing its local degrees.

## Euler Characteristic and the Hopf Index Theorem

In this section we show that the Euler number $\int_{M} e\left(T_{M}\right)$ is the same as the Euler characteristic $\chi(M)=\sum(-1)^{9} \operatorname{dim} H^{9}(M)$ and deduce as a corollary the Hopf index theorem. The manifold $M$ is assumed to be compact and oriented.

Let $\left\{\omega_{i}\right\}$ be a basis of the vector space $H^{*}(M),\left\{\tau_{j}\right\}$ be the dual basis under Poincaré duality, i.e., $\int_{M} \omega_{i} \wedge \tau_{j}=\delta_{i j}$, and let $\pi$ and $\rho$ be the two projections of $M \times M$ to $M$ :

By the Künneth formula, $H^{*}(M \times M)=H^{*}(M) \otimes H^{*}(M)$ with $\left\{\pi^{*} \omega_{i}{ }^{*} \wedge\right.$ $\left.\rho^{*} \tau_{j}\right\}$ as an additive basis. So the Poincare dual $\eta_{\Delta}$ of the diagonal $\Delta$ in $M \times M$ is some linear combination $\eta_{\Delta}=\sum c_{i j} \pi^{*} \omega_{i} \wedge \rho^{*} \tau_{j}$.

Lemma 11.22. $\eta_{\Delta}=\sum(-1)^{\operatorname{deg} \omega_{i}} \pi^{*} \omega_{i} \wedge \rho^{*} \tau_{i}$.
Proof. We compute $\int_{\Delta} \pi^{*} \tau_{k} \wedge \rho^{*} \omega_{1}$ in two ways. On the one hand, we can pull this integral back to $M$ via the diagonal map $t: M \rightarrow \Delta \subset M \times M$ :

$$
\int_{\Delta} \pi^{*} \tau_{k} \wedge \rho^{*} \omega_{l}=\int_{M} \iota^{*} \pi^{*} \tau_{k} \wedge \imath^{*} \rho^{*} \omega_{i}=\int_{M} \tau_{k} \wedge \omega_{l}=(-1)^{\left(\operatorname{deg} r_{i}\right)\left(\operatorname{deg} \omega_{l}\right)} \delta_{k l}
$$

On the other hand, by the definition of the Poincare dual of a closed oriented submanifold (5.13),

Therefore

$$
c_{k l}= \begin{cases}0 & \text { if } k \neq l \\ (-1)^{\operatorname{deg} \omega_{k}} & \text { if } k=l .\end{cases}
$$

Lemma 11.23. The normal bundle $N_{\Delta}$ of the diagonal $\Delta$ in $M \times M$ is isomorphic to the tangent bundle $T_{\Delta}$.

Proof. Since the diagonal map $t: M \times M$ sends $M$ diffeomorphically onto $\Delta, l^{*} T_{\Delta}=T_{M}$. It follows from the commutative diagram

$$
\begin{aligned}
(v, v) & \mapsto(v, v) \\
0 \rightarrow T_{\Delta} & \left.\rightarrow T_{M \times M}\right|_{\Delta} \rightarrow N_{\Delta} \rightarrow 0 \\
R & \cdots \| \\
0 \rightarrow & T_{M} \rightarrow T_{M} \oplus T_{M} \rightarrow T_{M} \rightarrow 0 \\
v & \mapsto(v, v)
\end{aligned}
$$

that $N_{\Delta} \simeq T_{M} \simeq T_{\Delta}$.

$$
\begin{aligned}
& \int_{\Delta} \pi^{*} \tau_{k} \wedge \rho^{*} \omega_{l}=\int_{M \times M} \pi^{*} \tau_{k} \wedge \rho^{*} \omega_{l} \wedge \eta_{\Delta} \\
& =\sum_{i, j} c_{i j} \int_{M \times M} \pi^{*} \tau_{k} \wedge \rho^{*} \omega_{l} \wedge \pi^{*} \omega_{i} \wedge \rho^{*} \tau_{j} \cdot: \\
& =\sum_{i, j} c_{i j}(-1)^{\left(\operatorname{deg} \tau_{k}+\operatorname{deg} \omega_{i}\right)\left(\operatorname{deg} \omega_{i}\right)} \int_{M \times M} \pi^{*}\left(\omega_{i} \wedge \tau_{k}\right) \rho^{*}\left(\omega_{i} \wedge \tau_{j}\right)
\end{aligned}
$$

Recall that the Poincare dual of a closed oriented submanifold $S$ is represented by the same form as the Thom class of a tubular neighborhood of $S$ (see (6.23)). Thus

$$
\begin{aligned}
\int_{\Delta} \eta_{\Delta} & =\int_{\Delta} \Phi\left(N_{\Delta}\right) \\
& \begin{array}{l}
\text { where } \Phi\left(N_{\Delta}\right) \text { is the Thom class of the normal } \\
\text { bundle } N_{\Delta} \text { regarded as a tubular neighborhood } \\
\text { of } \Delta \text { in } M \times M
\end{array} \\
& =\int_{\Delta} e\left(N_{\Delta}\right)
\end{aligned} \begin{aligned}
& \text { since the Thom class restricted to the zero } \\
& \text { section of the bundle is the Euler class }
\end{aligned}
$$

So the self-intersection number of the diagonal $\Delta$ in $M \times M$ is the Euler number of $M$. (By Poincare duality, $\int_{\Delta} \eta_{\Delta}=\int_{M \times M} \eta_{\Delta} \wedge \eta_{\Delta}$ is the selfintersection number of $\Delta$ in $M \times M$.)

Now the right-hand side of Lemma 11.22 evaluated on the diagonal $\Delta$ is

$$
\begin{aligned}
\int_{\Delta} \eta_{\Delta} & =\sum_{i}(-1)^{\operatorname{deg} \omega} \int_{\Delta} \pi^{*} \omega_{i} \wedge \rho^{*} \tau_{i} \\
& =\sum_{i}(-1)^{\operatorname{deg} \omega_{i}} \int_{M} i^{*} \pi^{*} \omega_{i} \wedge_{i} \rho^{*} \tau_{i} \\
& =\sum_{i}(-1)^{\operatorname{deg} \omega_{i}} \int_{M} \omega_{i} \wedge \tau_{i} \\
& =\sum_{i}(-1)^{\operatorname{deg} \omega_{i}} \\
& =\sum_{i}(-1)^{2} \operatorname{dim} H^{q}(M) \\
& =\chi(M) .
\end{aligned}
$$

Therefore,
Proposition 11.24. The Euler number of a compact oriented manifold $\int_{M} e\left(T_{M}\right)$
is equal to its Euler characteristic $\chi(M)=\Sigma(-1)^{q} \operatorname{dim} H^{q}$.
It is now a simple matter to derive the Hopf index theorem. Let $V$ be a vector field with isolated zeros on $M$. The index of $V$ at a zero $u$ is defined to be the local degree at $u$ of $V /\|V\|$ as a section of the unit tangent bundle
of $M$ relative to some Riemannian metric on $M$. By Theorem 11.16 the sum of the indices of $V$ is the Euler number of $M$. The equality of the Euler number and the Euler characteristic then yields the following.

Theorem 11.25 (Hopf Index Theorem). The sum of the indices of a vector field on a compact oriented manifold $M$ is the Euler characteristic of $M$.

Exercise 11.26 (Lefschetz fixed-point formula). Let $f: M \rightarrow M$ be a smooth map of a compact oriented manifold into itself. Denote by $H^{9}(f)$ the induced map on the cohomology $H^{q}(M)$. The Lefschetz number of $f$ is defined to be

$$
L(f)=\sum_{q}(-1)^{\natural} \operatorname{trace} H^{q}(f) .
$$

Let $\Gamma$ be the graph of $f$ in $M \times M$.
(a) Show that

$$
\int_{\Delta} \eta_{r}=L(f)
$$

(b) Show that if $f$ has no fixed points, then $L(f)$ is zero.
(c) At a fixed point $P$ of $f$ the derivative $(D f)_{P}$ is an endomorphism of the tangent space $T_{P} M$. We define the multiplicity, of the fixed point $P$ to be

$$
\sigma_{P}=\operatorname{sgn} \operatorname{det}\left((D f)_{P}-I\right)
$$

Show that if the graph $\Gamma$ is transversal to the diagonal $\Delta$ in $M \times M$, then

$$
L(f)=\sum_{P} \sigma_{P}
$$

where $P$ ranges over the fixed points of $f$. (For an explanation of the meaning of the multiplicity $\sigma_{P}$, see Guillemin and Pollack [1, p. 121].)

## §12 Thom Isomorphism and Poincaré Duality Revisited

In this section we study the Thom isomorphism and Poincaré duality from the tic-tac-toe point of view. The results obtained here are more general than those of Sections 5 and 6 in two ways:
(a) $M$ need not have a finite good cover, and
(b) the orientability assumption on the vector bundle $E$ has been dropped.

## The Thom Isomorphism

Let $\pi: E \rightarrow M$ be a rank $n$ vector bundle. $E$ is not assumed to be orientable. We are interested in the cohomology of $E$ with compact support in the vertical direction, $H_{c v}^{*}(E)=H^{*}\left\{\Omega_{c v}^{*}(E)\right\}$. Recall that
(a) $H_{c}^{*}\left(\mathbb{R}^{\prime \prime}\right)=\left\{\begin{array}{l}\mathbb{R} \text { in dimension } n \\ 0 \text { otherwise, }\end{array}\right.$
(b) (Poincaré lemma) $H_{c v}^{*}\left(M \times \mathbb{R}^{n}\right)=H^{*-n}(M)$.

Let $\mathfrak{U}$ be a good cover of the base manifold $M$. We augment the double complex $C^{*}\left(\pi^{-1} \mathfrak{U}, \Omega_{c v}^{*}\right)$ by adding a column consisting of the kernels of the first $\delta$ :

Using a partition of unity from the base, it can be shown that all the rows of this agumented double complex are exact. The proof is identical to that of the generalized Mayer-Vietoris sequence in (8.5) and will not be repeated here. From the exactness of the rows of the augmented complex, it follows as in (8.8) that the cohomology of the initial column is the total cohomology of the double complex, i.e.,

$$
H_{c \emptyset}^{*}(E) \simeq H_{D}\left\{C^{*}\left(\pi^{-1} \mathfrak{U}, \Omega_{c v}^{*}\right)\right\}
$$

On the other hand,

$$
\begin{aligned}
H p_{c} \cdot\left\{C^{*}\left(\pi^{-1} \mathfrak{U}, \Omega_{c v}^{*}\right)\right\} & =H_{c v}^{q}\left(\left\lfloor\pi^{-1} U_{a 0 \ldots a_{p}}\right)\right. \\
& =\prod H_{c v}^{q}\left(\pi^{-1} U_{a 0 \ldots a_{v}}\right) \\
& =C^{p}\left(\mathfrak{U}, \mathscr{x}_{c v}^{q}\right)
\end{aligned}
$$

where $\mathscr{H}_{c v}^{q}$ is the presheaf given by

$$
\mathscr{K}_{c v}^{q}(U)=H_{c v}^{C}\left(\pi^{-1} U\right) .
$$

By the Poincaré lemma for compactly supported cohomology, if $U$ is contractible, then

$$
\mathscr{X}_{c v}^{\mathrm{q}}(U)= \begin{cases}R & \text { if } q=n \\ 0 & \text { otherwise } .\end{cases}
$$

Therefore $H_{d}$ and also $H^{\cdot}{ }^{9} H_{d}=H\left\{\left\{C^{*}\left(\mathcal{H}, \mathscr{H}_{c v}^{q}\right)\right\}=H^{p}\left(\mathcal{H}, \mathscr{H}_{c q}^{q}\right)\right.$ have entries only in the nth row.

Proposition 12.1. Given any double complex $K$, if $H_{\delta} H_{d}(K)$ has entries only in one row, then $H_{d} H_{d}$ is isomorphic to $H_{D}$.

This proposition will be substantially generalized in Section 14, for it is simply an example of a degenerate spectral sequence. Its proof is a technical exercise which we defer to the end of this section. Combined with the preceding discussion, it gives

$$
H_{c v}^{*}(E)=H_{D}^{*}=\bigoplus_{p+q=*} H^{p}\left(\mathcal{U}, \mathscr{H}_{c v}^{q}\right)=H^{*-n}\left(\mathcal{U}, \mathscr{H}_{c v}^{n}\right) .
$$

This is the Thom isomorphism for a not necessarily orientable vector bundle.

Theorem 12.2 (Thom Isomorphism). For $\pi: E \rightarrow M$ any vector bundle of rank $n$ over $M$ and $\mathfrak{U}$ a good cquer of $M$,

$$
H_{c v}^{*}(E) \simeq H^{*-n}\left(\mathbb{U}, \mathscr{H}_{c v}^{n}\right),
$$

where $\mathscr{H}_{c v}^{n}$ is the presheaf $\mathscr{H}_{c v}^{n}(U)=H_{c v}^{n}\left(\pi^{-1} U\right)$.
We now deduce the orientable version of the Thom isomorphism from this. So suppose $\pi: E \rightarrow M$ is an orientable vector bundle of rank $n$ over $M$. This means there exist forms $\sigma_{a}$ on the sphere bundies $\left.S(E)\right|_{v_{a}}$ which restrict to a generator on each fiber and such that on overlaps $U_{\alpha} \cap U_{B}$ their cohomology classes agree: $\left[\sigma_{\alpha}\right]=\left[\sigma_{\beta}\right]$. Now choose a Riemannian metric on $E$ so that the "radius" $r$ is well-defined on each fiber and any function of the radius $r$ is a global function on $E$. Let $\rho(r)$ be the function shown in Figure 12.1. Then $(d \rho) \sigma_{a}$ is a form on $\left.E\right|_{\nu_{a}}$, where we regard $\sigma_{a}$ as a form on the complement of the zero section. Furthermore, $\left[(d \rho) \sigma_{a}\right] \in H_{c v}^{*}\left(\left.E\right|_{v_{a}}\right)$ restricts to a generator of the compactly supported cohomology of the fiber and $\left[(d \rho) \sigma_{\alpha}\right]=\left[(d \rho) \sigma_{\beta}\right]$ on $U_{A} \cap U_{B}$. Since the fiber has no cohomology in dimensions less than $n, \sigma^{0, n}=\left\{\sigma_{a}\right\}$ can be extended to a $D$-cocycle. This $D$-cocycle corresponds to a global closed form $\Phi$ on $E$, the Thom class of $E$, which restricts to a generator on each fiber. Now $\mathscr{H}_{c o}^{n}(U)$ is generated by $\left.\Phi\right|_{U}$ and for $V \subset U$ the restriction map from $\mathscr{X}_{c v}^{N}(U)$ to $\mathscr{X}_{c o}^{N}(V)$ sends $\left.\Phi\right|_{v}$

Figure 12.1
to $\left.\Phi\right|_{v}$. Hence, via the map which sends $\left.\Phi\right|_{u}$, for every open set $U$, to the generator 1 of the trivial presheaf $\mathbb{R}$, the presheaf $\mathscr{H}_{c v}^{n}$ is isomorphic to $\mathbb{R}$. The Thom isomorphism theorem then assumes the form

$$
\begin{equation*}
H_{c v}^{*}(E) \simeq H^{*-n}\left(\mathfrak{U}, \mathscr{H}_{c v}^{n}\right)=H^{*-n}(\mathcal{U}, \mathbb{R})=H^{*-n}(M), \tag{12.2.1}
\end{equation*}
$$

for an orientable rank $n$ vector bundle E. This agrees with Proposition 6.17. It holds in particular when $M$ is simply connected, since by (11.5), every vector bundle over a simply connected manifold is orientable.

From the explicit formula (11.11) for the global angular form on an oriented sphere bundle, we can derive a formula for the Thom class of an oriented vector bundle. Let $f: E^{0} \rightarrow S(E)$ be a deformation retraction of the complement of the zero section in $E$ onto the unit sphere bundle. If $\psi_{s}$ is the global angular form on $S(E)$, then $\psi=f^{*} \psi_{s} \in H^{n-1}\left(E^{0}\right)$ is the global angular form on $E^{0}$. It has the property that

$$
d \psi=-\pi^{*} e,
$$

where $e$ represents the Euler class of the bundle $E$.

Proposition 12.3. The cohomology class of

$$
\Phi=d(\rho(r) \cdot \psi) \in \Omega_{c v}^{n}(E)
$$

is the Thom class of the oriented vector bundle $E$.

Proof. Note that

$$
\begin{equation*}
\Phi=d \rho(r) \cdot \psi-\rho(r) \pi^{*} e \tag{12.3.1}
\end{equation*}
$$

For the same reasons as in the discussion following (6.40), $\Phi$ is a closed global form on $E$ with compact support in the vertical direction. Its restriction to the fiber at $p$ is $d \rho(r) \cdot i_{p}^{*} \psi$, where $t_{p}: E_{p} \rightarrow E$ is the inclusion and $i_{p}^{*} \psi$ gives a generator of $H^{n-1}\left(\mathbb{R}^{n}-\{0\}\right)=H^{n-1}\left(S^{n-1}\right)$. Since

$$
\int_{\mathbb{R}^{n}} d \rho(r) \cdot i_{p}^{*} \psi=\int_{\mathbb{R}^{1}} d \rho(r) \int_{s^{n-1}} i_{p}^{*} \psi=1
$$

by ( 6.18 ), $\Phi$ is the Thom class of $E$.

If $s$ is the zero section of $E$, then $s^{*} d \rho=0$ and $s^{*} \rho=-1$. By (12.3.1),

$$
s^{*} \Phi=-\left(s^{*} \rho\right) s^{*} \pi^{*} e=e .
$$

Thus,
Proposition 12.4. The pullback of the Thom class of an oriented rank $n$ vector bundle via the zero section to the base manifold is the Euler class.

Remark 12.4.1. From the formula for the Thom class (12.3), it is clear that by making the support of $\rho(r)$ sufficiently close to 0 , the Thom class $\Phi$ can be made to have support arbitrarily close to the zero section of the vector bundle.

Remark 12.4.2. In fact, in Proposition 12.4 any section will pull the Thom class back to the Euler class. Let $s$ be a section of the oriented vector bundle $E$ and $s^{*}: H_{c v}^{*}(E) \rightarrow H^{*}(M)$ the induced map in cohomology. Note that $s^{*}$ can be written as the composition of the natural maps $i: H_{c v}^{*}(E) \rightarrow H^{*}(E)$ and $\bar{s}^{*}: H^{*}(E) \rightarrow H^{*}(M)$. As a map from $M$ into $E$, the section $s$ is homotopic to the zero section $s_{0}$. By the homotopy axiom for de Rham cohomology (Cor. 4.1.2), $\vec{s}^{*}=\overrightarrow{s_{0}^{*}}$. Hence, $s^{*}=s_{0}^{*}$.

Using the description of the Euler class as the pullback of the Thom class, it is easy to prove the Whitney product formula.

Theorem 12.5 (Whitney Product Formula for the Euler Class). If $E$ and $F$ are two oriented vector bundles, then $e(E \oplus F)=e(E) e(F)$.

Proor. By Proposition 6.19, the Thom class of $E \oplus F$ is

$$
\Phi(E \oplus F)=\pi_{1}^{*} \Phi(E) \wedge \pi_{2}^{*} \Phi(F)
$$

where $\pi_{1}$ and $\pi_{2}$ are the projections of $E \oplus F$ onto $E$ zad $F$ respectively. Let $s$ be the zero section of $E \oplus F$. Then $\pi_{1} \circ s$ and $\dot{\pi}_{2} \circ s$ are the zero sections of $E$ and $F$. By Proposition 12.4,

$$
e(E \oplus F)=s^{*} \Phi(E \oplus F)=s^{\star} \pi_{1}^{*}(E) \wedge s^{*} \pi_{2}^{*} \Phi(F)=e(E) \varrho(F) .
$$

Exercise 12.6. Let $\pi: E \rightarrow M$ be an oriented vector bundle.
(a) Show that $\pi^{*} e=\Phi$ as cohomology classes in, $H^{*}(E)$, but not in $H_{c \infty}^{*}(E)$.
(b) Prove that $\Phi \wedge \Phi=\Phi \wedge \pi^{*} e$ in $H_{c}^{*}(E)$.

## Euler Class and the Zero Locus of a Section

Let $\pi: E \rightarrow M$ be a vector bundle and $S_{0}$ the image of the zero section in $E$. A section $s$ of $E$ is transversal if its image $S=s(M)$ intersects $S_{0}$ transversally. The purpo* of this section is to derive an interpretation of the Euler class of an oriented vector bundle as the Poincare dual of the zero locus of a transversel section. This is an analogue of Theorsm 11.17, which is more special in that $\operatorname{rank} E=\operatorname{dim} M$, but more general in that the section is not assumed to be transversal.

Proponition 12.7. Let $\pi: E \rightarrow M$ be any vector bundlefand $Z$ the zero locus of a transversal section. Then $Z$ is a submanifold of $M$ and tis normal buoudle ins $M$ is $\left.N_{\text {Z/M }} \simeq E\right|_{z}$.

Figure 12.2

Proof. Write $S=s(M)$ for the image of the section $s$ (see Figure 12.2). Because $S$ intersects $S_{0}$ transversally, $S \cap S_{0}$ is a submanifold of $S$ by the transversality theorem (Guillemin and Pollack [1, p. 28]). Under the diffeomorphism $s: M \rightarrow S, Z$ is mapped homeomorphically to $S \cap S_{0}$. So $Z$ can be made into a submanifold of $M$.

To compute the normal bundle of $Z$, we first note that because $E$ is locally trivial, its tangent bundle on $S_{0}$. has the following canonical decomposition

$$
\left.T_{E}\right|_{s_{0}}=\left.E\right|_{s_{0}} \oplus T_{S_{0}}
$$

By the transversality of $S \cap S_{0}$,

$$
T_{S}+T_{S_{0}}=T_{E}=E \oplus T_{S_{0}} \text { on } S \cap S_{0}
$$

Hence the projection $T_{S} \rightarrow E$ over $S \cap S_{0}$ is surjective with kernel $T_{S} \cap T_{S_{0}}$. Again by the transversality of $S \cap S_{0}, T_{s} \cap T_{s_{0}}=T_{S_{\cap}}$. So we have an exact sequence over $Z \simeq S \cap S_{0}$ :

$$
\left.\left.0 \rightarrow T_{z} \rightarrow T_{s}\right|_{z} \rightarrow E\right|_{z} \rightarrow 0
$$

Hence $\left.N_{Z / M} \simeq E\right|_{z}$.

In the proposition above, if $E$ and $M$ are both oriented, then the zero locus 2 of a transversal qection is naturally an oriented manifold, oriented in such a way that

$$
\left.E\right|_{Z} \oplus T_{2}=T_{M} l_{z}
$$

has the direct sum orientation.

Proposition 128. Let $\pi: E \rightarrow M$ be an oriented vector bundle over an oriented manifold $M$. Then the Euler class $e(E)$ is Poincaré dual to the zero locus of $\&$ transversal section.

Figure 12.3
Proof. We will identify $M$ with the image $S_{0}$ of the zero section. If $S$ is the image in $E$ of the transversal section $s: M \rightarrow E$, then the zero locus of $s$ is $Z=S \cap S_{0} . Z$ is a closed oriented submanifold of $M$ and by Proposition 12.7, its normal bundie in $M$ is $N_{Z / M}=\left.E\right|_{Z}$. Since $S$ is diffeomorphic to $M$, the normal bundle $N_{Z / S}$ of $Z$ in $S$ is also $\left.E\right|_{z}$. The normal bundies $N_{Z / M}$ and $\boldsymbol{N}_{Z_{\mid S}}$ will be identified with the tubular neighborhoods of $Z$ in $M$ and in $S$ respectively, as in Figure 12.3.

Choose the Thom class $\Phi$ of $E$ to have support so close to the zero section (Remark 12.4.1) that $\Phi$ restricted to the tubular neighborhood $\boldsymbol{N}_{\text {z/s }}$ in $S$ has compact support in the vertical direction. In Figure 12.3 the support of $\Phi$ is in the shaded region. We will now show that se $\Phi$ is the Thom class of the tubular neighborhood $N_{z / M}$ in $M$.

Let $E_{z}, S_{z}$, and $M_{z}$ be the fibers of $\left.E\right|_{z} \simeq N_{z / s} \simeq N_{z / M}$ respectively above the point $z$ in $Z$. Because $\Phi$ has compact support in $S_{z}, s^{*} \Phi$ has compact support in $\boldsymbol{M}_{\mathbf{z}}$. Furthermore,

$$
\begin{aligned}
& \int_{M_{z}} s^{*} \Phi=\int_{S_{z}} \Phi \quad \begin{array}{l}
\text { by the invariance of the integral under the } \\
\text { orientation-preserving diffeomorphism } s: M
\end{array} \\
& =\int_{E_{z}} \Phi \begin{array}{l}
\text { because } E_{z} \text { is homotopic to } S_{z} \text { modulo the region } \\
\text { in } E \text { where } \Phi \text { is zero }
\end{array} \\
& =1 \text { by the definition of the Thom class. }
\end{aligned}
$$

So $s^{*} \Phi$ is the Thom class of $N_{z / M}$. By Proposition 12.4, $s^{*} \Phi=e(E)$. Since by (6.24) the Thom class of $N_{Z / M}$ is Poincare dual to $Z$ in $M$, the Euler class $e(E)$ is Poincare dual to $Z$ in $M$.

## A Tic-Tac-Toe Lemma

In this section we will prove the technical lemma (Proposition 12.1) that if $H_{\delta} H_{d}$ of a double complex $K$ has entries in only one now, then $H_{d} H_{d}$ is isomorphic to the total cohomology $H_{D}(K)$. With this tic-tac-toc lemma we will re-examine the Mayer-Vietoris principle of Section 8.

Proof of proposition 12.1.

We first define a map $h: H_{d} H_{d} \rightarrow H_{D}$. Recall that $D=D^{\prime}+D^{\prime \prime}=\delta+\left(-1^{p}\right) d$. An element [ $\phi$ ] in $H_{\delta, i q}^{p, q} H_{d}$ may be represented by a $D$-cochain $\phi$ of degree ( $p, q$ ) such that

$$
\begin{aligned}
D^{\prime \prime} \phi & =0 \\
\delta \phi & =-D^{\prime \prime} \phi_{1} \text { for some } \phi_{1} .
\end{aligned}
$$

This is summarized by the diagram

$$
\begin{gathered}
\stackrel{\dot{0}}{D^{\prime \prime} \uparrow} \\
\\
\\
\\
\\
\\
\phi_{1}^{\delta} \\
\phi_{1}
\end{gathered}
$$

Since $H \delta^{+2 . q^{-1}} H_{d}=0, \delta \phi_{i}=-D^{\prime \prime} \phi_{2}$ for some $\phi_{2}$. Continuing in, this manner, we see that $\phi$ can be extended downward to a $D$-cocycle $\phi+$ $\phi_{1}+\cdots+\phi_{n}$. The map $h$ is defined by sending $[\phi]$ to $\left[\phi+\phi_{1}+\cdots+\phi_{n}\right]$.

Next we define the inverse map $g: H_{D} \rightarrow H_{d} H_{d}$. Let $\omega$ be a cocycie in $H_{D}$. As the image of $\omega$ we cannot simply take the component of $\omega$ in the nonzero row because $d$ of it may not be zero. Suppose $\omega=a+b+c+\cdots$ as shown.

We will move $\omega$ in its $D$-cohomology class so that it has nothing above the nonzero row. Since $d a=0$ and $\delta a=-D^{k} b$, a represents a cocycle in $H_{b} H_{d}$. But $H_{d} H_{d}=0$ at the position of $a_{3}$ so $a$ is 0 in $H_{8} H_{d}$; this implios that
$a=D^{\prime \prime} a_{1}$ for some $a_{1}$. Then $\omega-D a_{1}$ has no components in the first column. Thus we may assume $\omega=b+c+\cdots$. Again $b$ is 0 in $H_{\delta} H_{d}$, so that $b=\delta b_{1}+D^{\prime \prime} b_{2}$, where $D^{\prime \prime} b_{1}=0$. Then $\omega-D\left(b_{1}+b_{2}\right)=\left(c-\delta b_{1}\right)+\cdots$ starts at the nonzero row.

$$
\begin{aligned}
& 0 \\
& \uparrow \\
& \\
& \\
& b_{1} \rightarrow b \\
& \\
& \\
& \\
& \\
& \\
& b_{2} \rightarrow
\end{aligned}
$$

Thus given $[\omega] \in H_{D}$, we may pick $\omega$ to have no components above the nonzero row of $H_{d} H_{d}$, say $\omega=c+\cdots$. Then $d c=0$ and the map $g: H_{D} \rightarrow$ $H_{d} H_{d}$ is defined by sending [ $\omega$ ] to [c].

Provided they are well-defined, $h$ and $g$ are clearly inverse to each other.
Exercise 12.9. Show that $h$ and $g$ are well-defined.
Using Proposition 12.1 we can give more succinct proofs of the main results of Section 8. Let $\mathfrak{U}=\left\{U_{u}\right\}$ be an open cover of the manifold $M$ and $C^{p}\left(\mu, \Omega^{\prime}\right)=\Pi \Omega^{q}\left(U_{a_{0} \ldots, e_{p}}\right)$. By the exactness of the Mayer-Vietoris sequence, $H_{\delta}$ of the Cech-de Rham complex $C^{*}\left(\mathbb{U}, \Omega^{*}\right)$ is

so that $H_{d} H_{d}$ is

Since $H_{d} H_{d}$ has only one nonzero column, we conclude from Proposition 12.1 that

$$
H_{D}^{*}\left\{C^{*}\left(\mathcal{U}, \Omega^{*}\right)\right\} \simeq H_{D R}^{*}(M)
$$

for any cover $\mathfrak{u}$. This is the generalized Mayer-Vietoris principle (Proposition 8.8).

Now if $\mathfrak{U}$ is a good cover, $H_{d}$ of the Cech-de Rham complex is

and $H_{\mathbf{d}} H_{4}$ is

Again because $H_{\mathrm{d}} H_{\mathbf{d}}$ has only one nonzero row,

$$
\boldsymbol{H}_{D}^{*}\left\{C^{*}\left(\mathfrak{U}, \Omega^{*}\right)\right\} \simeq \boldsymbol{H}^{*}(\mathfrak{U}, \mathbf{R}) .
$$

This gives the isomorphism between de Rham cohomology and the Cech cohomology of a good cover with coefficients in the constant presheaf $\mathbf{R}$.

Exercise 12.10. Let $\mathbb{C P}^{4 \prime}$ have homogeneous coordinates $z_{0}, \ldots, z_{n}$. Define $U_{i}=\left\{z_{i} \neq 0\right\}$. Then $\mathcal{U}=\left\{U_{0}, \ldots, U_{n}\right\}$ is an open cover of $C^{p}$, although not a good cover. Compute $H^{*}\left(C^{*}\right)$ from the double complex $C^{*}\left(\mu_{1}, \Omega^{*}\right)$. Find elements in $C^{*}\left(\mathbb{U}, \Omega^{*}\right)$ which represent the generators of $H^{*}\left(\mathrm{CP}^{\prime \prime}\right)$.

Exercise 12.11. Apply the Thom isomorphism (12.2) to compute the cohomology with compact support of the open Möbius strip (cf. Exercise 4.8).

## Poincaré Duality

In the same spirit as above, we now give a version of Poincare duality, in terms of the Cech-de Rham complex, for a not necessarily orientable manifold. Let $M$ be a manifold of dimension $n$ and $\mathcal{U}=\left\{U_{a}\right\}$ any open cover of $M$. Define the coboundary operator

$$
\delta: \bigoplus \Omega_{c}^{*}\left(U_{\alpha_{0} \ldots \alpha_{p}}\right) \rightarrow \bigoplus \Omega_{c}^{*}\left(U_{\alpha_{0} \ldots \alpha_{p-t}}\right)
$$

by the formula

$$
(\delta \omega)_{a_{0} \ldots a_{p-1}}=\sum_{\varepsilon} \omega_{a a_{0} \ldots a_{p-1}}
$$

where on the right-hand side we mean the extension by zero of $\omega_{\text {meo....ap-1 }}$ to a form on $U_{a 0 \ldots a_{p}, i}$. To ensure that each component of $\delta \omega$ has compact support, the groups here are direct sums rather than direct products, so that $\omega \in \bigoplus \Omega\left(U_{a 0} \ldots a_{p}\right)$ by definition has only a finite number of inonzero components.

Proposition 12.12 (Generalized Mayer-Vietoris Sequence for Compact Supports). The sequence

$$
\begin{aligned}
& 0 \longleftarrow \Omega_{c}^{*}(M) \stackrel{s u m}{\leftrightarrows} \oplus \Omega_{c}^{*}\left(U_{x 0}\right) \leftarrow \oplus \Omega_{c}^{*}\left(U_{a_{0} x_{1}}\right) \\
& \leftarrow \cdots \leftarrow \oplus \Omega_{c}^{*}\left(U_{\infty_{0} \ldots c_{0}}\right) \leftarrow \cdots
\end{aligned}
$$

is exact.
Proof. We first show $\delta^{2}=0$. Let $\omega$ be in $\bigoplus \Omega_{r}^{*}\left(U_{\alpha_{\hat{c}} \ldots \mu_{p}}\right)$. Then

$$
\begin{aligned}
\left(\delta^{2} \omega\right)_{x_{0} \ldots x_{p-2}} & =\sum_{a}(\delta \omega)_{\alpha a 0 \ldots \alpha_{p-2}}=\sum_{a} \sum_{\beta} \omega_{\beta \alpha_{0} \ldots \alpha_{p-2}} \\
& =0, \text { since } \omega_{a \beta \ldots}=-\omega_{\beta \alpha \ldots} .
\end{aligned}
$$

Now suppose $\delta \omega=0$. We will show that $\omega$ is a $\delta$-coboundary. Let $\left\{\rho_{\mathrm{a}}\right\}$ be a partition of unity subordinate to the cover $U$. Define

$$
\tau_{\alpha_{0} \ldots a_{p+1}}=\sum_{i=0}^{p+1}(-1)^{i} \rho_{\alpha_{i}} \omega_{\alpha_{0} \ldots a_{1} \ldots \alpha_{p+1}} .
$$

Note that $\tau_{\alpha_{0} \ldots a_{p+1}}$ has compact support. Then

$$
\begin{aligned}
& (\delta \tau)_{a_{0} \ldots, c_{p}}=\sum_{a} \tau_{\text {aapo } \ldots a_{r}} \quad . \quad .! \\
& =\sum_{a}\left(\rho_{a} \omega_{a 0 \ldots}+\sum_{i}(-1)^{i+1} \rho_{a j} \omega_{a m o} \ldots a_{1} \ldots a_{p}\right) \\
& =\omega_{a_{0} \ldots a_{p}}+\sum_{i}(-1)^{i+1} \rho_{a d}(\delta \omega)_{a_{0} \ldots a_{i} \ldots \varepsilon} \\
& =\omega_{a 0} \ldots c_{p} .
\end{aligned}
$$

Exercise 12．12．1．Show that the definition of $\tau$ in the proof above provides a homotopy operator for the compact Mayer－Vietoris sequence（12．12）．More precisely，if $\omega$ is in $\oplus \Omega_{c}^{*}\left(U_{\text {eo ．．．．⿰㇒⿻土一⿰丿⿺⿻⿻一㇂㇒丶一灬}}\right)$ and

$$
(K \omega)_{a_{0} \ldots \alpha_{p+1}}=\sum_{i=1}^{p+1}(-1)^{l} \rho_{a<} \omega_{a_{0} \ldots a_{1} \ldots a_{p}+1}
$$

then

$$
\delta K+K \delta=1
$$

Consider the double complex $C^{p}\left(\mathcal{U}, \Omega_{c}^{q}\right)$ ：

In this double complex the $\delta$－operator goes in the wrong direction，so we define a new complex

$$
K^{-p, q}=C^{p}\left(u, \Omega_{c}^{q}\right)
$$

By the exactness of the rows，$H_{d}(K)$ is

Since $H_{d} H_{d}$ has only one nonzero column. it follows from Proposition 12.1 that

$$
\begin{equation*}
H_{D}(K)=H_{s} H_{\partial}(K)=H_{c}(M) \tag{12.13}
\end{equation*}
$$

On the other hand, if 21 is a good cover, then $H_{d}(K)$ is

$$
H_{\Delta}{ }^{p \cdot \psi}(K)=C^{p}\left(\mu, \mathscr{K}_{c}^{\prime q}\right)
$$

where $\mathscr{H}^{q}$ : is the covantant functor which associates to every open set $U$ the compact cohomology $H_{s}^{4}\left(U^{\prime}\right)$ and to every inclusion $i$, the extension by zero, $i_{*}$; moreover,

$$
H_{d}{ }^{p, q}(K)=0 \quad \text { for } q \neq n .
$$

Again by Proposition 12.1,

$$
\begin{equation*}
H_{D}^{*}(K)=H_{\delta}^{*-n, n} H_{d}=H_{n-1}\left(\mathcal{U}, \mathscr{H}_{c}^{n}\right) \tag{12.14}
\end{equation*}
$$

Here $H_{n \cdot *}\left(\mathcal{I}, \mathscr{K}_{c}^{n}\right)$ is the ( $\left.n-*\right)$-th Čech homology of the cover $\mathbb{U}$ with cotficients in the covariant functor $\mathscr{H}_{6}^{n}$ (cf. Remark 10.3). Comparing (12.13) and (12.14) gives

Theorem 12.15 (Poincare Duality). Let $M$ be a manifold of dimension $n$ and 4 uny good cover of $M$. Here $M$ is not assumed to be orientable. Then

$$
H_{c}^{*}(M) \simeq H_{n \ldots}\left(\mathbb{U}, \mathscr{H}_{c}^{n}\right)
$$

where $\mathscr{H}_{c}^{n}$ is the covariant functor $\mathscr{H}_{c}^{n}(U)=H_{c}^{n}(U)$.
Exercise 12.16. By applying Poincare duality (12.15), compute the compact cohomology of the open Möbius strip (cf. Exercise 4.8).

## s13 Monodromy

## When Is a Locally Constant Presheaf Constant?

In the preceding section we saw that the compact vertical cohomology $H_{c t}^{*}(E)$ of a vector bundle $E$ may be computed as the cohomology of the base with coefficients in a locally constant presheaf. When this locally constant presheaf is the constant presheaf $\mathcal{R}^{n}, H_{c v}^{*}(E)$ is expressible in terms of
the de Rham cohomology of the base manifold (Proposition 10.6). In this case the problem of computing $H_{c v}^{*}(E)$ is greatly simplified. It is therefore important to determine the conditions under which a locally constant presheaf is constant.

First we need to review some basic definitions from the theory of simplicial complexes (see, for instance, Croom [1]). Recall that if an $n$-simplex in an Euclidean space has vertices $v_{0}, \ldots, v_{n}$, then its barycenter is the point $\left(v_{0}+\cdots+v_{n}\right) /(n+1)$. For example, the barycenter of an edge is its midpoint and the barycenter of a triangle (a 2 -simplex) is its center. The first barycentric subdivision of a simplex $\sigma$ is the simplicial complex having all the barycenters of $\sigma$ as vertices. By applying the barycentric subdivision to each simplex of a simplical complex $K$, we obtain a new simplicial complex $K^{\prime}$, called the first barycentric subdivision of $K$. The support of $K$, denoted $|K|$, is the underlying topological space of $K$, and the $k$-skeleton of $K$ is the subcomplex consisting of all the simplices of dimension less than or equal to $k$. The complex $K$ and its barycentric subdivision $K^{\prime}$ have the same support. The star_of_ a vertex simplices in $K$ having $v$ as a vertex.

Next we introduce the notion of a presheaf on an open cover. Let $X$ be a topological space and $\mathfrak{U}=\left\{U_{a}\right\}$ an open cover of $X$. The presheaf $\mathscr{F}$ on $\mathfrak{U}$ is defined to be a functor $\mathscr{F}$ on the subcategory of Open $(X)$ consisting of all finite intersections $U_{\alpha_{0} \ldots \alpha_{\rho}}$ of open sets in $\mathfrak{U}$. Equivalently, if $N(\mathfrak{U})$ is the nerve of $\mathfrak{U}$, the presheaf $\mathscr{F}$ on $\mathfrak{U}$ is the assignment of an appropriate group to the barycenter of each simplex in $N(\mathfrak{l})$; for example, the group attached to the barycenter of the 2 -simplex representing $U \cap V \cap W$ is $\mathscr{F}(U \cap V \cap W)$. Each inclusion, say $U \cap V \rightarrow U$, becomes an arrow in the picture, $\mathscr{F}(U) \rightarrow \mathscr{F}(U \cap V)$, and the transitivity of the arrows says that Figure 13.1 is a commutative diagram.

Figure 13.1

Two presheaves $\mathscr{F}$ and $\mathscr{G}$ are isomorphic relative to an open cover $\mathbb{U}=$ $\left\{U_{a}\right\}$ if for each $W=U_{a_{0} \ldots \alpha_{p}}$ there is an isomorphism

$$
h_{W}: \mathscr{F}(W) \rightarrow \mathscr{G}(W)
$$

compatible with all arrows. In other words, there is a natural equivalence of functors $\mathscr{F} \rightarrow \mathscr{G}$ where $\mathscr{F}$ and $\mathscr{G}$ are regarded as functors on the subcategory of $\operatorname{Open}(X)$ consisting of all finite intersections $U_{\alpha_{0} \ldots \alpha_{p}}$ of open sets in $\mathfrak{U}$. The trivial presheaf and the constant presheaf on an open cover $\mathfrak{U}$ are defined as in Section 10. However, the definition of a locally constant presheaf on $u$ requires some care, since the notion of "local" does not make sense on a cover. We say that a presheaf $\mathscr{F}$ is locally constant on $\mathcal{U}$ if all the groups $\mathscr{F}\left(U_{\alpha_{0} \ldots a_{p}}\right)$ are isomorphic and all the arrows are isomorphisms. Note that a locally constant presheaf on a space $X$ is locally constant on some open cover, and conversely.

Of course, if two presheaves $\mathscr{F}$ and $\mathscr{G}$ are isomorphic on an open cover. $\mathfrak{U}$, then the cohomology groups $H^{*}(\mathfrak{U}, \mathscr{F})$ and $H^{*}(\mathfrak{U}, \mathscr{G})$ are isomorphic.

Figure 13.2

Example 13.1 (A locally constant presheaf on $\mathfrak{U}$ which is not constant). Let $\mathfrak{U}=\left\{U_{0}, U_{1}, U_{2}\right\}$ be a good cover of the circle $S^{1}$ (see Figure 13.2). Define a presheaf $\mathscr{F}$ by

$$
\begin{aligned}
\mathscr{F}(U) & =\mathbb{Z} \text { for all open sets } U \\
\rho_{01}^{0} & =\rho_{(11}^{1}=\rho_{12}^{1}=\rho_{12}^{2}=1 \\
\rho_{02}^{2} & =-1, \rho_{02}^{0}=1
\end{aligned}
$$

$\mathscr{F}$ is locally constant but not constant on $\mathcal{U}$ because $\rho_{02}^{2}$ is not the identity.
Let $\mathscr{F}$ be a locally constant presheaf with group $G$ on an open cover $\mathfrak{U}=\left\{U_{\alpha}\right\}$. Fix isomorphisms

$$
\phi_{a}: \mathscr{F}\left(U_{a}\right) \leadsto G
$$

If $U_{a}$ and $U_{\beta}$ intersect, then from the diagram

we obtain an automorphism of $G$, namely $\phi_{\beta}\left(\rho_{\alpha \beta}^{\beta}\right)^{-1} \rho_{\alpha \beta}^{\alpha} \phi_{\alpha}^{-1}$. Write $\rho_{\beta}^{\alpha}$ : $\mathscr{F}\left(U_{z}\right) \rightarrow \mathscr{F}\left(U_{\beta}\right)$ for the isomorphism $\left(\rho_{a \beta}^{\beta}\right)^{-1} \circ \rho_{a \beta}^{a}$. Choose some vertex $U_{0}$ as the base point of the nerve $N(\mathbb{U})$. For $U_{0} U_{1} \ldots U_{r} U_{0}$ a loop based at $U_{0}$ we get an automorphism of $G$ by following along the edges

This gives a map from \{loops at $\left.U_{0}\right\}$ to Aut $G$. We claim that if a loop bounds a 2 -chain, then the associated automorphism of $G$ is the identity. Consider the example of the 2 -simplex as shown in Figure 13.3.

Figure 13.3

(a)

$$
\rho_{0}^{2}\left(\rho_{12}^{2}\right)^{-1}\left(\rho_{012}^{12}\right)^{-1} \rho_{012}^{0} \rho_{01}^{0}
$$

(c)

$\left(\rho_{02}^{0}\right)^{-1}\left(\rho_{012}^{02}\right)^{-1} \rho_{012}^{01} \rho_{01}^{0}$
(e)

(b)

$\rho_{0}^{2}\left(\rho_{012}^{2}\right)^{-1} \rho_{012}^{01} \rho_{02}^{0}$
(d)

$\left(\rho_{012}^{0}\right)^{-1} \rho_{012}^{01} \rho_{01}^{0}=1$
(f)

Figure 13.4
The associated automorphism of the loop $U_{0} U_{1} U_{2}$ is $\phi_{0}\left(\rho_{0}^{2} \rho_{2}^{1} \rho_{1}^{0}\right) \phi_{0}^{-1}$ so it is a matter of showing that $\rho_{0}^{2} \rho_{2}^{1} \rho_{1}^{0}$ is the identity. This is clear from the sequence of pictures in Figure 13.4, where we use heavy solid lines to indicate maps which, by the commutativity of the arrows, are all equal to $\rho_{0}^{2} \rho_{2}^{1} \rho_{1}^{0}$.

More generally; the same procedure shows that the map $\rho_{0}^{\alpha} \ldots \rho_{\beta}^{0}$ around any bounding loop is the identity. Hence there is a homomorphism

$$
\rho: \pi_{1}(N(\mathcal{U}))=\frac{\{\text { loops }\}}{\{\text { bounding loops }\}} \rightarrow \text { Aut } G
$$

called the monodromy representation of the presheaf $\mathscr{F}$. Here $\pi_{1}(N(\mathfrak{U}))$ denotes the edge path group of the nerve $N(\mathfrak{U})$ as a simplicial complex.

Theorem 13.2. Let $\mathfrak{U}$ be an open cover on a connected topological space $X$ and $N(\mathfrak{U})$ its nerve. If $\pi_{1}(N(\mathfrak{U}))=0$, then every locally constant presheaf on $\mathfrak{U}$ is constant.

Proof. Suppose $\pi_{1}(N(\mu))=0$, i.e., every loop bounds some 2 -chain. For each open set $U_{a}$, choose a path from $U_{0}$ to $U_{\alpha}$, say $U_{0} U_{\alpha_{1}} \ldots U_{a_{1}} U_{\alpha}$, and define $\psi_{\alpha}=\phi_{0}\left(\rho_{\alpha}^{\alpha_{\alpha}} \ldots \rho_{\alpha_{2}}^{\alpha_{1}} \rho_{a_{1}}^{0}\right)^{-1}: \mathscr{F}\left(U_{\alpha}\right) \rightarrow G$.

$\psi_{\alpha}$ is well-defined independent of the chosen path, because as we have seen, around a bounding loop the map $\rho_{o}^{\alpha} \ldots \rho_{\beta}^{0}$ is the identity.

Now carry out the barycentric subdivision of the nerve $N(\mathfrak{U})$ to get a new simplicial complex $K$ so that every open set $U_{a_{0} \ldots, \alpha_{0}}$ corresponds to a vertex of $K$. Clearly $\pi_{1}(N(\mathbb{U}))=\pi_{1}(K)$. By the same procedure as in the preceding paragraph we can define isomorphisms

$$
\psi_{\alpha_{0} \ldots \alpha_{p}}: \mathscr{F}\left(U_{\alpha_{0} \ldots \alpha_{p}}\right) \rightarrow G
$$

for all nonempty $U_{x_{0} \ldots \alpha_{p}}$. The maps $\psi_{\alpha_{0} \ldots \alpha_{p}}$ give an isomorphism of the presheaf $\mathscr{F}$ to the constant presheaf $G$ on the cover $\mathcal{U}$.

Remark 13.2.1. If the group $G$ of a locally constant presheaf has no automorphisms except the identity, then there is no monodromy. In particular, every locally constant presheaf with group $\mathbb{Z}_{2}$ is constant.

Remark 13.3. Recall that a simplicial map between two simplicial complexes $K$ and $L$ is a map $f$ from the vertices of $K$ to the vertices of $L$ such that if $v_{0}, \ldots, v_{n}$ span a simplex in $K$, then $f\left(v_{0}\right), \ldots, f\left(v_{n}\right)$ span a simplex in L. A simplicial map $f$ from $K$ to $L$ induces a map $f:|K| \rightarrow|L|$ by linearity:

$$
f\left(\sum \lambda_{i} v_{i}\right)=\sum \lambda_{i} f_{i}\left(v_{i}\right) .
$$

By abuse of language we refer to either of these maps as a simplicial map.

For the proof of the next theorem we assemble here some standard facts from the theory of simplicial complexes.
(a) The edge path group of a simplicial complex is the same as that of its 2-skeleton (Seifert and Threlfall [1, $\$ 44$, p. 167]).
(b) The edge path group of a simplicial complex is the same as the topological fundamental group of its support (Seifert and Threlfall [1, §44, p. 165]).
(c) (The Simplicial Approximation Theorem). Let $K$ and $L$ be two simplicial complexes. Then every map $f:|K| \rightarrow|L|$ is homotopic to a simplicial map $g:\left|K^{(k)}\right| \rightarrow|L|$ for some integer $k$, where $K^{(k)}$ is the $k$-th barycentric subdivision of $K$ (Croom [1, p. 49]).

Because of (b) we also refer to the edge path group of a simplicial complex as its fundamental group.

None of these facts are difficult to prove. They all depend on the following very intuitive principle from obstruction theory.

The Extension Principle. A map from the union of all the faces of a cube into a contractible space can be extended to the entire cube.

Aside. With a little homotopy theory the extension principle can be refined as follows. Let $X$ be a topological space and $I^{k}$ the unit $k$-dimensional cube. If $\pi_{q}(X)=0$ for all $q \leq k-1$, then any maps from the boundary of $I^{k}$ into $X$ can be extended to the entire cube $I^{k}$.

In section 5 we defined a good cover on a manifold to be an open cover $\left\{U_{a}\right\}$ for which all finite intersections $U_{\alpha_{0}} \cap \cdots \cap U_{\varepsilon}$, are diffoomorphic to a Euclidean space. By a good cover on a topological space we shall mean an open cover for which all finite intersections are contractible.

Remark. Thus, on a manifold there are two notions of a good cover. We do not know if they are equivalent in all dimensions. It appears to be a difficult question whether every contractible manifold of dimension $n$ is difficomorphic to $\mathbb{R}^{n}$, for an affirmative answer would imply the generalized Poincare conjecture (which states that a compact manifold of dimension $n$ having the homotopy type of the $n$-sphere $S^{n}$ is humeomorphic to $S^{n \prime}$ ). The generalized Poincaré conjecture is still open for $n=3$ and $n=4$, the case where $n>4$ having been proved by Smale [1]. For a good cover on a manifold, we will always stick to the more restrictive hypothesis that the finite intersections are diffeomorphic to $\mathbb{R}^{n}$. This is because in order to prove Poincaré duality, whether by the Mayer-Vietoris argument of Section 5 or by the tic-tac-toe game of Section 12, we need the compact Poincaré lemma (Corollary 4.7), which is not always true for an open set with merely the homotopy type of $\mathbb{R}^{n}$.

Theorem 13.4. Suppose the topological space $X$ has a good cover U. Then the fundamental group of $X$ is isomorphic to the fundumental group $\pi_{1}(N(\mathfrak{U}))$ of the nerve of the good cover.

Proof. Write $N_{2}(\mathfrak{U})$ for the 2 -skeleton of the nerve $N(\mathcal{U})$. Let $U_{i}, U_{i j}$, and $U_{i j k}$ be the barycenters of the vertices, edges, and faces of $N_{2}(\mathfrak{U})$ and let $N_{2}^{\prime}(\mathcal{U})$ be its barycentric subdivision. As the first step in the proof of the theorem we will define a map $f$ from $\left|N_{2}^{\prime}(l)\right|$ to $X$. We will then show that this map induces an isomorphism of fundamental groups.

To this end choose a point $p_{i}$ in eaci open set $U$. in $\mathcal{U}$, a point $p_{i j}$ in each nonempty pairwise intersection $U_{i j}$, and a point $p_{i j k}$ in each nonempty triple intersection $U_{i j k}$. Also, fix a contraction $c_{i}$ of $U_{i}$ to $p_{i}$ and a contraction $c_{i j}$ of $U_{i j}$ to $p_{i j}$. These contractions exist because $\mathcal{H}$ is a good cover. By decree the map $f$ sends $U_{i}, U_{i j}$, and $U_{i j k}$ to $p_{i}, p_{i j}$, and $p_{i j k}$ respectively.

Figure 13.5
Next we define $f$ on the edges of $\left|N_{2}^{\prime}(\mu)\right|$. The contraction $c_{i}$ takes $p_{i j}$ to $p_{i}$ and gives a well-defined path between $p_{i}$ and $p_{i j}$. Similarly, the contraction $c_{j}$ gives a well-defined path between $p_{j}$ and $p_{i j}$ (see Figure 13.5). Furthermore, for each point $p_{i j k}$ the six contractions $c_{i}, c_{j}, c_{k}, c_{i j}, c_{i k}$, and $c_{j k}$ produce six paths in $X$ joining $p_{i j k}$ to $p_{i}, p_{j}, p_{k}, p_{i j}, p_{i k}$, and $p_{j k}$ respectively (see Figure 13.6).

Figure 13.6

The map $f$ shall send the edges of $\left|N_{2}^{\prime}(\mathcal{U})\right|$ to the paths just defined; for example, the edge $U_{i} U_{i j k}$ is sent to the path joining $p_{i}$ and $p_{i j k}$.

Finally we define $f$ on the faces of $\left|N_{2}^{\prime}(\hat{l})\right|$. Since each "triangle" $p_{i} p_{i j} p_{i j k}$ lies entirely inside the open set $U_{i}$ (such a triangle may be degenerate; i.e., it may only be a point or a segment), the triangle may be "filled in" in a well-defined manner: to fill in the triangle $p_{i} p_{i j} p_{i j k}$, use the contraction $c_{i}$ to contract the edge $p_{i j} p_{i j k}$ to $p_{i}$ (see Figure 13.6). This "filled-in" triangle will be the image of the triangle $U_{i} U_{j} U_{i j k}$ under $f$. In summary, with the choice of the points $p_{i}, p_{i j}, p_{i j k}$ and the contractions $c_{i}, c_{i j}$ fixed, we have defined a $\operatorname{map} f:\left|N_{2}^{\prime}(\mathfrak{U})\right| \rightarrow X$. We will now show that the induced map of fundamental groups, $f_{*}: \pi_{1}\left(\left|N_{2}^{\prime}(\mathfrak{U})\right|\right) \rightarrow \pi_{1}(X)$ is an isomorphism.

Step 1 (Surjectivity of $f_{*}$ ). Take $p_{0}$ in $U_{0}$ to be the base point of $X$. Let $\gamma: S^{1} \rightarrow X$ be a loop in $X$ based at $p_{0}$. We would like to deform $\gamma$ to a map of the form $\hat{f}_{*}(\vec{\gamma})$, where $\bar{\gamma}: S^{2} \rightarrow\left|\hat{N}_{2}(\mathfrak{U})\right|$ is a loop in $\left|N_{2}(\mathbb{U})\right|$ based at $U_{0}$.

Regard $S^{1}$ as the unit interval $I$ with its endpoints identified. To define $\bar{\gamma}$, we first subdivide the unit interval into equal pieces, so that it becomes a simplicial complex $K$ with vertices $q_{0}, \ldots, q_{m}$ (Figure 13.7).

Figure 13.7.
By making the pieces sufficiently small, we can ensure that the star of $q_{i}$ in the barycentric subdivision $K^{\prime}$ of $K$ is mapped entirely into an open set $U_{a(t)}$ :

$$
\gamma\left(s t\left(q_{i}\right)\right) \subset U_{a(i)} .
$$

To simplify the notation, write $j$ instead of $i+1$, so that $q_{1} q_{j}$ is a 1 simplex in $K$. Let $q_{i j}$ be the midpoint of $q_{i} q_{j}$. Define $\bar{\gamma}: S^{5} \rightarrow\left|N_{2}(\mu)\right|$ by sending the segment $q_{i} q_{j}$ to the segment $U_{\text {a(i) }} U_{a(\lambda)}$; it follows that $\bar{\gamma}\left(q_{i}\right)=$ $U_{a(i)}$ and $f_{*}(\vec{\gamma})\left(q_{i}\right)=p_{a(i)}$.

Next define a map $F$ on the sides of the square $I^{2}$ by (see Figure 13.8)

$$
\begin{aligned}
& \left.F\right|_{\text {botiom ide }}=F(x, 0)=\gamma(x),
\end{aligned}
$$

and

$$
\left.F\right|_{\text {wertical sidee }}=F(0, t)=F(1, t)=p_{0} .
$$

The problem now is to extend $F: \partial I^{\mathbf{2}} \rightarrow X$ to the entire square. Subdivide the square by joining with vertical segments the vertices $\left(q_{i}, 0\right),\left(q_{u}, 0\right)$ on the bottom edge to the corresponding vertices on the top edge. Since $F\left(q_{i}, 0\right)=\gamma\left(q_{i}\right)$ and $F\left(q_{i}, 1\right)=f_{*} \bar{\gamma}\left(q_{i}\right)=p_{a(i)}$, they both lie in $U_{a(i)}$. Since $U_{a(i)}$ is contractible, by the extension principle $F$ can be extended to the

Figure 13.8
vertical segment $\left\{q_{i}\right\} \times I$. Similarly, $F$ can be extended to the vertical segment $\left\{q_{i j}\right\} \times I$. Thus in Figure 13.8, $F$ is defined on the boundary of each rectangle and maps that boundary entirely into a contractible open set $U_{a}$. By the extension principle again, $F$ can be extended over each rectangle. In this way $F$ is extended to the entire square $I^{2}$.

STEP 2 (Injectivity of $f_{*}$ ). Suppose $\gamma: I \rightarrow\left|N_{2}(\mathfrak{U})\right|$ is a loop such that $f_{*}(\gamma)$ is null-homotopic in $X$. This means there is a map $H$ from the square $I^{2}$ to $X$ as in Figure 13.9.

Figure 13.9
By the simplicial approximation theorem we may assume that $\gamma$ is a simplicial map from some subdivision $L$ of the top edge of the square to $\left|N_{2}(\mathfrak{l})\right|$. Now subdivide the square $I^{2}$ repeatedly to get a triangulation $K$ with the property that if $q_{i}$ is a vertex of $K$ and $\operatorname{st}\left(q_{i}\right)$ is the star of $q_{i}$ in the barycentric subdivision $K^{\prime}$, then

$$
H\left(s t\left(q_{i}\right)\right) \subset U_{a(i)}
$$

for some open set $U_{a(i)}$ in $\mathbb{U}$. In the process of the subdivision new vertices are introduced on the top edge only by repeated bisection of the edge; furthermore, the function $\alpha$ on the vertices of the top edge may be chosen as follows. Consider for example the 1 -simplex $q_{1} q_{2}$. If $q_{k}$ is a new vertex to the left of the midpoint $q_{12}$, choose $q(k)=\alpha(1)$; otherwise, choose $q(k)=\alpha(2)$.

## Define

$$
A: I^{2}=\left|K^{\prime}\right| \rightarrow\left|N_{2}^{\prime}(\mu)\right|
$$

to be the simplicial map with

$$
H\left(q_{1}\right)=U_{\alpha(0)} .
$$

The restriction $\beta$ of $\bar{H}$ to the top edge of the square agrees with $\gamma$ on the vertices of $L$. Furthermore, by construction $\beta$ is homotopic to $\gamma$ in $\left|N_{2}(2)\right|$, and $\bar{H}$ is a null-homotopy for $\beta$. Therefore, $f_{*}: \pi_{1}\left(\left|N_{2}(2)\right|\right) \rightarrow \pi_{1}(X)$ is injective. Since the nerve $N(\mathfrak{l})$ and its 2 -skeleton $N_{2}(\mathfrak{l})$ have the same fundamental group (Remark 13.3 (a)), the theorem is proved.

## Examples of Monodromy

Example 13.5. Let $S^{1}$ be the unit circle in the complex plane with good cover $\mathfrak{U}=\left\{U_{0}, U_{1}, U_{2}\right\}$ as in Figure 13.10. The map $\pi: z \rightarrow z^{2}$ defines a fiber bundle $\pi: S^{1} \rightarrow S^{1}$ each of whose fibers consists of two distinct points. Let $F=\{A, B\}$ be the fiber above the point 1 . The cohomology $H^{*}(F)$ consists of all functions on $\{A, B\}$, i.e., $H^{*}(F)=\left\{(a, b) \in \mathbf{R}^{2}\right\}$.

Fix an isomorphism $H^{*}\left(\pi^{-1} U_{0}\right) \simeq H^{*}(F)$. We have the diagram

If we start with a generator, say $(1,0)$, of $H^{*}(F)$ and follow it around the diagram, we do not end up with the same generator; in fact, we get $(0,1)$. In general $(a, b)$ goes to $(b, a)$. Therefore the presheaf $\mathscr{H}^{*}(U)=H^{*}\left(\pi^{-1} U\right)$ is not a constant presheaf.

Figure 13.10
Exercise 13.6. Since $H_{d}$ of the double complex $C^{*}\left(\pi^{-1} \mathfrak{U}, \Omega^{*}\right)$ in Example 13.5 has only one nonzero row, we see by the generalized Mayer-Vietoris principle and Proposition 12.1 that

$$
H^{*}\left(S^{1}\right)=H_{D}^{*}\left\{C^{*}\left(\pi^{-1} \mathfrak{U}, \Omega^{*}\right)\right\}=H_{\delta} H_{d}=H^{*}\left(\mathfrak{U}, \mathscr{H}^{0}\right) .
$$

Compute the Čech cohomology $H\left(\mathscr{U}, \mathscr{H}^{0}\right)$ directly.
Example 13.7. The universal covering $\pi: \mathbb{R}^{1} \rightarrow S^{1}$ given by $\pi(x)=e^{2 \pi i x}$ is a fiber bundle with fiber a countable set of points. The action of the loop downstairs on the homology $H_{0}$ (fiber) is translation by $1: x \mapsto x+1$. In cohomology a loop downstairs sends the function on the fiber with support at $x$ to the function with support at $x+1$. (See Figure 13.11.)

Figure 13.11
Exercise 13.8. As in Example 13.5, with $\mathfrak{U}$ being the usual good cover of $S^{1}$,

$$
H^{*}\left(\mathbb{R}^{1}\right)=H_{D}^{*}\left\{C^{*}\left(\pi^{-1} \mathfrak{U}, \Omega^{*}\right)\right\}=H_{\delta} H_{d}=H^{*}\left(\mathfrak{U}, \mathscr{H}^{0}\right) .
$$

Compute $H^{*}\left(\mathfrak{U}, \mathscr{H}^{0}\right)$ directly.

Example 13.9. In the previous two examples, the fundamental group of the base acts on $H_{0}$ of the fiber. We now give an example in which it acts on $\mathrm{H}_{2}$.

The wedge $S^{m} \vee S^{n}$ of two spheres $S^{m}$ and $S^{n}$ is the union of $S^{m}$ and $S^{n}$ with one point identified. Let $X$ be $S^{1} \vee S^{2}$ as shown in Figure 13.12 and let $\tilde{X}$ be the universal covering of $X$. Note that although $H^{*}(X)$ :is finite, $H^{*}(\tilde{X})$ is infinite. We define a fiber bundle over the circle $S^{1}$ with fiber $\tilde{X}$ by setting.

$$
E=\tilde{X} \times I /(x, 0) \sim(s(x), 1)
$$

where $s$ is the deck transformation of the universal cover $\tilde{X}$ which shifts everything one unit up. The projection $\pi: E \rightarrow S^{1}$ is given by $\pi(\tilde{x}, t)=t$. The fundamental group of the base $\pi_{1}\left(S^{1}\right)$ acts on $H_{2}$ (fiber) by shifting each sphere one up.

Exercise 13.10. Find the homotopy type of the space $E$.

Figure 13.12

## CHAPTER III

## Spectral Sequences and Applications

This chapter begins with the abstract properties of spectral sequences and their relation to the double complexes encountered earlier. Then in Section 15 comes the crucial transition to integer coefficients. Many, but not all, of the constructions for the de Rham theory carry over to the singular theory. We point out the similarities and the differences whenever appropriate. In particular, there is a very brief discussion of the Künneth formula and the universal coefficient theorems in this new setting. Thereafter we apply the spectral sequences to the path fibration of Serre and compute the cohomology of the loop space of a sphere. The short review of homotopy theory. that follows includes a digression into Morse theory, where we sketch a proof that compact manifolds are $C W$ complexes. In connection with the computation of $\pi_{3}\left(S^{2}\right)$, we also discuss the Hopf invariant and the linking number and explore the rather subtle aspects of Poincare duality concerned with the boundary of a submanifold. Returning to the spectral sequences, we compute the cohomology of certain Eilenberg-MacLane spaces. The Eilenberg-MacLane spaces may be pieced together into a twisted product that approximates a given space. They are in this sense the basic building blocks of homotopy theory. As an application, we show that $\pi_{s}\left(S^{3}\right)=\mathbf{Z}_{2}$. We conclude with a very brief introduction to the rational homotopy theory of Dennis Sullivan. A more detailed overview of this chapter may be obtained by reading the introductions to the various eections. One word about the notation: for simplicity we often omit the coefficients from the cohomology groups. This should not cause any confusion, as $H^{*}(X)$ always denotes the de Rham cohomology except in Sections 15 through 18, where in the context of the gingular theory it stands for the singular cohomology.

## §14 The Spectral Sequence of a Filtered Complex

By considering the double complex $C\left(\mu, \Omega^{*}\right)$ of differential forms on an open cover, we generalized in Chapter II the key theorems of Chapter I. This double complex is a very degenerate case of an algebraic construction called the spectral sequence, a powerful tool in the computation of homology, cohomology and even homotopy groups. In this chapter we construct the spectral sequence of a filtered complex and apply it to a variety of situations, generalizing and reproving many previous results. Among the various approaches to the construction of a spectral sequence, perhaps the simplest is through exact couples, due to Massey [1].

## Exact Couples

An exact couple is an exact sequence of Abelian groups of the form

where $i, j$, and $k$ are group homomorphisms. Define $d: B \rightarrow B$ by $d=j \circ k$. Then $d^{2}=j(k j) k=0$, so the homology group $H(B)=($ ker $d) /(i m d)$ is defined. Here $A$ and $B$ are assumed to be Abelian so that the quotient $H(B)$ is a group.

Out of a given exact couple we can construct a new exact couple, called the derived couple,

by making the following definitions.
(a) $\cdot A^{\prime}=i(A) ; B^{\prime}=H(B)$.
(b) $f$ is induced from $i$; to be precise,

$$
i^{\prime}(i a)=i(i a)
$$

(c) If $a^{\prime}=i a$ is in $A^{\prime}$, with $a$ in $A$, then $j^{\prime} a^{\prime}=[j a]$, where [ ] denotes the homology class in $H(B)$. To show that $j^{\prime}$ is well-defined we have to check two things:
(i) $j a$ is a cycle. This follows from $d(j a)=j(k j) a=0$.
(ii) The homology class [ja] is independent of the choice of $a$.

Suppose $a^{\prime}=i \bar{a}$ for some other $\bar{a}$ in $A$. Then because $0=i(a-\bar{a})$, we have $a-\bar{a}=k b$ for some $b$ in $B$. Thus

$$
j a-j \bar{a}=j k b=d b
$$

so

$$
[j a]=[j \bar{a}]
$$

(d) $k^{\prime}$ is induced from $k$. Let $[b]$ be a homology class in $H(B)$. Then $j k b=0$ so that $k b=i a$ for some $a$ in $A$. Define

$$
k^{\prime}[b]=k b \in i(A) .
$$

It is straightforward to check that with these definitions, (14.1) is an exact couple. We will check the exactness at $B^{\prime}$ and leave the other steps to the reader.
(i) im $j^{\prime} \subset \operatorname{ker} k^{\prime}$ :

$$
k^{\prime} j^{\prime}\left(a^{\prime}\right)=k^{\prime} j^{\prime}(i a)=k^{\prime} j(a)=k j(a)=0 .
$$

(ii) $\operatorname{ker} k^{\prime} \subset \operatorname{im} j^{\prime}$ :

Since $k^{\prime}(b)=k(b)=0$, it follows that $b=j(a)=j^{\prime}(i a) \in \operatorname{im} j^{\prime}$.

## The Spectral Sequence of a Filtered Complex

Let $K$ be a differential complex with differential operator $D$; i.e., $K$ is an Abelian group and $D: K \rightarrow K$ is a group homomorphism such that $D^{2}=0$. Usually $K$ comes with a grading $K=\bigoplus_{k \in Z} C^{k}$ and $D: C^{k} \rightarrow C^{k+1}$ increases the degree by 1 , but the grading is not absolutely indispensable. A subcomplex $K^{\prime}$ of $K$ is a graded subgroup such that $D K^{\prime} \subset K^{\prime}$. A sequence of subcomplexes

$$
K=K_{0} \supset K_{1} \supset K_{2} \supset K_{3} \supset \cdots
$$

is called a filtration on $K$. This makes $K$ into a filtered complex, with associated graded complex

$$
G K=\bigoplus_{p=0}^{\infty} K_{p} / K_{p+1}
$$

For notational reasons we usually extend the filtration to negative indices by defining $K_{p}=K$ for $p<0$.

Example 14.2. If $K=\bigoplus K^{\text {p. } q}$ is a double complex with horizontal operator $\delta$ and vertical operator $d$, we can form a single complex out of it in the usual way, by letting $K=\bigoplus C^{k}$, where $C^{k}=\bigoplus_{p+q=k} K^{p . q}$, and defining the differential operator $D: C^{\star} \rightarrow C^{k+1}$ to be $D=\delta+(-1)^{p} d$. Then the sequence of subcomplexes indicated below is a filtration on $K$ :

$$
K_{p}=\bigoplus_{i \geq p} \bigoplus_{q \geq 0} K^{i . q}
$$

Returning to the general filtered complex $K$, let $A$ be the group

$$
A=\bigoplus_{p \in \Sigma} K_{p} .
$$

$A$ is again a differential complex with operator $D$. Define $i: A \rightarrow A$ to be the inclusion $K_{p+1} \hookrightarrow K_{p}$ and define $B$ to be the quotient

$$
\begin{equation*}
0 \rightarrow A \xrightarrow{\prime} A \xrightarrow{\prime} B \rightarrow 0 . \tag{14.3}
\end{equation*}
$$

Then $B$ is the associated graded complex $G K$ of $K$. In the short exact sequence (14.3) each group is a complex with operator induced from $D$. From this short exact sequence we get a long exact sequence of cohomology groups

$$
\cdots \rightarrow H^{k}(A) \xrightarrow{t_{1}} H^{k}(A) \xrightarrow{h_{1}} H^{k}(B) \xrightarrow{k_{1}} H^{k+1}(A) \rightarrow \cdots,
$$

which we may write as

where the map $i$ is no longer an inclusion. We suppress the subscript of $i_{1}$ to
avoid cumbersome notation later. Since this is an exact couple, it gives rise as in (14.1) to a sequence of exact couples:

each being the derived couple of its predecessor.
For the sake of the exposition consider now the case where the filtered complex terminates after $K_{3}$ :

$$
\cdots=K_{-1}=K_{0} \supset K_{1} \supset K_{2} \supset K_{3} \supset 0
$$

Then $A_{1}$ is the direct sum of all the terms in the following sequence

$$
\cdots \approx H(K) \approx H(K) \leftarrow H\left(K_{1}\right) \leftarrow H\left(K_{2}\right) \stackrel{i}{\leftarrow} H\left(K_{3}\right) \leftarrow 0 .
$$

This is of course not an exact sequence. Next, $\boldsymbol{A}_{2}$ by definition is the image of $A_{1}$ under $i$ in $A_{1}$ and so is the direct sum of the groups in the sequence

$$
\cdots \simeq H(K) \approx H(K) \supset i H\left(K_{1}\right) \leftarrow i H\left(K_{2}\right) \leftarrow i H\left(K_{3}\right) \leftarrow 0 .
$$

Note that here the map $i H\left(K_{1}\right) \subset H(K)$ is an inclusion. Similarly $A_{3}$ is the sum of

$$
\cdots \simeq H(K) \approx H(K) \supset i H\left(K_{i}\right) \supset i i H\left(K_{2}\right) \leftarrow i i H\left(K_{3}\right) \leftarrow 0
$$

and $A_{4}$ is the sum of

$$
\simeq H(K) \simeq H(K) \supset i H\left(K_{1}\right) \supset i i H\left(K_{2}\right) \supset i i i H\left(K_{3}\right) \supset 0 .
$$

Since all the maps become inclusions in $A_{4}$, all the $A$ 's are stationary after the fourth derived couple:

$$
A_{4}=A_{5}=A_{6}=\cdots=A_{\infty}
$$

Furthermore, since

is exact and $i: A_{4} \rightarrow A_{4}$ is the inclusion, the map $k_{4}: B_{4} \rightarrow A_{4}$ must be the
zero map. Therefore, after the fourth stage all the differentials of the exact couples are zero and the $B$ 's also become stationary,

$$
B_{4}=B_{5}=B_{6}=\cdots=B_{\infty} .
$$

In the exact couple

$A_{\infty}$ is the direct sum of the groups

$$
\begin{equation*}
\cdots=H(K)=H(K) \supset i H\left(K_{1}\right) \supset i i H\left(K_{2}\right) \supset i i i H\left(K_{3}\right) \supset 0 \tag{14.4}
\end{equation*}
$$

and the inclusion $i_{\infty}$ is as in (14.4). Since $B_{\infty}$ is the quotient of $i_{\infty}$, it is the direct sum of the successive quotients in $i_{\infty}$. If we let (14.4) be the filtration on $H(K)$, then $B_{x}$ is the associated graded complex of the filtered complex $H(K)$.

We now return to the general case. The sequence of subcomplexes

$$
\cdots=K=K \supset K_{1} \supset K_{2} \sqsupset K_{3} \supset \cdots
$$

induces a sequence in cohomology

$$
\cdots \subsetneq H(K) \subsetneq H(K) \leftarrow H\left(K_{1}\right) \leftarrow H\left(K_{2}\right) \leftarrow H\left(K_{3}\right) \leftarrow \cdots,
$$

where the maps $i$ are of course no longer inclusions. Let $F_{p}$ be the image of $H\left(K_{p}\right)$ in $H(K)$. Then there is a sequence of inclusions

$$
\begin{equation*}
H(K)=F_{0} \supset F_{1} \supset F_{2} \supset F_{3} \supset \cdots, \tag{14.5}
\end{equation*}
$$

making $H(K)$ into a filtered complex; this filtration is called the induced filtration on $H(K)$.

A filtration $K$, on the filtered complex $K$ is said to have length $/$ if $K_{p}=0$ for $p>\ell$. By the same argument as the special case above, we see that whenever the filtration on $K$ has finite length, then $A_{r}$ and $B_{r}$ are eventually stationary and the stationary value $B_{\infty}$ is the associated graded complex $\oplus F_{\alpha} / F_{p+1}$ of the filtered complex $H(K)$ with filtration given by (14.5).

It is customary to write $E_{r}$ for $B_{r}$. Hence,

$$
\begin{aligned}
& E_{1}=H(B) \text { with differential } d_{1}=j_{1} \circ k_{1}, \\
& E_{2}=H\left(E_{1}\right) \text { with differential } d_{2}, \\
& E_{3}=H\left(E_{2}\right), \text { etc. }
\end{aligned}
$$

A sequence of differential groups $\left\{E_{r}, d_{r}\right\}$ in which each $E_{\text {, }}$ is the homology of its predecessor $E_{r-1}$ is callod a spectral sequence. If $E_{r}$ eventually bo-
comes stationary, we denote the stationary value by $E_{\infty}$, and if $E_{\infty}$ is equal to the associated graded group of some filtered group $H$, then we say that the spectral sequence converges to $H$.

Now suppose the filtered complex $K$ comes with a grading: $K=$ $\oplus_{n \in \mathcal{I}} K^{n}$. To distinguish the grading degree $n$ from the filtration degree $p$, we will often call $n$ the dimension. The filtration $\left\{K_{p}\right\}$ on $K$ induces a filtration in each dimension: if $K_{p}^{n}=K^{n} \cap K_{p}$, then $\left\{K_{p}^{n}\right\}$ is a filtration on $K^{n}$.

For the applications we have in mind, the filtration on $K$ need not have finite length. However, we can prove the following.

Theorem 14.6. Let $K=\oplus_{n \in 2} K^{n}$ be a graded filtered complex with filtration $\left\{K_{p}\right\}$ and let $H_{b}^{*}(K)$ be the cohomology of $K$ with filtration given by (14.5). Suppose for each dimension $n$ the filtration $\left\{K_{p}^{*}\right\}$ has finite length. Then the short exact sequence

$$
0 \rightarrow \oplus K_{p+1} \rightarrow \oplus K_{p} \rightarrow \oplus K_{p} / K_{p+1} \rightarrow 0
$$

induces a spectral sequence which converges to $H_{D}^{*}(K)$.
Proof. By treating the convergence question one dimension at a time, this proof reduces to the ungraded situation. To be absolutely sure, we will write out the details. As before,

$$
A_{r}=\oplus_{p \in Z} r^{-1} H\left(K_{p}\right) ;
$$

if $r \geq p+1$, then $i^{r} H\left(K_{p}\right)=F_{p}$, and

$$
i: i^{r} H\left(K_{p+1}\right) \rightarrow i^{r} H\left(K_{p}\right)
$$

is an inclusion. With a grading on each derived couple, $i$ and $j$ preserve the dimension, but $k$ increases the dimension by 1 . Given $n$, let $l(n)$ be the length of $\left\{K_{p}^{\prime \prime}\right\}$, . 2 and let $r \geq \ell(n+1)+1$. Then for any integer $p$,

$$
i^{\prime} H^{n+1}\left(K_{p+1}\right)=F_{p+1}^{n+1}
$$

and

$$
i: i^{r} H^{p+1}\left(K_{p+1}\right) \rightarrow i^{r} H^{n+1}\left(K_{p}\right)
$$

is an ipclusion. It follows that

$$
i_{i}: A_{p}^{n+1} \rightarrow A_{p}^{n+1}
$$

is an inclusion and

$$
k_{r}: B_{r}^{n} \rightarrow A_{r}^{n+1}
$$

is the zero map. Therefore, as $r \rightarrow \infty$, the group $B_{r}^{\mu}$ becomes stationary and we can define $B_{\infty}^{3}$ to be this stationary value. Note that

$$
A_{\infty}^{n}=\oplus F_{p}^{*}
$$

and that $i_{\infty}$ sends $F_{p+1}^{n}$ into $F_{p}^{n}$ for every $n$. Because $i_{\infty}: \bigoplus F_{p+1} \rightarrow \bigoplus F_{p}$ is an inclusion, $B_{\infty}$ is the associated graded complex $\bigoplus F_{\phi} / F_{p+1}$ af $H_{b}^{*}(K)$.

## The Spectral Sequence of a Double Complex

Now let $K=\bigoplus K^{p . q}$ be a double complex with the filtration of Example 14.2. We will obtain a refinement of Theorem 14.6 for this special case by taking into account not only the particular filtration in question but also the bigrading and the presence of the two differential operators $\delta$ and $d$. The direct sum $A=\oplus K_{p}^{\prime}$ is also a double complex. Here, as always, we form a single complex $A=\oplus A^{k}$ out of this double complex by summing the bidegrees: $A^{k}$ consists of all elements in $A$ whose total degree is $k$. There is an inclusion $i: A^{k} \rightarrow A^{k}$ given by

$$
i: A^{k} \cap K_{p+1} \rightarrow A^{k} \cap K_{p} .
$$

The single complex $A$ inherits the differential operator $D=\delta+(-1)^{\text {P }} d$ from $K$.

Similarly, $B=\bigoplus K_{p} / K_{p+1}$ can be made into a single complex with operator $D$. Note that the differential operator $D$ on $B$ is $(-1)^{p} d$; therefore,

$$
\begin{equation*}
E_{1}=H_{D}(B)=H_{d}(K) . \tag{14.7}
\end{equation*}
$$

Recall that the coboundary operator $k_{1}: H(B) \rightarrow H(A)$ is the coboundary operator of the short exact sequence (14.3) and hence is defined by the following diagram:

Let $b$ in $A^{k} \cap K_{p}$ represent a cocycle [b] in $B^{k} \cap K_{p} / K_{p+1}$. This corrosponds to Step (1) in the diagram. To get $\boldsymbol{k}_{\mathrm{t}}([b])$, we
(2) compute $D b$ and
(3) take its inverse under $i$.

Since $b$ represents an element of $E_{1}=H_{D}(B)=H_{d}(K), d b=0$ and $D b=\delta b+(-1)^{p} d b=\delta b$. Thus $k_{1}[b]=[\delta b] ; s 0$ the differential $d_{1}=j_{1} k_{1}$
on $E_{1}$ is given by $\delta$ (in fact by $D$, but $D=\delta$ on $E_{1}$ ). Consequently

$$
\begin{equation*}
E_{2}=H_{3} H_{d}(K) . \tag{14.9}
\end{equation*}
$$

We now compute the differential $d_{2}$ on $E_{2}$. As noted in the proof of Proposition 12.1, an element of $E_{2}=H_{d} H_{4}(K)$ is represented by an element $b$ in $K$ such that
$d b=0$
$\delta b=-D^{\prime \prime} c$ for some $c$ in $K$,

where $D^{n}=(-1)^{\prime} d$. We will denote the class of $b$ in $E_{p}$, if it is defined, by $[b]_{\text {. }}$. From the definition of the derived couple (14.1),

$$
d_{2}[b]_{2}=j_{2} k_{2}[b]_{2}=j_{2} k_{1}[b]_{1}
$$

To compute $j_{2} k_{1}[b]_{1}$, we must find an $a$ such that $k_{1}[b]_{1}=i[a]_{1}$. Then $j_{2} k_{2}[b]_{2}=\left[j_{1} a\right]_{2}$. Since $k_{1} b$ is in $A^{k+1} \cap K_{p+1}, a$ is in $A^{k+1} \cap K_{p+2}$. To find $a$ we use not $b$ but $b+c$ in $A^{k} \cap K_{p}$ to represent $[b]_{2}$ in Step (1); this is possible since $b$ and $b+c$ have the same image under the projection $K_{p} \rightarrow K_{p} / K_{p+1}$. Then

$$
k_{1}(b+c)=D(b+c)=\delta c .
$$

So

$$
\begin{equation*}
d_{2}[b]_{2}=[\delta c]_{2} \tag{14.10}
\end{equation*}
$$

Thus the differential $d_{2}$ is given by the $\delta$ of the tail of the zig-zag which extends $b$. It is easy to show that $\delta c$ represents an eiement of $H_{d} H_{d}(K)$ and that the definition of $d_{2}[b]_{2}$ is independent of the choice of $c$.

Exercise 14.11. Show that if $d_{2}[b]_{2}=0$, then there exist $c_{1}$ and $c_{2}$ so that $b$ can be extended to a zig-zag as shown:

$$
\begin{aligned}
D^{\prime \prime} b & =0 \\
\delta b & =-D^{\prime \prime} c_{1} \\
\delta c_{1} & =-D^{\prime \prime} c_{2}
\end{aligned}
$$

We say that an element $b$ in $K$ lives to $E_{F}$ if it represents a cohomology class in $E_{r}$; equivalently, $b$ is a cocycle in $E_{1}, E_{2}, \ldots, E_{r-1}$. From the discussion above we see that $b$ lives to $E_{2}$ if it can be extended to a zig-zag of length 2 , the length of a zig-zag being the number of terms in it,

$$
\begin{aligned}
& d b=0 \\
& \delta b=-D^{\prime \prime} c
\end{aligned}
$$

and $d_{2}[b]_{2}=[\delta c]_{2}$; it lives to $E_{3}$ if.it: can be: extended to a zig-zag of length 3:

$$
\begin{aligned}
& d b=0 \\
& \delta b=-D^{\prime \prime} c_{1} \\
& \delta c_{1}=-D^{\prime \prime} c_{2}
\end{aligned}
$$

To compute $d_{3}[b]_{3}$, we use $b+c_{1}+c_{2}$ in $A^{k} \cap K_{p}$ to represent $[t] \in$ $B^{k} \cap\left(K_{p} / K_{p-1}\right)$ in Step (1) of (14.8), so that $k_{3}[b]_{3}$ is given by $D(b+$ $\left.c_{1}+c_{2}\right)=\delta c_{2}$ and $d_{3}[b]_{3}=\left[\delta c_{2}\right]_{3}$. In general, parallel to the discussion above, an element $b$ in $K^{p . e}$ lives to $E_{r}$ if it can be extended to a zig-zag of length $r$ :

and the differential $d_{r}$ on $E_{r}$ is given by $\delta$ of the tail of the zig-zag:

$$
\begin{equation*}
d_{r}[b]_{r}=\left[\delta c_{r-1}\right]_{r} \tag{14.12}
\end{equation*}
$$

Thus the bidegrees $(p, q)$ of the double complex $K=\oplus K^{p . q}$ persist in the spectral sequence

$$
E_{r}=\bigoplus_{p, q} E_{r}^{p, 4},
$$

and $d_{r}$ shifts the bidegrees by $(r,-r+1)$ :

$$
d_{r}: E_{r}^{p, q} \rightarrow E_{r}^{p+r, q-r+1}
$$

The filtration on $H(K)=\oplus H^{r}(K)$ :

$$
H(K)=F_{0} \supset F_{1} \supset F_{2} \supset \cdots
$$

induces a filtration on each component $H^{n}(K)$, the successive quotients of . the filtration being $E_{\infty}^{0, n}, E_{\infty}^{1, n-1}, \ldots, E_{\infty}^{n, 0}$ :

$$
\begin{equation*}
H^{n}(K)=(F_{0} \cap \underbrace{\left.H^{n}\right) \supset\left(F_{1}\right.}_{E_{\infty}^{0, n}} \cap \underbrace{\left.H^{\prime \prime}\right) \supset\left(F_{2}\right.}_{E_{\infty}^{1, n-1}} \cap H^{n}) \supset \ldots \supset\left(F_{n} \cap H_{\left.H^{n}\right) \supset 0}^{E_{\infty}^{n, 0}}\right. \tag{14.13}
\end{equation*}
$$

This is best seen pictorially

In summary, we have proved the following refinement of Theorem 14.6.
Theorem 14.14. Given a double complex $K=\oplus_{p, 9 \geq 0} K^{p, 8}$ there is a spectral sequence $\left\{E_{r}, d_{r}\right\}$ converging to the total cohomology $H_{D}(K)$ such that each $E_{p}$ has a bigrading with

$$
d_{r}: E_{r}^{p, q} \rightarrow E_{r}^{p+r, e-r+1}
$$

and

$$
\begin{aligned}
& E \rho^{9}=H \zeta^{-q}(K), \\
& E_{2}^{p}{ }^{4}=H \xi^{\cdot} \cdot H_{d}(K) ;
\end{aligned}
$$

furthermore, the associated graded complex of the total cohomology is given by

$$
G H_{D}^{n}(K)=\bigoplus_{p+q-\infty} E_{\infty}^{p} a(K)
$$

Remark 14.15. Of course, instead of the filtration in Example 14.2, we could just as well have given $\boldsymbol{K}$ the following filtration.

This gives a second spectral sequence $\left\{E_{r}^{\prime}, d_{r}^{\prime}\right\}$ converging to the total cohomology $H_{D}(K)$, but with

$$
\begin{aligned}
& E_{1}^{\prime}=H_{\delta}(K), \\
& E_{2}^{\prime}=H_{d} H_{\delta}(K),
\end{aligned}
$$

and

$$
d_{r}^{\prime}: E_{r}^{\prime p \cdot \varphi} \rightarrow E_{r}^{\prime p-r+1, q+r}
$$

Example 14.16 (The Mayer-Vietoris principle and the isomorphism between de Rham and Cech). Let $M$ be a manifold and $u$ a good cover on $M$. Consider the double complex $K=\bigoplus K^{p, q}$,

$$
K^{p, q}=C^{p}\left(\mathfrak{U}, \Omega^{q}\right)=\prod_{\overline{0}_{0}<} \Omega^{q}\left(U_{\alpha_{0} \ldots a_{p}}\right)
$$

Since the rows of $K$ are the Mayer-Vietoris sequences, the $E_{1}$ term of the second spectral sequence is

$$
E_{1}^{\prime}=H_{d}=\left[\begin{array}{lll|l|l|} 
& & \\
& & \\
\Omega^{3}(M) & 0 & & \\
\Omega^{2}(M) & 0 & & \\
\Omega^{1}(M) & 0 & & \\
\Omega^{0}(M) & 0 & & \\
\hline
\end{array}\right.
$$

Therefore the $E_{2}$ term is

$$
E_{2}^{\prime}=H_{d} H_{\mathrm{d}}=\left\lvert\, \begin{array}{ll|l|l|l} 
& & & \\
H_{D R}^{3}(M) & 0 & & \\
H_{D R}^{2}(M) & 0 & & \\
H_{D R}^{1}(M) & 0 & & \\
H_{D R}^{0}(M) & 0 & & \\
\hline
\end{array}\right.
$$

In general a spectral sequence is said to degenerate at the $E_{r}$ term if $d_{r}=$ $d_{r+1}=\cdots=0$. For such a spectral sequence $E_{r}=E_{r+1}=\cdots=E_{\infty}$. The degeneration of the second spectral sequence of the double complex
$C^{*}\left(\mathcal{U}, \Omega^{*}\right)$ at the $E_{2}$ term proves once again the Mayer-Vietoris principle (Proposition 8.8):

$$
\begin{equation*}
H_{D A}^{k}(M)=\underset{\rho+q=k}{ } H_{D}^{\ell}\left\{C^{\star}\left(U, \Omega^{\star}\right)\right\} \tag{14.16.1}
\end{equation*}
$$

Now consider the first spoctral sequence of $C^{*}\left(\mathfrak{U}, \Omega^{*}\right)$. Its $E_{1}$ term is

$$
E_{1}^{p . q}=\prod_{\alpha_{0}<\ldots<\alpha_{p}} H^{q}\left(U_{\alpha_{0} \ldots \alpha_{0}}\right)= \begin{cases}0 & \text { if } q>0 \\ C^{p}(\mathbb{U}, \mathbb{R}) & \text { if } q=0\end{cases}
$$

$$
\left.E_{\mathrm{i}}=H_{d}=\left\lvert\, \begin{array}{cc|c|c} 
& & \\
& & & \\
& & & \\
0 & 0 & 0 \\
C^{0}(\mathbf{U}, \mathbf{R}) & C^{1}(\mathbf{U}, \mathbf{R}) & C^{\mathbf{2}}(\mathbf{U}, \mathbf{R})
\end{array}\right.\right]
$$

So the $E_{2}$ term is

The degeneration of this spectral sequence gives

Together with (14.16.1) we get

$$
H_{D R}^{k}(M)=H^{k}(\mathcal{U}, \mathrm{R}) \quad \text { for all integers } k \geq 0
$$

This is the spectral sequence proof of the isomorphism berween de Rham and Cech (Theorem 8.9).

Remark 14.17. The extension problem. Because the dimension is the only invariant of a vector space, the associated graded vector space $G V$ of a filtered vector space $V$ is isomorphic to $V$ itself. In particular, if the doable complex $K$ is a vector space, then

$$
H_{D}^{\prime \prime}(K) \simeq G H_{D}^{\prime}(K) \simeq \bigoplus_{p+\infty=\sim} E_{\infty}^{p_{i}}
$$

However, in the realm of Abelian groups a knowledge of the associated graded group does not determine the group itself. For example, the two groups $\mathbf{Z}_{2} \oplus \mathbf{Z}_{2}$ and $\mathbf{Z}_{4}$ filtered by

$$
\mathbf{Z}_{2} \subset \mathbf{Z}_{2} \oplus \mathbf{Z}_{2}
$$

and

$$
\mathbf{Z}_{2} \subset \mathbf{Z}_{4}
$$

have isomorphic associated graded groups, but $\mathbf{Z}_{\mathbf{2}} \oplus \mathbf{Z}_{\mathbf{2}}$ is not isomorphic to $\mathbb{Z}_{4}$. Put another way, in a short exact sequence of Abelian groups

$$
0 \rightarrow A \rightarrow B \rightarrow C \rightarrow 0,
$$

$A$ and $C$ do not determine $B$ uniquely. The ambiguity is called the extension problem and lies at the heart of the subject known as homological algebra. For our purpose it suffices to be familiar with the following elementary facts from extension theory.

Proposition 14.17.1. In a short exact sequence of Abelian groups

$$
0 \rightarrow A \xrightarrow{f} B \xrightarrow{\prime} C \rightarrow 0,
$$

if $A$ and $C$ are free, then there exists a homomorphism s: $C \rightarrow B$ such that $g \circ s$ is the identity on $C$.

Proor. Define $s$ appropriately on the generators of $C$ and extend linearly.

Corollary 14.17.2. Under the hypothesis of the proposition,
(a) the $\operatorname{map}(f, s): A \oplus C \rightarrow B$ is an isomorphism;
(b) for any Abelian group $G$ the induced sequence

$$
0 \rightarrow \operatorname{Hom}(C, G) \rightarrow \operatorname{Hom}(B, G) \rightarrow \operatorname{Hom}(A, G) \rightarrow \cap
$$

is exact;
(c) for any Abelian group $G$ the sequence

$$
0 \rightarrow A \otimes G \rightarrow B \otimes G \rightarrow C \otimes G \rightarrow 0
$$

is exact.
The proof is left to the reader.
Exercise 14.17.3. Show that if

$$
0 \rightarrow A_{1} \rightarrow A_{2} \rightarrow A_{3} \rightarrow \cdots
$$

$s$ an exact sequence of free Abelian groups and if $G$ is any Abelian group,
then the two sequences

$$
0 \leftarrow \operatorname{Hom}\left(A_{1}, G\right) \leftarrow \operatorname{Hom}\left(A_{2}, G\right) \leftarrow \operatorname{Hom}\left(A_{3}, G\right) \leftarrow \cdots
$$

and

$$
0 \rightarrow A_{1} \otimes G \rightarrow A_{2} \otimes G \rightarrow A_{3} \otimes G \rightarrow \cdots
$$

are both exact.
Exercise 14.17.4. Show that if

$$
0 \rightarrow A \rightarrow B \rightarrow C \rightarrow 0^{0}
$$

is a short exact sequence of Abelian groups (which are not necessarily froe) and $G$ is any Abelian group, then the two sequences

$$
0 \rightarrow \operatorname{Hom}(C, G) \rightarrow \operatorname{Hom}(B, G) \rightarrow \operatorname{Hom}(A, G)
$$

and

$$
A \otimes G \leftarrow B \otimes G \leftarrow C \otimes G \leftarrow 0
$$

are both exact.

## The Spectral Sequence of a Fiber Bundle

Let $\pi: E \rightarrow M$ be a fiber bundle with fiber $F$ over a manifold $M$. Applying Theorem 14.14 here gives a general method for computing the cohomology of $E$ from that of $F$ and $M$. Indeed, given a good cover $\mathcal{U}$ of $M, \pi^{-1} \mathfrak{U}$ is a cover on $E$ and we can form the double complex
whose $E_{1}$ term is
where $\mathscr{H}^{a}$ is the presheaf $\mathscr{H}^{q}(U)=H^{q}\left(\pi^{-1} U\right)$ on $M$. For emphasis we sometimes write the presheaf $\mathscr{X}^{4}$ as $\mathscr{X}^{4}(F)$. Since $\mathcal{U}^{4}$ is good cover, $\mathscr{X}^{\prime \prime}$ is a locally constant presheaf on $\mathfrak{U}$ with group $H^{4}(F)$ (Example 10.1). Since $d_{1}=\delta$ on $E_{1}$, the $E_{2}$ term is

$$
E_{\varepsilon^{\rho \cdot 4}}^{q^{4}} H \xi\left(u, x^{\eta}\right) .
$$

By Theorem 14.14 the spectral sequence of $K$ converges to $H_{D}\left(K^{( }\right)$, which by the Mayer-Vietoris principle is equal to $H^{\boldsymbol{*}}(E)$, because $\pi^{-\boldsymbol{1}} \boldsymbol{U}$ is a cover on E.

In case the base $M$ is simply connected and $H^{4}(F)$ is finite-dimensional, Theorems 13.2 and 13.4 imply that $\mathscr{W}^{\circ}$ is the constant presheaf $\mathbf{R} \oplus \cdots$ $\oplus \mathbb{R}$ on $\mathfrak{U}$, consisting of $h^{4}(F)$ copies of $\mathbf{R}$ where $h^{4}(F)=\operatorname{dim} H^{4}(F)$. So the
$E_{E^{p, 9}}{ }^{9}$ term is isomorphic as a vector space to the tensor product $H^{p}(M) \otimes$ $H^{q}(F)$, since

$$
\begin{aligned}
E_{2}^{\rho, q}=H^{p}(\mathcal{U}, \mathbb{R} \oplus \cdots \oplus \mathbb{R}) & =H^{p}(\mathfrak{U}, \mathbb{R}) \otimes H^{q}(F) \\
& =H^{p}(M) \otimes H^{q}(F),
\end{aligned}
$$

where the last equality follows from Theorem 8.9.
We have proven the following.
Theorem 14.18 (Leray's Theorem for de Rham Cohomology). Given a fiber bundle $\pi: E \rightarrow M$ with fiber $F$ over a manifold $M$ and a good cover $\mathfrak{U}$ of $M$, there is a spectral sequence $\left\{E_{r}\right\}$ converging to the cohomology of the total space $H^{*}(E)$ with $E_{2}$ term

$$
E_{2}^{p, q}=H^{p}\left(\amalg, \mathscr{H}^{q}\right),
$$

where $\mathscr{H}^{a}$ is the locally constant presheaf $\mathscr{H}^{q}(U)=H^{q}\left(\pi^{-1} U\right)$ on $\mathbb{U}$. If $M$ is simply connected and $H^{q}(F)$ is finite-dimensional, then

$$
E \sum_{2}^{p} q^{q}=H^{p}(M) \otimes H^{q}(F) .
$$

## Some Applications

Example 14.19 (The Künneth formula and the Leray-Hirsch theorem). We now give a spectral sequence proof of the Künneth formula (5.9). Let $M$ and $F$ be two manifolds and $\boldsymbol{U}$ a good cover of $M$. Suppose $F$ has finitedimensional cohomology. By Leray's theorem (14.18), the spectral sequence of the trivial bundle

has $E_{2}$ term

$$
E_{2}^{p, 4}=H^{p}\left(\mathbb{U}, \mathscr{H}^{q}(F)\right) .
$$

Because $M \times F$ is a trivial bundle over $M$, the presheaf $\mathscr{H}^{q}(F)$ is constant, so that

$$
E_{2^{p}, q}^{p}=H^{p}(\mathfrak{U}, \mathbf{R}) \otimes H^{q}(F)=H^{p}(M) \otimes H^{q}(F)
$$

By (14.12) the differential $d_{r}$ measures the extent to which an element of $C^{*}\left(\pi^{-1} \mathbf{U}, \Omega^{*}\right)$ that lives to $E_{r}$ fails to be extended one step further to a D-cocycle. Since every element of the $E_{2}$ term is already a global form on
$M \times F, d_{2}=d_{3}=\cdots=0$. So $\dot{E}_{2}=E_{\infty}$, which by Theorem 14.18 is $H^{*}(M \times F)$. Therefore we have the Künneth formula

$$
H^{*}(M \times F)=H^{*}(M) \otimes H^{*}(F) .
$$

The proof of the Leray-Hirsch theorem is analogous.
Remark 14.20 (Orientability and the Euler class of a sphere bundle). Let $\pi: E \rightarrow M$ be an $S^{n}$-bundle over a manifold $M$ and let $\mathcal{U}$ be a good cover of $M$. The spectral sequence of this fiber bundle has

Let $\sigma$ be the element of $E_{1}^{0 . n}=C^{0}\left(\mathfrak{U}, \mathscr{H}^{n}\left(S^{n}\right)\right)$ corresponding to the local angular forms on the sphere bundle $E$. From the description of the differential $d_{r}$ as the $\delta$ of the tail of a zig-zag, we see that $E$ is orientable if and only if $d_{1} \sigma=0$ (compare with pp. 116-118). For: an orientable $S^{n}$-bundle then, such a $\sigma$ lives to $E_{n}$ :

Up to a sign $d_{n} \sigma$ in $H^{n+1}\left(\mu, \mathscr{K}^{0}\left(S^{n}\right)\right)=H^{n+1}(M)$ is the Euler class of the sphere bundle. It measures the extent to which $\sigma$ fails to be extended to a D-cocycle, i.e., a global closed $n$-form on the sphere bundie.

Example 14.21 (Orientability of a simply connected manifold). Let $M$ be a simply connected manifold of dimension $n$ and $S\left(T_{m}\right)$ its unit tangent
bundle. The spectral sequence of the fiber bundle

has $E_{2}$ term

This shows that there is an element in $C^{0}\left(\pi^{-1} \mathfrak{U}, \mathscr{H}^{n-1}\right)$ which can be extended one step down toward being a $D$-cocycle. Therefore $S\left(T_{M}\right)$ and also $M$ are orientable. This gives an alternative proof of the orientability of a simply connected manifold (Corollary 11.6).

Example 14.22 (The cohomology of the complex projective space). Consider the sphere

$$
S^{2 n+1}=\left\{\left.\left(z_{0}, \ldots, z_{n}\right)| | z_{0}\right|^{2}+\cdots+\left|z_{n}\right|^{2}=1\right\}
$$

in $C^{n+1}$. Let $S^{1}$ act on $S^{2 n+1}$ by

$$
\left(z_{0}, \ldots, z_{n}\right) \mapsto\left(\lambda z_{0}, \ldots, \lambda z_{n}\right)
$$

where $\lambda$ in $S^{1}$ is a complex number of absolute value 1 . The quotient of $S^{2 n+1}$ by this action is the complex projective space CP ${ }^{n}$. This gives $S^{2 n+1}$ the structure of a circle bundle over CP ${ }^{m}$

As we will see from the homotopy exact sequence (17.4) to be discussod later, CP ${ }^{\text {w }}$ is simply connected. Thus

$$
E \tilde{\zeta}^{p} \cdot q=H^{p}\left(C P^{q}\right) \otimes H^{q}\left(S^{1}\right) .
$$

So $E_{2}$ has only two nonzero rows, $q=0,1$, and the two rows are identical; both being $\left.H^{*}(\mathbb{C P})^{*}\right)$.

Let $n=2$. Then
where the bottom row is the cohomology of the base, $H^{*}\left(C P^{2}\right)$, and the 0 -th column is the cohomology of the fiber. $H^{P}\left(\mathbf{C P}^{2}\right)=0$ for $p \geq 5$ because $C P^{2}$. has dimension 4. Since $d_{3}$ moves down two steps, $d_{3}=0$. Similarly,

$$
d_{4}=d_{5}=\cdots=0 .
$$

So the spectral sequence degenerates at the $E_{3}$ term and $E_{3}=E_{4}=\cdots=$ $E_{\infty}=H^{*}\left(S^{5}\right)$. Therefore

$$
E_{3}=\frac{\begin{array}{l|l|l|l|l|l|l|} 
& & & & & & \\
0 & 0 & 0 & 0 & \mathbf{R} & 0 & \\
\mathbf{R} & 0 & 0 & 0 & 0 & 0 & \\
\hline
\end{array}}{\begin{array}{ll}
1 & 2
\end{array} \mathbf{3} 4}
$$

This means

$$
\begin{aligned}
d_{2}: & R \\
& \rightarrow B, \quad B \rightarrow D, \\
0 & \rightarrow A, \quad A \rightarrow C, \quad C \rightarrow 0
\end{aligned}
$$

must all be isomorphisms. It follows that

$$
E_{2}=\begin{array}{l|l|l|l|l|l|l|l} 
& \begin{array}{l|l|l|l|l|l|l}
\mathbf{R} & 0 & \mathbf{R} & 0 & \mathbf{R} & 0 & \\
\mathbf{R} & 0 & \mathbf{R} & 0 & \mathbf{R} & 0 & \\
\hline 0 & 1 & 2 & 3 & 4
\end{array} \\
\hline
\end{array}
$$

Therefore,

$$
H^{*}\left(C P^{2}\right)= \begin{cases}R & \text { in dimensions } 0,2,4 \\ 0 & \text { otherwise. }\end{cases}
$$

Exercise 14.22.I. Show that

$$
H^{*}\left(C P^{\prime \prime}\right)= \begin{cases}R & \text { in dimensions } 0,2,4, \ldots, 2 n \\ 0 & \text { otherwise } .\end{cases}
$$

Exercise 14.23 (Algebraic Künneth Formula). Let $E$ and $F$ be graded differential algebras over $\mathbf{R}$ with differential operators $\delta$ and $d$ respectively. Define a differential operator $D$ on the tensor product $E \otimes F$ by

$$
D(e \otimes f)=(\delta e) \otimes f+(-1)^{\operatorname{dec} e} e \otimes d f .
$$

Prove by a spectral sequence argument that

$$
H_{D}(E \otimes F)=H_{d}(E) \otimes H_{d}(F) .
$$

## Product Structures

In this section we define product structures on the Cech-de Rham complex $C^{*}\left(\mu, \Omega^{*}\right)$, the de Rham cohomology, and the Cech cohomology, and show that the isomorphism between de Rham and Cech is an isomorphism of graded algebras. We also discuss the product structures on a spectral sequence.

Let $Z$ be the closed forms and $B$ the exact forms on a manifold $M$. From the antiderivation property of the exterior derivative

$$
d(\omega \cdot \eta)=(d \omega) \cdot \eta+(-1)^{\operatorname{deg} \omega} \omega \cdot d \eta
$$

it follows that $Z$ is a subring of $\Omega^{*}(M)$ and $B$ is an ideal in $Z$. Hence the wedge product makes the de Rham cohomology $H_{D R}^{*}(M)=Z / B$ into a graded algebra

On the double complex $C^{*}\left(\mathfrak{U}, \Omega^{*}\right)$, where $\mathfrak{H}$ is any open cover of $M$, a natural product

$$
\cup: C^{p}\left(\mathfrak{U}, \Omega^{q}\right) \otimes C^{r}\left(\mathfrak{U}, \Omega^{s}\right) \rightarrow C^{p+r}\left(\mathcal{U}, \Omega^{q+s}\right)
$$

can be defined as follows. If $\omega$ is in $C^{p}\left(u, \Omega^{q}\right)$ and $\eta$ is in $C^{r}\left(\mu, \Omega^{s}\right)$, then

$$
\begin{equation*}
(\omega \cup \eta)\left(U_{a 0 \ldots a_{p}+}\right)=(-1)^{a r} \omega\left(U_{a 0} \ldots a_{p}\right) \cdot \eta\left(U_{a_{p} \ldots a_{p}+r}\right), \tag{14.24}
\end{equation*}
$$

where on the right-hand side both forms are understood to be restricted to $U_{a_{0} \ldots a_{p+1}}$.

Remark 14.25. The sign $(-1)^{\text {qr }}$ is needed to make the differential operator $D$ into an antiderivation relative to the product structure. It makes sense that this should be the sign, for in defining the product, $p$ and $r$ are brought together, and so are $q$ and $s$, so the order of $q$ and $r$ in $C^{p}\left(\left\lfloor, \Omega^{q}\right) \otimes C^{r}(山\right.$, $\boldsymbol{\Omega}^{\mathbf{3}}$ ) are interchanged. It is a useful principle that whenever two symbols of degrees $m$ and $n$ are interchanged in a graded algebra, there should be the $\operatorname{sign}(-1)^{m n}$.

Exercise 14.26. Let $\omega \in K^{p, q}$ and $\eta \in K^{r, s}$. Show that

1) $\delta(\omega \cup \eta)=(\delta \omega) \cup \eta+(-1)^{\operatorname{deg} \omega} \omega \cup . \delta \eta$
2) $D^{\prime \prime}(\omega \cup \eta)=\left(D^{\prime \prime} \omega\right) \cup \eta+(-1)^{\text {des } \omega} \omega \cup D^{\prime \prime} \eta$
3) $D(\omega \cup \eta)=(D \omega) \cup \eta+(-1)^{\operatorname{deg} \omega} \omega \cup D^{\prime \prime} \eta$, where $\operatorname{deg} \omega=p+q$.

We will often write $\omega \cdot \eta$ or even $\omega \eta$ for $\omega \cup \eta$.
The inclusion of the Cech complex $C^{*}(\mathfrak{U}, \mathbb{R})$ in the Cech-de Rham complex induces a product structure on $C^{*}(\mu, \mathbb{R})$ : if $\omega$ is a $p$-cochain and $\eta$ an $r$-cochain, then

$$
\begin{equation*}
(\omega \cdot \eta)_{\alpha_{0} \ldots a_{p}+p}=\omega_{a_{0} \ldots \alpha_{p}} \cdot \eta_{\alpha_{p} \ldots a_{p+r}} \tag{14.27}
\end{equation*}
$$

By Exercise 14.26, $\delta$ is an antiderivation relative to this product. So just as in the case of de Rham cohomology this makes the Cech cohomology $H^{*}(\mathfrak{U}, \mathbb{R})$ into a graded algebra. If $\mathfrak{B}$ is a refinement of $\mathfrak{U}$, then the restriction map $H^{*}(\mathfrak{U}, \mathbb{R}) \rightarrow H^{*}(\mathfrak{B}, \mathbb{R})$ is a homomorphism of algebras. Hence the direct limit $H^{*}(M, \mathbb{R})$ is also a graded algebra. Note that (14.27) also makes sense for the Cech complex $C^{*}(\mathfrak{U}, \mathbb{R})$ on a topological space $X$; this gives a product structure on the Cech cohomology $H^{*}(X, \mathbb{R})$ of any topological space $X$.

With the product structures just defined, both inclusions

$$
r: \Omega^{*}(M) \rightarrow C^{*}\left(\mathfrak{U}, \Omega^{*}\right)
$$

and

$$
i: C^{*}(\mathfrak{U}, \mathbf{R}) \rightarrow C^{*}\left(\mathfrak{U}, \Omega^{*}\right)
$$

are algebra homoriorphisms. Since as we saw in Proposition 8.8, for good cover these homomorphisms induce bijective maps in cohomology

$$
\begin{aligned}
H_{D R}^{*}(M) & \simeq H_{D}\left\{C^{*}\left(\mathfrak{U}, \Omega^{*}\right)\right\} \\
H^{*}(\mathfrak{U}, \mathbb{R}) & \simeq H_{D}\left\{C^{*}\left(\mathfrak{U}, \Omega^{*}\right)\right\},
\end{aligned}
$$

the isomorphism between $H_{D R}^{*}(M)$ and $H^{*}(\mathfrak{U}, \mathbb{R})$ is an algebra isomorphism. Because $H^{*}(M, \mathbb{R})=H^{*}(\mathbb{U}, \mathbb{R})$ for a good cover $\mathfrak{U}$, we have the following.

Theorem 14.28. The isomorphism between de Rham and Cech

$$
H_{D R}(M) \simeq H^{*}(M, \mathbb{R})
$$

is an isomorphism of graded algebras.
If a double complex $K$ has a product structure relative to which its differential $D$ is an antiderivation, the same is true of all the groups $E$, and their operators $d_{r}$, since $E_{r}$ is the homology of $E_{r-1}$ and $d_{r}$ is induced from D. With product structures, Theorem 14.14, becomes

Theorem 14.29 Let $K$ be a double complex with a product structure relative to which $D$ is an antiderivation. There exists a spectral sequence

$$
\left\{E_{r}, d_{r}: E_{r}^{p, 4} \rightarrow E_{p}^{p+r_{1}-r+1}\right\}
$$

converging to $H_{D}(K)$ with the following properties:

2) Each $E_{r}$, being the homology of its predecessor $E_{r-1}$, inherits a product structure from $E_{r-1}$. Relative to this product, $d_{r}$ is an antiderivation.

Warning. Although both $E_{\infty}$ and $H_{D}(K)$ inherit their ring structures from $K$, they are generally not isomorphic as rings.

Exercise 14.30 The product structure on the tensor product $A \otimes B$ of two graded rings $A$ and $B$ is given by

$$
(a \otimes b)(c \otimes d)=(-1)^{(\cos b) \times(d o s c)}(a c \otimes b d), \quad a, c \in A, \quad b, d \in B .
$$

Show that if $\pi: E \rightarrow M$ is a fiber bundle with fiber $F$ over a simply connected manifold $M$, then the isomorphism of the $E_{2}$ term of the spectral sequence with $H^{*}(M) \otimes H^{*}(F)$ is an isomorphism of graded algebras.

Remark 14.31. Thus in Leray's theorem (Theorem 14.18) each group $E_{r}$ is an algebra relative to which $d_{r}$ is an antiderivation; furthermore, if $M$ is simply connected, $E_{2}$ is isomorphic to $H^{*}(M) \otimes H^{*}(F)$ as a graded algebra.

Example 14.32 (The ring structure of $H^{*}\left(\right.$ CP $\left.^{\text {a }}\right)$ ). Assume for now that $n=2$ In example 14.22, by applying the spectral sequence of the fiber bundle

$$
S^{1} \rightarrow S^{5}=\begin{aligned}
& \\
& \\
& \\
& C P^{2}
\end{aligned}
$$

we computed the additive structure of the graded algebra $H^{*}\left(C P^{2}\right)$. We found that the $E_{2}$ term is

The two $d_{2}$ 's shown are isomorphisms. Let $a$ be a generator of

$$
E_{2}^{0.1} \simeq H^{0}\left(\mathbb{C} P^{1}\right) \otimes H^{1}\left(S^{1}\right) \simeq H^{1}\left(S^{1}\right)
$$

Then $d_{2} a=x$ is a generator of

$$
E_{2}^{2,0} \simeq H^{2}\left(C P^{1}\right) \otimes H^{0}\left(S^{1}\right) \simeq H^{2}\left(C P^{1}\right)
$$

and $x \cdot a$ is a generator of

$$
E_{2}^{2.1}=H^{2}\left(C P^{1}\right) \otimes H^{1}\left(S^{1}\right) .
$$

Because $d_{2}: E_{2}^{2,1} \rightarrow E_{2}^{4,0}$ is an isomorphism, a generator of $E_{2}^{4,0}=$ $H^{4}\left(\mathbb{C} P^{2}\right)$ is

$$
d_{2}(x \cdot a)=x \cdot d_{2} a=x^{2} .
$$

So as a ring,

$$
H^{*}\left(C P^{2}\right)=R[x] /\left(x^{3}\right)
$$

In general, the same argument yields the ring structure of CP ${ }^{\text {a }}$ as

$$
H^{*}\left(C P^{n}\right)=\mathbf{R}[x] /\left(x^{n+1}\right)
$$

where $x$ is an element in dimension 2.

## The Gysin Sequence

The spectral sequence of a fiber bundle is essentially a way of describing the complicated algebraic relations among the cohomology of the basc space, the fiber, and the total space of the bundle. In certain special situations the spectral sequence simplifies to a long exact sequence. One such special case is the cohomology of a sphere bundle. The resulting sequence is called the Gysin sequence, which we now derive.

Let $\pi: E \rightarrow M$ be an oriented sphere bundle with fiber $S^{k}$. By the orientability assumption, for any good cover $H$ on $M$, the locally constant presheaf $\mathscr{H}^{q}$ has no monodromy and is the constant presheaf $R$. Therefore the $E_{2}$ term of the spectral sequence is
$E \sum_{2}^{p}=H^{P}(M) \otimes H^{4}\left(S^{\prime}\right)$.

Let $n$ be any nonnegative integer. Since nothing in $E_{2}^{n-k, k}$ can get killed (that is, nothing there lies in the image of 4, for $r \geq 2$ ), $E_{\infty}^{n-k, k}$ is the sub-
group of $E_{2}^{n-k, k}$ consisting of those elements with $d_{3}=d_{4}=\cdots=0$. Hence there is an inclusion

$$
0 \rightarrow E_{\infty}^{n-k, k} \rightarrow E_{2}^{n-k, k} .
$$

This can be extended to an exact sequence

$$
\begin{gather*}
0 \rightarrow E_{\infty}^{n-k, k} \rightarrow E_{2}^{n-k, k} \xrightarrow{4} E_{2}^{n+1,0} \rightarrow E_{\infty}^{n+1,0} \rightarrow 0  \tag{*}\\
\| \\
H^{n-k}(M) H^{n+1}(M)
\end{gather*}
$$

where the last map, called an edge homomorphism, exists and is surjective because every element of $E_{2}^{n+1.0}$ survives to $E_{\infty}$.

Because of the shape of the $E_{2}$ term, the filtration (14.13) on $H^{n}(E)$ becomes

$$
H^{n}(\underbrace{E) \supset E_{\infty}^{n, 0}}_{E_{\infty}^{-k-k, k}} \supset 0
$$

in other words, there is an exact sequence

$$
\begin{equation*}
0 \rightarrow E_{\infty}^{n .0} \rightarrow H^{n}(E) \rightarrow E_{\infty}^{n-k, k} \rightarrow 0 . \tag{}
\end{equation*}
$$

The two sequmses (*) and (**) may be combined into a single long exact sequence

$$
\cdots \rightarrow H^{n}(E) \xrightarrow{\bullet} H^{n-k}(M) \xrightarrow{4} H^{n+1}(M) \xrightarrow{\Leftrightarrow} H^{n+1}(E) \rightarrow \cdots .
$$

This is the Gysin sequence of the sphere bundle.
It remains to identify the maps in the Gysin sequence. Let $\mathfrak{U}$ be a good cover on $M$. The map $\alpha$ is the composition of

$$
\begin{aligned}
H^{n}(E) \xrightarrow{\text { projootion }} E_{\infty}^{n-k, k} \subset E_{2}^{n-k, k} & =H^{n-k}\left(\pi^{-1} \mathcal{U}_{,} \mathscr{X}^{k}\right) \\
& =H^{n-k}(M) \otimes H^{k}\left(S^{k}\right) \simeq H^{n-k}(M)
\end{aligned}
$$

In this sequence of maps the first three are the identity on the level of forms and the last one sends a generator of $H^{k}\left(S^{k}\right)$ to 1 by integration. Therefore $\alpha$ is integration along the fiber.

Next consider $d_{k}$. Representing an element of

$$
E_{2}^{n-k, k}=H^{u-k}(M) \otimes H^{k}\left(S^{k}\right)
$$

by $\left(\pi^{*} \omega\right) \cdot(-p)$ where $\omega$ is a closed form on $M$ and $\psi$ is the angular form on $E$, we see that

$$
\begin{aligned}
d_{k}\left(\left(\pi^{*} \omega\right)(-\psi)\right) & =d_{k}\left(\left(\pi^{*} \omega\right)(-\psi)\right)=(-1)^{n-k}\left(\pi^{*} \omega\right) d_{k}(-\psi) \\
& =(-1)^{\pi^{-k}\left(\pi^{*} \omega\right)\left(\pi^{*} e\right) .}
\end{aligned}
$$

Hence, up to a sign $d_{k}: H^{n-k}(M) \rightarrow H^{n+1}(M)$ is multiplication by the Euler class $e$.

Finally the map $\beta$ is the composition

$$
\begin{aligned}
H^{n+1}(M) & =H^{n+1}\left(\mathfrak{u}, \mathscr{H}^{0}(F)\right) \stackrel{x^{*}}{\rightrightarrows} H^{n+1}\left(\pi^{-1} \mathfrak{U}, \mathscr{H}^{0}(F)\right) \\
& =E_{2}^{n+1.0} \xrightarrow{\text { projection }} E_{\infty}^{n+1,0} \subset H^{n+1}(E) .
\end{aligned}
$$

So $\beta: H^{n+1}(M) \rightarrow H^{n+1}(E)$ is the natural pullback map $\pi^{*}$.
We summarize this discussion as follows.
Proposition 14.33. Let $\pi: E \rightarrow M$ be an oriented sphere bundle with fiber $S^{*}$. Then there is a long exact sequence

$$
\cdots \rightarrow H^{m}(E) \xrightarrow{x_{0}} H^{n-k}(M) \xrightarrow{\hat{*}} H^{n+1}(M) \xrightarrow{\boldsymbol{s}^{*}} H^{n+1}(E) \rightarrow \cdots,
$$

in which the maps $\pi_{*}, \wedge e$, and $\pi^{*}$ are integration along the fiber, multiplication by the Euler class, and the natural pullback, respectively.

Exercise 14.33.1. Show that if the sphere bundle comes from a vector bundle $\pi: V \rightarrow M$, then the long exact sequence in the proposition may be identified with the relative exact sequence of the inclusion $i: V^{0} \rightarrow V$, where $V^{0}$ is the complement of the zero section in $V$. (Compare with Proposition 6.49.)

## Leray's Construction

We consider now more generally not a fiber bundle but any map $\pi: X \rightarrow Y$ from one manifold to another, and study how the cohomology groups of $X$ relate to those of $Y$. Let $\mathcal{U}$ be any cover for $Y$, not necessarily a good cover. Then $\pi^{-1} \mathfrak{u}$ is a cover for $\boldsymbol{X}$. By the Mayer-Vietoris principle (Proposition 8.8 or 14.16)

$$
H^{*}(X)=H_{D}\left\{C^{*}\left(\pi^{-\frac{1}{2}} \mathfrak{U}, \Omega^{*}\right)\right\} .
$$

By Theorem 14.14, if $K$ is the double complex $C^{*}\left(\pi^{-1} \mathfrak{u}, \Omega^{*}\right)$ on $X$, then the spectral sequence of $K$ has

$$
E_{\infty}=H_{D}\left\{C^{*}\left(\pi^{-1} \mathfrak{U}, \Omega^{*}\right)\right\}
$$

and

$$
E_{\xi}^{\cdot}{ }^{4}=H_{\delta} \cdot{ }^{4} H_{a}\left\{C^{*}\left(\pi^{-1} u, \Omega^{*}\right)\right\} .
$$

Here

$$
H_{d}^{p, q}(K)=\prod_{a 00<\ldots<\alpha_{p}} H^{q}\left(\pi^{-1} U_{\alpha 0} \ldots \alpha_{p}\right)=C^{p}\left(\mathbb{X}, \mathscr{H}^{p}\right)
$$

where $\mathscr{H}^{q}$ is the presheaf on $Y$ defined by $\mathscr{H}^{q}(U)=H^{q}\left(\pi^{-1} U\right)$. In summary, there is a spectral sequence converging to $H^{*}(X)$ with $E_{2}$ term

$$
E_{i}^{p^{\prime}}=H^{P}\left(u, x^{\emptyset}\right) .
$$

The main difference between this situation and that of a fiber bundle (Theorem 14.18) is that the presheaf $\mathscr{H}^{q}$ is no longer locally constant on $\mathfrak{U}$; indeed the groups $H^{9}\left(\pi^{-i} U\right)$ will in general be different for different contractible open sets $U$.

Example 14.34. Consider the vertical projection of a circle $S^{1}$ onto a segment $I$. Cover $I$ with three open sets $U_{0}, U_{1}, U_{2}$ as shown in Figure 14.1.

Figure 14.1

The presheaf $\mathscr{H}^{0}$ attaches a group to each vertex and each edge of the nerve $N(\mathfrak{U})$ in the way indicated below

$H_{d}$ of the double complex $C^{*}\left(\pi^{-1} \mathfrak{u}, \Omega^{*}\right)$ is

with $\delta$ given by $\left(b,\left(c_{1}, c_{2}\right), d\right) \rightarrow\left(\left(c_{1}-b, c_{2}-b\right)\left(d-c_{1}, d-c_{2}\right)\right)$, Thus ker $\delta=\{(b,(b, b), b)\}$ and $H_{\delta}^{0 \cdot}{ }^{0} H_{d}=\boldsymbol{R}$. Since im $\delta$ is 3-dimensional, $H_{\delta}^{1,0} H_{d}=\mathbb{R}$. So $H_{\delta} H_{d}$ is

In this case, then, $E_{2}=E_{\infty}$ and we get the cohomology of $S^{1}$.
Let us find a nontrivial 1-cochain in $C^{1}\left(\mathfrak{l}, \mathscr{K}^{\circ}\right)$ that represents a generator of $H^{1}\left(S^{1}\right)$. A 1 -cochain in $C^{1}\left(\mu, \mathscr{H}^{0}\right)$ is given by a 4 tuple $((r, s),(t, u)$ ). Such a 4 -tuple is exact if and only if $r-s=u-t$. Therefore as a generator of $H^{1}\left(S^{1}\right)$ we may take $\left.(1,0),(0,0)\right)$, i.e., the 1 -cochain $\tau$ (see Figure 14.2)

Figure 14.2
such that

$$
\begin{aligned}
& \tau\left(U_{0 \Omega}\right)=(1,0) \\
& \tau\left(U_{12}\right)=(0,0) .
\end{aligned}
$$

Exercise 14.35. Project the sphere $S^{\mathbf{2}}$ to a disc $D$ (Figure 14.3) and compute $H^{*}\left(S^{2}\right)$ by Leray's method.

Figure 14.3
Exercise 14.36. Let $Y$ be a manifold and $\mathfrak{U}$ a good cover of $Y$. Denote by $\beta_{p}$ the number of nonempty $(p+1)$-fold intersections $U_{a_{0} \ldots, j}$. Show that $\chi(Y)=\Sigma(-1)^{p} \beta_{p}$.
Exercise 14.37. Let $\pi: X \rightarrow Y$ be any map and $\mathfrak{U}$ a good cover of $Y$. Show that

$$
X(X)=\sum_{p, q} \sum_{\alpha_{0}<\cdots<a_{p}}(-1)^{p+q} \operatorname{dim} H^{q}\left(\pi^{-1} U_{a_{0}} \ldots \alpha_{p}\right)
$$

Deduce that if $\pi: X \rightarrow Y$ is a fiber bundle with fiber $F$, then

$$
x(X)=x(F) x(n) .
$$

## §15 Cohomology with Integer Coefficients

An element in a $\mathbf{Z}$-module is said to be torsion if some integral multiple of it is zero. Since the de Rham theory is a cohomology theory with real coefficients, it necessarily overlooks the torsion phenomena. For applications to homotopy theory, however, it is essential to investigate the torsion. The goal of this section is to replace the differential form functor $\Omega^{*}$ with the singular cochain functor $S^{*}$, define the singular cohomology, and show that the preceding results on spectral sequences carry over to integer coefficients. The key as before is the Mayer-Vietoris sequence for countably many open sets. The natural setting for the singular theory is the category
of topological spaces and continuous maps, rather than the more restrictive category of differentiable manifolds and $C^{\infty}$ maps of de Rham theory. Unless otherwise indicated, from here till the end of Section 18 we will work in the continuous category. We begin with a review of the basic definitions of singular homology.

## Singular Homology

Via the map

$$
\left(x_{1}, \ldots, x_{n}\right) \mapsto\left(x_{1}, \ldots, x_{n}, 0\right)
$$

each Euclidean space $\mathbb{R}^{n}$ is naturally included in $\mathbb{R}^{n+1}$. Viewing each $\boldsymbol{R}^{n}$ as a subspace of $\mathbf{R}^{n+1}$ in this way we consider the union

$$
\boldsymbol{R}^{\infty}=\bigcup_{n \geq 0} \boldsymbol{R}^{n}
$$

Denote by $P_{i}$ the $i$-th standard basis vector in $R^{\infty}$; it is the vector whose $i$-th component is 1 and whose other components are all 0 . Let $P_{0}$ be the origin. We define the standard $q$-simplex $\Delta_{q}$ to be the set

$$
\Delta_{q}=\left\{\sum_{j=0}^{q} t_{j} P_{j} \mid \sum_{j=0}^{q} t_{j}=1\right\}
$$

If $X$ is a topological space, a singular $q$-simplex in $X$ is a continuous map $s: \Delta_{q} \rightarrow X$ and a singular $q$-chain in $X$ is a finite linear combination with integer coefficients of singular $q$-simplices. Collectively these $q$-chains form an Abelian group $S_{\ell}(X)$. We define the $i$-th face map of the standard $q$ simplex to be the function

$$
\partial_{q}^{d}: \Delta_{q-1} \rightarrow \Delta_{q}
$$

given by (see Figure 15.1)

$$
\partial_{d}\left(\sum_{j=0}^{1-1} t_{j} P_{j}\right)=\sum_{j=0}^{1-1} t_{j} P_{j}+\sum_{j=1+1}^{4} t_{j} P_{j}
$$

Figére 15.1

The graded group of singular chains,

$$
S_{*}(X)=\bigoplus_{q \geq 0} S_{q}(X)
$$

can be made into a differential complex with boundary operator

$$
\begin{aligned}
& \partial: S_{q}(X) \rightarrow S_{q-1}(X) \\
& \partial s=\sum_{i=0}^{q}(-1)^{i} s \circ \partial_{q}^{t}
\end{aligned}
$$

It is easily checked that $\partial^{2}=0$. The homology of this complex is the singular homology with integer coefficients of $X$, denoted $H_{\psi}(X)$ or $H_{*}(X ; \mathbb{Z})$. By taking the linear combination of simplices to be with coefficients in an Abelian group G, we obtain similarly singular homology with coefficients in $G, H_{\xi}(X ; G)$.

The degree of a 0 -chain $\sum n_{i} P_{i}$ is by definition $\sum n_{i}$. Suppose $X$ is path connected. If $-P$ and $Q$ are in a 0 -chain on $X$, then any path from $P$ to $Q$ is a 1 -simplex with boundary $Q-P$. Hence a 0 -chain on a path-connected space is the boundary of a 1 -chain if and only if it has degree 0 . This gives rise to a short exact sequence

$$
0 \rightarrow \partial S_{1}(X) \rightarrow S_{0}(X) \xrightarrow{\text { deg }} \mathbb{Z} \rightarrow 0
$$

from which it follows that if $X$ is path connected, $H_{0}(X)=\mathbb{Z}$. In general,

$$
\operatorname{dim} H_{0}(X)=\text { the number of path components of } X .
$$

## The Cone Construction

The goal of this section is to compute the singular homology of $\mathbb{R}^{R}$. If $s$ in $S_{q}\left(\mathbb{R}^{n}\right)$ is a $q$-simplex in $\mathbb{R}^{n}$, we define the cone over $s$ to be the $(q+1)$ simplex $K s$ in $S_{q+1}\left(R^{\prime \prime}\right)$ given by

$$
K s\left(\sum_{j=0}^{q+1} t_{j} P_{j}\right)=\left(1-t_{q+1}\right) s\left(\sum_{j=0}^{q} \frac{t_{j}}{1-t_{q+1}} P_{i}\right)
$$

This is the cone in $\mathbb{R}^{n}$ with vertex the origin and base the simplex $s$. To make sense of the formula, we view the last coordinate $t_{q+1}$ as "time"; as time goes from 0 to 1 , the cone $K \dot{s}$ moves from $s$ to the origin. For the singular simplex $s$ pictured in Figure 15.2, the cone $K s$ is the "tetrahedron" and

$$
\begin{aligned}
& \partial K s=0 \text { th face }-1 \text { st face }+2 \text { nd face }-s \\
& K \partial s=0 \text { th face }-1 \text { ist face }+2 \text { nd face } .
\end{aligned}
$$

Figure 15.2
In general we have the following.
Proposition 15.1. Let $K: S_{*}\left(\mathbb{R}^{n}\right) \rightarrow S_{*+1}\left(\mathbb{R}^{n}\right)$ be the cone construction. Then

$$
\partial K-K \partial=(-1)^{9+1}
$$

on $S_{q}\left(\mathbb{R}^{n}\right)$ for $q \geq 1$.
Proof. The geometrical idea is clear from Figure 15.2. The proof itself is a routine matter of unravelling the definitions. We leave it to the reader.

In other words, the cone construction $K$ is a homotopy operator between the identity map and the zero map on $S_{q}\left(\mathbb{R}^{n}\right), q \geq 1$. Consequently,

$$
H_{q}\left(\mathbb{R}^{n}\right)= \begin{cases}0 & q \geq 1 \\ \mathbb{Z} & q=0\end{cases}
$$

The Mayer-Vietoris Sequence for Singular Chains
Let $\mathbb{U}=\left\{U_{a}\right\}_{a \in J}$ be an open cover of the topological space $X$. Just as for differential forms on a manifold, the sequence of inclusions

$$
X \leftarrow \coprod_{\alpha_{0}} U_{\alpha_{0}} \coprod_{\xi_{0}<a_{1}} \leftleftarrows U_{\alpha_{0} a_{1}} \leftleftarrows \ldots
$$

induces a Mayer-Vietoris sequence. However, for technical reasons which will become apparent in the proof of Proposition 15.2 (to show the surjectivity at one end of the Mayer-Vietoris sequence), we must consider here the group $S_{*}^{u}(X)$ of $\mathbb{U}$-small chains in $X$; these are chains made up of simplices
each of which lies in some open set of the cover $\mathbb{U}$. The inclusion

$$
i: S_{*}^{\mathrm{u}}(X) \rightarrow S_{*}(X)
$$

is clearly a chain map, i.e., it commutes with the boundary operator $\partial$. Indeed, it is a chain equivalence. The proof of this fact is tedious and we will omit it (Vick [1, Appendix I, p. 207]), but the idea behind it is quite intuitive: to get an inverse chain map, subdivide each chain in $X$ until it becomes $\mathcal{U}$-small. In any case the upshot is that to compute the singular cohomology of $X$ it suffices to use $\mathfrak{U}$-small chains: $H\left(S_{*}(X)\right)=H\left(S_{*}^{4}(X)\right)$.

Define the Cech boundary operator

$$
\delta: \underset{a_{0}<\cdots<a_{p}}{\bigoplus} S_{q}\left(U_{a_{0} \cdots a_{p}}\right) \rightarrow \bigoplus_{a_{0}<\cdots<a_{p-1}} S_{q}\left(U_{a_{0} \cdots a_{p-1}}\right)
$$

by the "alternating sum formula"

$$
(\delta c)_{\alpha_{0} \cdots \alpha_{p-1}}=\sum_{a} c_{\alpha \alpha_{0} \cdots \alpha_{p-1}}
$$

Here, as always, we adopt the convention that interchanging two indices in $c_{a_{0} \ldots \alpha_{p}}$ introduces a minus sign. The fact that $\delta^{2}=0$ is proved as in Proposition 12.12. The boundary operator $\delta$ on $\bigoplus S_{q}\left(U_{\alpha 0}\right) \rightarrow S_{q}(X)$ is simply the sum; we denote this by $\varepsilon$.

Proposition 15.2 (The Mayer-Vietoris Sequence for Singular Chains). The following sequence is exact

$$
0 \leftarrow S_{q}^{\mathfrak{u}}(X) \leftarrow \bigoplus_{a_{0}} S_{q}\left(U_{\alpha_{0}}\right) \stackrel{\delta}{\oplus} \underset{a_{0}<\alpha_{1}}{\bigoplus} S_{q}\left(U_{\alpha_{0} \alpha_{1}}\right) \stackrel{\triangleright}{\leftarrow}
$$

Although this sequence bears a formal resemblance to the generalized Mayer-Vietoris sequence for compact supports (Proposition 12.12), because we do not have partitions of unity at our disposal now, the second half of the proof of (12.12) does not apply.

Lemma 15.3. Let

$$
0 \rightarrow A \rightarrow B \rightarrow C \rightarrow 0
$$

be a short exact sequence of differential complexes. If two out of the three complexes have zero homology, so does the third.

Proof. Consider the long exact sequence in homology

$$
\cdots \rightarrow H_{q}(A) \rightarrow H_{q}(B) \rightarrow H_{q}(C) \rightarrow H_{q-1}(A) \rightarrow \cdots
$$

Proof of Proposition 15.2. For two open sets the Mayer-Vietoris sequence is

$$
\begin{aligned}
0 \leftarrow S_{q}^{u}\left(U_{0} \cup U_{1}\right) & \leftarrow S_{q}\left(U_{0}\right) \oplus S_{q}\left(U_{1}\right) \leftarrow S_{\&}\left(U_{01}\right) \leftarrow 0 \\
\left(c_{10}, c_{01}\right) & \longmapsto c_{01}
\end{aligned}
$$

The exactness of this sequence follows directly from the definition. For three open sets the sequence is

$$
\begin{aligned}
& 0 \sim S_{1}^{2}\left(U_{0} \cup U_{1} \cup U_{2}\right)-S_{\alpha}\left(U_{0}\right) \oplus S_{\alpha}\left(U_{1}\right) \oplus S_{\alpha}\left(U_{2}\right) \backsim S_{\alpha}\left(U_{01}\right) \oplus S_{\alpha}\left(U_{02}\right) \oplus S_{\alpha}\left(U_{12}\right)-S_{\alpha}\left(U_{012}\right) \sim 0 \\
& \left(c_{10}+c_{20}, c_{01}+c_{21}, c_{02}+c_{12}\right) \longrightarrow\left(c_{01}, c_{02}, c_{12}\right) \\
& \left(c_{201}, c_{102}, c_{012}\right) \longrightarrow c_{012}
\end{aligned}
$$

The Mayer-Vietoris sequence for two open sets injects into the one for three open sets, giving rise to the following commutative diagram with exact columns

The $\cdot \mathbb{U}$ in $S^{\mathfrak{n}}\left(U_{0} \cup U_{1}\right)$ is the open cover $\left\{U_{0}, U_{1}\right\}$, while the $\tilde{U}$ in $S^{\mathscr{m}}\left(U_{0} \cup\right.$ $U_{1} \cup U_{2}$ ) is the open cover $\left\{U_{0}, U_{1}, U_{2}\right\}$. So the group

$$
S^{\mathrm{a}}\left(U_{0} \cup U_{1} \cup \bar{U}_{2}\right) / S^{\underline{\mathrm{a}}}\left(U_{0} \cup U_{1}\right)
$$

is generated by the simplices in $U_{2}$ which do not lie entirely in $U_{0}$ or $U_{1}$ (see Figure 15.3).

Figure 15.3

We now prove the exactness of the rows of the commutative diagram. The bottom row is almost the Mayer-Vietoris sequence for the open cover $\left\{U_{02}, U_{12}\right\}$; it is exact except possibly at $S\left(U_{2}\right)$. Clearly $\beta \circ \delta=0$. Now if $c$ is in $S\left(U_{2}\right)$ and $\beta(c)=0$, then $c$ is a chain in $U_{2}$ whose simplices lie either in $U_{0}$ or in $U_{1}$, i.e., $c$ is in the image of $S\left(U_{02}\right) \oplus S\left(U_{12}\right)$. Therefore the bottom row is exact. Note that each row of the commutative diagram is a differential complex and the commutative diagram may be regarded as a short exact sequence of differential complexes. Since the top and bottom complexes have zero cohomology, by Lemma 15.3 so does the middle one; in other words, the middle row is exact. This proves the exactness of the Mayer-Vietoris sequence for a cover consisting of three open sets. In general the Mayer-Vietoris sequence for $r$ open sets injects into the one for $r+1$ open sets. By the above technique and induction, one proves the Mayer-Vietoris sequence for any finite cover.

Now consider a countable cover $\mathfrak{U}=\left\{U_{\alpha}\right\}$. By the definition of the direct sum, an element $c$ of $\oplus S\left(U_{\alpha_{0} \ldots \alpha_{p}}\right)$ has only finitely many nonzero components. These components can involve only finitely many open sets. Therefore if $\delta c=0$, by the Mayer-Vietoris sequence for a finite cover, we know that $c=\delta b$ for some $b$ in $\oplus S\left(U_{a_{0} \ldots a_{p+1}}\right)$. This proves the exactness of the Mayer-Vietoris sequence for countably many open sets.

Remark 15.4. If the coefficients are in an arbitrary Abelian group $G$, the same proof holds word for word.

Now suppose the open cover $\mathfrak{U}$ consists of two open sets $U$ and $V$. By Proposition 15.2, there is a short exact sequence of singular chains

$$
\begin{equation*}
0 \rightarrow S_{q}(U \cap V) \rightarrow S_{q}(U) \oplus S_{q}(V) \rightarrow S_{q}^{u}(X) \rightarrow 0 \tag{15.5}
\end{equation*}
$$

The associated long exact sequence in homology is the usual homology Mayer-Vietoris sequence.

Corollary 15.6 (The Homology Mayer-Vietoris Sequence for Two Open Sets). Let $X=U \cup V$ be the union of two open sets. Then there is a long exact sequence in homology

$$
\cdots \rightarrow H_{q}(U \cap V) \stackrel{f}{\rightarrow} H_{q}(U) \oplus H_{q}(V) \stackrel{g}{\rightarrow} H_{q}(X) \rightarrow H_{q-1}(U \cap V) \rightarrow \cdots
$$

Here $f$ is the map induced by the signed inclusion $a \mapsto(-a, a)$ and $g$ is the sum $(a, b) \mapsto a+b$.

## Singular Cohomology

A singular $q$-cochain on a topological space $X$ is a linear functional on the $\mathbb{Z}$-module $S_{q}(X)$ of singular $q$-chains. Thus the group of singular $q$-cochains is $S^{q}(X)=\operatorname{Hom}\left(S_{q}(X), \mathbb{Z}\right)$. With the coboundary operator $d$ defined by
$(d \omega)(c)=\omega(\partial c)$, the graded group of singular cochains $S^{*}(X)=\bigoplus S^{\top}(X)$ becomes a differential complex; the homology of this complex is the singular cohomology of $X$ with integer coefficients. Replacing $\mathbb{Z}$ with an Abelian group $G$ we obtain the singular cohomology with coefficients in $G$, denote $H^{*}(X ; G)$. For the rest of this chapter we will reserve $H^{*}(X)$ for the singular cohomology with integer coefficients and write $H_{D_{R}}^{*}(X)$ for the de Rham cohomology.

A function $\omega$ on $X$ is a 0 -cocycle if and only if $\omega(\partial c)=0$ for all paths $c$ in $X$. It follows that such an $\omega$ is constant on each path component of $\boldsymbol{X}$. Therefore, $H^{0}(X)=S^{0}(X)=\mathbb{Z} \oplus \mathbb{Z} \oplus \cdots \oplus \mathbb{Z}$ where there are as many copies of $\mathbb{Z}$ as there are path components of $X$.

REMARK The singular cohomology does not always agree with the Cech cohomology. For instance,

$$
\operatorname{dim} H_{\mathrm{sing}}^{0}(X)=\# \text { path components of } X
$$

but

$$
\operatorname{dim} H_{\text {Cech }}^{0}(X)=\# \text { connected components of } X
$$

We now compute the singular cohomology of $\mathbb{R}^{n}$. Define the operator $L: S^{q}\left(\mathbb{R}^{n}\right) \rightarrow S^{\varphi-1}\left(\mathbb{R}^{n}\right)$ to be the adjoint of the cone construction $K:$ if $\sigma \in$ $S^{q}\left(\mathbb{R}^{\prime \prime}\right)$ and $c \in S_{q-1}\left(\mathbb{R}^{n}\right)$,

$$
(L \sigma)(c)=\sigma(K c)
$$

Then for $\sigma \in S^{q}\left(\mathbb{R}^{\prime \prime}\right)$ and $c \in S_{q}\left(\mathbb{R}^{\prime \prime}\right)$,

$$
\begin{aligned}
((d L-L d) \sigma) c & =(d(L \sigma)) c-(L(d \sigma))(c) \\
& =(L \sigma)(\partial c)-(d \sigma)(K c) \\
& =\sigma(K \partial c)-\sigma(\partial K c) \\
& =\sigma((K \partial-\partial K) c) \\
& =\left((-1)^{q+1} \sigma\right) c \text { by Proposition 15.1. }
\end{aligned}
$$

Hence

$$
1=(-1)^{q+1}(d L-L d) \text { on } S^{q}\left(R^{n}\right), q \geq 1
$$

i.e., $L$ is a homotopy operator between the identity map and the zero map on the $q$-cochains, $q \geq 1$. It follows that

$$
H^{q}\left(\mathbb{R}^{n}\right)= \begin{cases}\mathbb{Z}, & q=0 \\ 0, & q>0\end{cases}
$$

Applying the functor $\operatorname{Hom}(, \mathbb{Z})$ to the Mayer-Vietoris sequence for singular chains we obtain the Mayer-Vietoris sequence for singular cochains

$$
\begin{equation*}
0 \rightarrow \cdot S_{u}^{*}(X) \xrightarrow{r *} \oplus S^{*}\left(U_{x_{0}}\right) \xrightarrow{\delta_{0}^{*}} \underset{a_{0}<\alpha_{1}}{\oplus} S^{*}\left(\dot{U}_{a_{0} x_{1}}\right) \xrightarrow{\delta^{*}} \ldots \tag{15.7}
\end{equation*}
$$

Since the functor $\operatorname{Hom}(, \mathbb{Z})$ preserves the exactness of a sequence of free $\mathbb{Z}$-modules (see Exercise 14.17.3), the Mayer-Vietoris sequence for singularcochains is exact.

Exercise 15.7.1. Show that $\varepsilon^{*}$ is the restriction map and $\delta^{*}$ is the alternating difference

$$
\left(\delta^{*} \omega\right)_{a_{0} \ldots \alpha_{2+1}}=\sum_{i=0}^{p+1}(-1)^{i} \omega_{\alpha_{0} \ldots \dot{\alpha}_{1} \ldots a_{1}, 1}
$$

Once we have the Mayer-Vietoris sequence we can set up the double complex $C^{*}\left(\mathcal{U}, S^{*}\right)$. Just as in the de Rham theory the double complex $C^{*}\left(\mathbb{U}, S^{*}\right)$ computes the singular cohomology of $X$. This is because by the exactness of the Mayer-Vietoris sequence, $H_{b}$ of this complex has a single zero column

$$
\mathbf{H}_{\delta}=\left|\begin{array}{c|c} 
& \\
\uparrow & \\
S^{2}(X) & 0 \\
\uparrow & \\
S^{1}(X) & 0 \\
\uparrow & \\
S^{0}(X) & 0
\end{array}\right|
$$

so that the spectral sequence degenerates at the $E_{2}$ term and

$$
H\left\{C^{*}\left(\mathbb{U}, S^{*}\right)\right\}=H_{d} H_{\delta}=H^{*}(X)
$$

To complete the analogy we will need the existence of a good cover on the topological space $X$. This presents no problem if $X$ admits a triangulation, i.e., a homeomorphism with the support of a simplicial complex, since the open star of the triangulation is a good cover. By taking barycentric subdivisions of the triangulation we can refine its star ad infinitum. Hence just as in the case of manifolds, the good covers on a triangularizable space $X$ are cofinal in the set of all covers of $X$. We note in passing that this gives an alternative proof of the existence of a good cover on a manifold since it is known that every manifold admits a triangulation (due to Cairns and Whitney, see Whitney [2, pp. 124-135]).

If $\mathfrak{U}$ is a good cover of a topological space $X$, then $H_{d}$ of the double complex $C^{*}\left(\mathfrak{u}, S^{*}\right)$ is

$$
\begin{array}{|c|c|c|c} 
& & \\
0 & & \\
& & & 0 \\
C^{0}(\mathfrak{U}, \mathbb{Z}) & C^{1}(\mathfrak{U}, \mathbb{Z}) & C^{2}(\mathfrak{U}, \mathbb{Z}) \\
\hline
\end{array}
$$

and $H_{\delta} H_{d}=H^{*}(\mathfrak{U}, \mathbb{Z})=H\left\{C^{*}\left(\mathfrak{U}, S^{*}\right)\right\}$. So there is an isomorphism between the singular cohomology and the Cech cohomology of a good cover with coefficients in the constant presheaf $\mathbb{Z}$ :

$$
H^{*}(X) \simeq H^{*}(\mathfrak{U}, \mathbf{Z})
$$

Suppose $X$ triangularizable. Since the good covers are cofinal in the set of all covers of $X$,

$$
H^{*}(X, \mathbb{Z})=H^{*}(\mathbb{U}, \mathbf{Z})
$$

where $H^{*}(X, \mathbb{Z})$ is the Cech cohomology of $X$ with coefficients in the constant presheaf $\mathbb{Z}$. Therefore,

Theorem 15.8. The singular cohomology of a triangularizable space $X$ is isomorphic to its Cech cohomology with coefficients in the constant presheaf Z. If $\mathfrak{U}$ is a good cover of $X$, then

$$
H^{*}(X) \simeq H^{*}(X, \mathbf{Z}) \simeq H^{*}(\mathbf{Z}, \mathbf{Z})
$$

Let $\pi: E \rightarrow X$ be a fiber bundle with fiber $F$ over a triangularizable topological space $X$. Just as in Theorem 14.18 , from the double complex $C\left(\pi^{-1} u, S^{*}\right)$ on $E$ we obtain a spectral sequence converging to the singular cohomology $H^{*}(E)$ whose $E_{2}$ term is

$$
E_{2}^{p, 4}=H^{p}\left(\mathcal{U}, \mathscr{X}^{P}(F)\right)
$$

where $\mathscr{H}^{q}(F)$ is the locally constant presheaf $\mathscr{H}^{q}(U)=H^{q}\left(\pi^{-1} U\right)$. If $\mathscr{H}^{q}(F)$ happens to be the constant presheaf $\mathbf{Z} \oplus \cdots \oplus \mathbf{Z}$ on $\mathfrak{U}$, then

$$
\begin{aligned}
& E_{2}^{p \cdot q}=H^{p}(\mathbb{U}, \mathbb{Z}) \oplus \cdots \oplus H^{P}(\mathbb{Z}, \mathbf{Z})=H^{P}(X) \oplus \cdots \oplus H^{P}(X) \\
& \operatorname{dim} H^{\prime} \text { Fitarise } \quad=H^{r}(X) \otimes H^{4}(F) .
\end{aligned}
$$

The singular cohomology group $H^{*}(X ; \mathbb{Z})$ can be given a product structure as follows. If $\left(A_{0} \ldots A_{q}\right)$ is a $q$-simplex in $X$, we say that $\left(A_{0} \ldots A_{r}\right)$ is its
front $r$-face and $\left(A_{q-r} \ldots A_{q}\right)$ its back $r$-face. Let $\omega$ be a $p$-cochain and $\eta$ a $q$-cochain; by definition their cup product is given by

$$
\begin{equation*}
(\omega \cup \eta)\left(A_{0} \ldots A_{p+q}\right)=\omega\left(A_{0} \ldots A_{p}\right) \eta\left(A_{p} \ldots A_{p+q}\right) . \tag{15.9}
\end{equation*}
$$

Exercise 15.10. Show that the coboundary operator $d$ is an antiderivation relative to the cup product:

$$
d(\omega \cup \eta)=(d \omega) \cup \eta+(-1)^{\operatorname{deE} \omega} \omega \cup d \eta
$$

By arguments analogous to (15.2) and (15.7) there is also a MayerVietoris sequence for singular cochains with coefficients in a commutative ring $A$. Using the cup product (15.9) in place of the wedge product, the spectral sequence of the Cech-singular complex $C^{*}\left(\mu, S^{*}\right)$ can be given a product structure just as in (14.24). The arguments in Section 14 carry over mutatis mutandis. Hence the results on spectral sequences remain true for singular cohomology with coefficients in $A$. Note however in (14.18) and (14.30) the $E_{2}$ term of a fiber bundle $\pi: E \rightarrow M$ with fiber $F$ over a simply connected base space $M$ is the tensor product $H^{*}(M ; A) \otimes H^{*}(F ; A)$ only if the cohomology of $F$ is a free $A$-module. In summary we have the following.

Theorem 15.11 (Leray's Theorem for Singular Cohomology with Coefficients in a Commutative Ring A). Let $\pi: E \rightarrow X$ be a fiber bundle with fiber $F$ over a topological space $X$ and $\mathfrak{U}$ an open cover of $X$. Then there is a spectral sequence converging to $H^{*}(E ; A)$ with $E_{2}$ term

$$
E \mathcal{F}^{p} \cdot=H^{p}\left(\mathbb{U}, \mathscr{H}^{q}(F ; A)\right) .
$$

Each $E_{r}$ in the spectral sequence can be given a product structure relative to which the differential $d_{r}$ is an antiderivation. If $X$ is simply connected and has a good cover, then

$$
E \zeta^{\varphi} e^{Q}=H^{p}\left(X, H^{q}(F ; A)\right)
$$

If in addition $H^{*}(F ; A)$ is a finitely generated free A-module, then

$$
E_{2}=H^{*}(X ; A) \otimes H^{*}(F ; A)
$$

algebras over $A$.
Exercise 15.12 (Künneth Formula for Singular Cohomology). If $X$ is a space having a good cover, e.g., a triangularizable space, and $Y$ is any topological space, prove using the spectral sequence of the fiber bundle $\pi: X \times Y \rightarrow X$ that

$$
H^{y}(X \times Y)=\underset{p+a=n}{ } H^{p}\left(X, H^{9}(Y)\right) .
$$

We examine briefly here how some of the theorems in de Rham theory carry over to the singular theory. Both the Mayer-Vietoris argument of Section 5 and the tic-tac-toe proof of Section 9 for the Leray-Hirsch theorem go through for integer coefficients, with the singular complex $C^{*}(\mathbb{H}$, $S^{*}$ ) in place of $C^{*}\left(\mathcal{U}, \Omega^{*}\right)$. However, since there may be torsion in $H^{*}(F)$, the Künneth formula in the form $H^{*}(M \times F)=H^{*}(M) \otimes H^{*}(F)$ is not true with integer coefficients; the Mayer-Vietoris argument fails because tensoring with $H^{*}(F)$ need not preserve exactness, and the tic-tac-toe proof fails because $H^{*}(F) \otimes C^{*}\left(\mathfrak{U}, S^{*}\right)$ may not be simply a finite number of copies of $C^{*}\left(\mathcal{U}, S^{*}\right)$. These difficulties do not arise in the case of the LerayHirsch theorem, since in its hypothesis the cohomology of the fiber $H^{*}(F)$ is assumed to be a free $\mathbb{Z}$-module.

Remark 15.13. Given any Abelian group $A$, let $F$ be the free Abelian group generated by a set of generators for $A$ and let $R$ be the kernel of the natural $\operatorname{map} p: F \rightarrow A$. Then

$$
\begin{equation*}
0 \rightarrow R \xrightarrow{\prime} F \rightarrow A \rightarrow 0 \tag{15.13.1}
\end{equation*}
$$

is a short exact sequence of Abelian groups. As a subgroup of a free group, $R$ is also free (Jacobson [1, §3.6]). An exact sequence such as (15.13.1), in which $F$ and $R$ are free, is called a free resolution of $A$. Let $G$ be an Abelian group. By Exercise 14.17.4, the two sequences

$$
\begin{equation*}
0 \rightarrow \operatorname{Hom}(A, G) \rightarrow \operatorname{Hom}(F, G) \xrightarrow{\mapsto} \operatorname{Hom}(R, G) \tag{15.13.2}
\end{equation*}
$$

and

$$
\begin{equation*}
R \otimes G \xrightarrow{\mid \otimes 1} F \otimes G \longrightarrow A \otimes G \longrightarrow 0 \tag{15.13.3}
\end{equation*}
$$

are exact.

## Definition

$$
\begin{aligned}
& \operatorname{Ext}(A, G)=\operatorname{coker} i^{*}=\operatorname{Hom}(R, G) / \operatorname{im} i^{*} . \\
& \operatorname{Tor}(A, G)=\operatorname{ker} i \otimes 1 .
\end{aligned}
$$

Thus Ext and Tor measure the failure of the two exact sequences (15.13.2) and (15.13.3) to be short exact. It is not hard to show that the definition of Ext and Tor is independent of the choice of the free resolution. For, the elementary properties of these two functors see, for instancen Switzer [1, Chap. 13].

Exercise 15.13.4. If $m$ and $n$ are positive integers, we denote their greateat
common divisor by ( $m, n$ ). Verify the tables

| Ext | $\mathbb{Z}$ | $\mathbb{Z}_{n}$ |
| :---: | :---: | :---: |
| $\mathbf{Z}$ | 0 | 0 |
| $\mathbf{Z}_{m}$ | $\mathbf{Z}_{m}$ | $\mathbf{Z}_{(m, n)}$ |

| Tor | $Z$ |  |
| :---: | :---: | :---: |
| $\mathbf{Z}$ | 0 | 0 |
| $\mathbf{Z}_{m}$ | 0 | $\mathbf{Z}_{(m, n)}$ |

For example,

$$
\operatorname{Ext}\left(\mathbb{Z}_{m}, \mathbb{Z}\right)=\mathbb{Z}_{m}
$$

In terms of these completely algebraic functors, one finds the following description of the dependence of the singular theory on its coefficient group. For a proof see Spanier [1, pp. 222 and 243].

Theorem 15.14 (Universal Coefficient Theorems). For any space $X$ and Abelian group $G$,
(a) the homology of $X$ with coefficients in $G$ has a splitting:

$$
H_{q}(X ; G) \simeq H_{q}(X) \otimes G \oplus \operatorname{Tor}\left(H_{q-1}(X), G\right) ;
$$

(b) the cohomology of $X$ with coefficients in $G$ also has a splitting:

$$
H^{q}(X ; G) \simeq \operatorname{Hom}\left(H_{q}(X), G\right) \oplus \operatorname{Ext}\left(H_{q-1}(X), G\right)
$$

Applying Part (b) with $G=\mathbb{Z}$ yields the following formula for the integer cohomology in terms of the integer homology.
Corollary 15.14.1. For any space $X$ for which $H_{q}(X)$ and $H_{q-1}(X)$ are finitely generated Z-modules,

$$
H^{q}(X) \simeq F_{q} \oplus T_{q-1}
$$

where $F_{q}$ is the free part of $H_{q}(X)$ and $T_{q-1}$ is the torsion part of $H_{q-1}(X)$.
Remark. The splittings given by the universal coefficient theorems cannot be arranged to be compatible with the induced homomorphisms of maps. They are therefore often said to be unnatural splittings.

Example 15.15 (The cohomology of the unit tangent bundle of a sphere). The unit tangent bundle $S\left(T_{\Sigma^{2}}\right)$ to the 2 -sphere in $\mathbb{R}^{3}$ is a fiber bundle with fiber $S^{1}$ :

$$
\begin{gathered}
S^{1} \rightarrow S\left(T_{s^{2}}\right) \\
\\
\\
\\
S^{2}
\end{gathered}
$$

By (15.11) the $E_{2}$ term of the spectral sequence is

$$
E^{p, q}=H^{p}\left(S^{2}\right) \otimes H^{q}\left(S^{1}\right)
$$

For dimensional reasons $d_{3}=d_{4}=\cdots=0$, so $E_{3}=E_{\alpha}$. By Remark 14.20 the differential $d_{2}$ in the diagram defines the Euler class of the circle bundle $S\left(T_{s_{2}}\right)$. Since the Euler class of $S\left(T_{s^{2}}\right)$ is twice the generator of $H^{2}\left(S^{2}\right)$ (Example 11.18), this $d_{2}$ is multiplication by 2 . Thus

$$
H^{*} S\left(T_{S^{2}}\right)=\left\{\begin{array}{l}
\mathbb{Z} \text { in dimensions } 0 \text { and } 3 \\
\mathbb{Z}_{2} \text { in dimension } 2 \\
0 \text { otherwise. }
\end{array}\right.
$$

Exercise 15.15.1. Compute the cohomology of the unit tangent bundle $S\left(T_{\mathrm{s} 2}\right)$.

A point in $S\left(T_{s 2}\right)$ is specified by a unit vector in $R^{3}$ and another unit vector orthogonal to it. This can be completed to a unique orthonormal basis with positive determinant. Therefore $S\left(T_{s_{2}}\right)=S O(3)$ and we have computed above the cohomology of SO(3).

Remark 15.15.2. The special orthogonal group SO(3) comes in a different guise as $\mathbf{R P}^{3}$, as follows. We can think of $S O(3)$ as the group of all rotations about the origin in $\mathbb{R}^{3}$. Each such rotation is determined by its axis and an angle $-\pi \leq \theta \leq \pi$. In this way $S O(3)$ is parametrized by the solid 3 -ball $D^{3}$ of radius $\pi$ in $\mathbb{R}^{3}$ : a point in this 3-ball determines a unique axis and a unique angle of rotation, the axis being the line through the point and the origin, and the angle being the distance of the point from the origin. Since rotating through the angle $-\pi$ has the same effect as through $\pi$, any pair of antipodal points on the boundary of $D^{3}$ parametrize the same rotation. So $S O(3)$ is homeomorphic to $R P^{3}$.

Exercise 15.16 (The Cohomology of SO(4)). The special orthogonal group $S O(n)$ acts transitively on the unit sphere $S^{n-1}$ in $\mathbb{R}^{n}$ with stabilizer $S O(n-1)$. Therefore $S O(n) / S O(n-1)=S^{n-1}$. A group with a differentiable
structure relative to which the group operations, namely multiplication and inverse, are smooth is called a Lie group. $G L(n, \mathbb{R})$ and $S O(n)$ are examples of Lie groups (see Spivak [1, Ex. 33, p. 83]). It is a fact from the theory of Lie groups that if $H$ is a closed subgroup of a Lie group $G$, i.e., $H$ is a Lie subgroup and a closed subset of $G$, then $\pi: G \rightarrow G / H$ is a fiber bundle with fiber $H$ (Warner [1, Th. 3.58, p. 120]). Apply the spectral sequence of the fiber bundle

$$
\begin{array}{r}
S O(3) \rightarrow S O(4) \\
\downarrow \\
S^{3}
\end{array}
$$

to compute the cohomology of $S O(4)$.
Exercise 15.17 (The Cohomology of the Unitary Group). The unitary group $U(n) 3$ uis transitively on the unit sphere $S^{2 n-1}$ in $\mathbb{C}^{n}$ with stabilizer $U(n-1)$. Hence $U(n) / U(n-1)=S^{2 n-1}$. Apply the spectral sequence of the firer bundle

$$
\begin{array}{r}
U(n-1) \rightarrow U(n) \\
\downarrow \\
S^{2 n-1}
\end{array}
$$

to compute the cohomology of $U(n)$.

## The Homology Spectral Sequence

Although in this book we are primarily concerned with cohomology, for applications to homotopy theory it is frequently advantageous to use the homology spectral sequence of a fibering. Since the construction of such a spectral sequence is analogous to that for cohomology, the discussion will be brief.

Using the singular chain functor $S_{\#}$ in place of the differential form functor $\Omega^{*}$ we get a double complex $C_{*}\left(u, S_{*}\right)$ with differential operators $\partial$ and $\delta$. Define $D$ to be $\delta+(-1)^{\rho} \delta$.

As in Section 14 this double complex gives rise to a spectral sequence $\left\{E^{\boldsymbol{r}}\right\}$ which converges to the total homology $H_{D}\left\{C_{*}\left(\tilde{U}, S_{*}\right)\right\}$. Because of the directions of the arrows $\partial$ and $\delta$, the differential $d$ goes in the opposite direction as the differential of a cohomology spectral sequence; more precisely,

$$
d^{r}: E_{p, 1}^{r} \rightarrow E_{p-r, q+r-1}^{r} .
$$

By the exactness of the Mayer-Vietoris sequence (15.2) the spectral sequence is degenerate at the $E^{2}$ term and

$$
E^{2}=H_{\partial} H_{\partial}=H_{*}(X) .
$$

Hence we have the following.
Proposition 15.18. For any cover $\mathfrak{U}$ of $X$ the double complex $C_{*}\left(\mathcal{U}, S_{\ddagger}\right)$ computes the singular homology of $X$ :

$$
H_{D}\left\{C_{\psi}\left(\mathcal{U}, S_{\psi}\right)\right\}=H_{\psi}(X) .
$$

To avoid confusion with the cohomology spectral sequence, we write $r$ as a superscript and $p$ and $q$ as subscripts in the homology spectral sequence: $E_{p, q}^{\top}$.

Now suppose $\mathfrak{U}$ is a good cover of $X$. Interchanging the roles of $\partial$ and $\delta$ gives another spectral sequence which also converges to $H_{D}\left\{C_{\ddagger}\left(\mathbb{U}, S_{\psi}\right)\right\}$. This time

$$
\begin{equation*}
E^{\infty}=E^{2}=H_{\delta} H_{0}=H_{*}(\mathfrak{U}, \mathbf{Z}) \tag{15.19}
\end{equation*}
$$

where $\mathbb{Z}$ is the constant presheaf with group $\mathbb{Z}$. Compaing (15.18) with (15.19) gives the isomorphism of the singular homology to the Cech homology $H_{*}(\mathbb{U}, \mathbb{Z})$ of a good cover. Along the line of Theorem 14.18, if $\pi: E \rightarrow X$ is a fiber bundle with fiber $F$, and $X$ is a simply connected space with a good cover, then there is a spectral sequence converging to the singular homology $H_{s}(E)$ with $E_{\text {e. }}^{2}=H_{d}\left(X, H_{\alpha}(F)\right.$ ). If in addition $H_{d}(F)$ is a free $\mathbf{Z}$-module, the $E^{2}$ term is isomorphic to the tensor product $H_{\phi}(X) \otimes H_{q}(F)$ as $\mathbf{Z}$-modules. Unlike the cohomology spectral sequence, there is in general no product structure in homology.

## §16 The Path Fibration

Recall again that through $\$ 18$ we work in the category of topological spaces and continuous maps. Unless otherwise noted all cohomology groups will be assumed to have integer coefficients. Let $\pi: E \rightarrow X$ be a fiber bundle with fiber $F$ over a topological space $X$ that has a good cover $\mathbf{H}$. We have shown that there is a spectral sequence converging to the cohomology $H^{*}(E)$ of the total space, with $E_{2}$ term

$$
E_{2}^{\prime \cdot}=H^{M}\left(U, x^{-4}(F)\right),
$$

where $\mathscr{H}^{q}(F)$ is the presheaf that associates to every open set $U$ in $\mathfrak{U}$ the group $H^{q}\left(\pi^{-1} U\right) \simeq H^{q}(F)$. Now suppose $\pi: E \rightarrow X$ is simply a map, not necessarily locally trivial. One can still obtain a spectral sequence by considering the double complex of singular cochains $K=C^{*}\left(\pi^{-1} \mathfrak{u}, S^{*}\right)$ on $E$. As long as the map $\pi: E \rightarrow X$ has the property that

$$
\begin{gather*}
H^{q}\left(\pi^{-1} U\right) \simeq H^{q}(F) \text { for some fixed space } F \text { and for any contractible }  \tag{16.1}\\
\text { open set } U,
\end{gather*}
$$

then $E_{2}=H_{\delta} H_{d}(K)$ will be the same as for a fiber bundle. Since the spectral sequence is a purely algebraic way of going from $H_{\delta} H_{d}$ to $H_{D}$, which is isomorphic to $H^{*}(E)$, the spectral sequence of this double complex will again converge to $H^{*}(E)$. An example of such a map is the path fibration. As will be seen in the next few sections, Serre's application of the spectral sequence in this unexpected setting has far-reaching consequences in homotopy theory.

## The Path Fibration

Let $X$ be a topological space with a base point * and $[0,1]$ the unit interval with base point 0 . The path space of $X$ is defined to be the space $P(X)$ consisting of all the paths in $X$ with initial point *:

$$
P(X)=\{\text { maps } \mu:[0,1] \rightarrow X \mid \mu(0)=*\} .
$$

We give this space the compact open topology; i.e., a basic open set in $P(X)$ consists of all base-point preserving maps $\mu:[0,1] \rightarrow X$ such that $\mu(K) \subset U$ for a fixed compact set $K$ in $[0,1]$ and a fixed open set $U$ in $X$. There is a natural projection $\pi: P(X) \rightarrow X$ given by the endpoint of a path: $\pi(\mu)=\mu(1)$. The fiber at $p$ of this projection consists of all the path from * to $p$ (see Figure 16.1).

Figure 16.1
We now show that the map $\pi: P(X) \rightarrow X$ has the property (16.1). Let $U$ be a contractible open set containing $p$. There is a natural inclusion

$$
i: \pi^{-1}(p) \rightarrow \pi^{-1}(U)
$$

Figure 16.2
(See Figure 16.2.) Using a contraction of $U$ to $p$, we can get a map

$$
\phi: \pi^{-1}(U) \rightarrow \pi^{-1}(p)
$$

It is readily checked that $\phi$ and $i$ are homotopy inverses. Furthermoze, if $p$ and $q$ are two points in the same path component of $M$, then a fixed path from $p$ to $q$ induces a homotopy equivalence $\pi^{-2}(p) \simeq \pi^{-1}(q)$. Thus all fibers have the humotopy type of $\pi^{-1}(*)$, which is the loop space $\Omega X$ of $X$ :

$$
\Omega X=\{\mu:[0,1] \rightarrow X \mid \mu(0)=\mu(1)=*\} .
$$

So the map $\pi: P(X) \rightarrow X$ has the property $H^{*}\left(\pi^{-1} U\right) \simeq H^{*}(\Omega X)$ for any contractible $U$ in $X$.

A more general class of maps satisfying (16.1) are the fiberings or fibrations. A map $\pi: E \rightarrow X$ is called a fibering or a fibration if it satisfies the covering homotopy property :
(16.2) given a map $f: Y \dot{\rightarrow} E$ from any topological space $Y$ into $E$ and a homotopy $\hat{f}_{i}$ of $f=\pi \circ f$ in $X$, there is a homotopy $f_{t}$ of $f$ in $E$ which covers $\bar{f}_{i}$; that is, $\pi \circ f_{t}=\bar{f}_{t}$.

The covering homotopy property may be expressed in terms of the diagram

Such a fibering is sometimes called a fibering in the sense of Hurewicz, as opposed to a fibering in the sense of Serre which requires only that the covering homotopy property be satisfied for finite polyhedra $Y$. If $X$ is a pointed space with base point *, we call $\pi^{-1}(*)$ the fiber of the fibering, and for any $x$ in $X$, we call $F_{x}=\pi^{-1}(x)$ the fiber over $x$. As a convention we will assume the base space $X$ of a fibering to be connected. It is clear that the $\operatorname{map} \pi: P X \rightarrow X$ is a fibering with fiber $\Omega X$, for a homotopy in $X$ naturally induces a covering homotopy in $P X$. This fibering, called the path fibration of $X$, is fundamental in the computation of the cohomology of the loop spaces. Its total space $P X$ can be contracted to the constant path: $[0,1] \rightarrow *$.

We prove below two basic properties of a fibering, from which it will follow that (16.1) holds for a fibering.

Proposition 16.3.(a) Any two fibers of a fibering over an arcwise-connected space have the same homotopy type.
(b) For every contractible open set $U$, the inverse image $\pi^{-1} U$ has the homotopy type of the fiber $F_{a}$, where $a$ is any point in $U$.

Proof. (a) A path $\gamma(t)$ from $a$ to $b$ in $X$ may be regarded as a homotopy of the point $a$. Let $\bar{g}: F_{e} \times I \rightarrow X$ be given by $(y, t) \mapsto \gamma(t)$, where $I$ is the unit interval $[0,1]$. So we have the situation depicted in Figure 16.3. By the

$$
(y, t)
$$

Figure 16.3
covering homotopy property, there is a map $g$ which covers $\bar{g}$. The restriction $g_{1}=\left.g\right|_{\left.F_{a} \times 1\right)}$ is then a map from $F_{a}$ to $F_{b}$. Thus a path from a to $b$ induces a map from the fiber $F_{e}$ to the fiber $F_{b}$.

We will show that homotopic paths from $a$ to $b$ in $X$ induce homotopic maps from $F_{a}$ to $F_{b}$. Let $\mu$ be a path from $a$ to $b$ which is homotopic to $\gamma$, $h$ a covering homotopy of $\mu$, and $h_{1}$ the induced map from $F_{a}$ to $F_{b}$. Define $Z$ by (see Figure 16.4)

$$
Z=F_{a} \times I \times\{0\} \cup F_{a} \times I \times I
$$

and $f: Z \rightarrow E$ by

$$
\begin{aligned}
& \left.f\right|_{f_{a} \times 1 \times(0)}(y, s, 0)=y \\
& \left.f\right|_{f_{a} \times(0) \times f}(y, 0, t)=g(y, t) \\
& \left.f\right|_{f_{e} \times(1) \times(y, 1, t)}=h(y, t) .
\end{aligned}
$$

We regard the homotopy between $\gamma$ and $\mu$ in $X$ as a homotopy $\bar{G}$ of $\pi \circ f$.

Figure 16.4

By the covering homotopy property there is a covering map $G$ from $F_{a} \times I \times I$, which is homotopic to $Z \times I$, into $E$. The restriction of $G$ to $F_{s} \times I \times\{1\}$ has image in $F_{b}$. Since $\left.G\right|_{F_{t} \times(0) \times(1)}=g_{1}$ and $\left.G\right|_{r_{t} \times(1) \times(1)}=$ $h_{1},\left.G\right|_{r_{a} \times(\times(1)}$ is a homotopy in $F_{b}$ between $g_{1}$ and $h_{1}$.

Given two points $a$ and $b$ in $X$ and a path $\gamma$ from $a$ to $b$, let $u: F_{a} \rightarrow F_{b}$ be a map induced by $\gamma$ and $v: F_{b} \rightarrow F_{a}$ a map induced by $\gamma^{-1}$. Then $v \circ u$ : $F_{a} \rightarrow F_{b}$ is a map induced by $\gamma^{-1} \gamma$. Since $\gamma^{-1} \gamma$ is homotopic to the constant map to $a$, the composition $v \circ u$ is homotopic to the identity on $F_{b}$. Therefore, $F_{\Delta}$ and $F_{b}$ have the same homotopy type.
(b) Let $\gamma: U \times I \rightarrow U$ be a deformation retraction of $U$ to the point $a$. By the covering homotopy property, there is a map $g: \pi^{-1} U \times I \rightarrow \pi^{-1} U$ such that the following diagram is commutative.

We will show that $g$ gives a deformation retraction of $\pi^{-1} U$ onto the fiber $F_{a}$. Let $g_{\mathrm{t}}$ be the restriction of $g$ to $\pi^{-1} U \times\{t\}$. By identifying $\pi^{-1} U$ with $\pi^{-1} U \times\{t\}$, we may regard $g$ as a family of maps $g_{t}: \pi^{-1} U \rightarrow \pi^{-1} U$ vary-
ing with $t$ in the unit interval $I$. At $t=0$,

$$
g_{0}: \pi^{-1} U \times\{0\} \rightarrow \pi^{-1} U
$$

is the identity and at $t=1$,

$$
g_{1}: \pi^{-1} U \times\{1\} \rightarrow \pi^{-1} U
$$

has image in the fiber $F_{a}$. Hence, $g_{1}$ may be factored as $g_{1}=i \circ \phi:$

$$
\pi^{-1} U \times\{1\} \stackrel{\oplus}{\rightarrow} F_{a} \stackrel{i}{\hookrightarrow} \pi^{-1} U
$$

So via $g$ the composition $i \circ \phi$ is homotopic to the identity. To show that $\phi \circ i: F_{a} \rightarrow F_{a}$ is homotopic to the identity, consider the following diagram

Note that $\phi \circ i=\left.g \circ j\right|_{F_{0} \times(1)}$ is induced from the constant path $I \rightarrow\{a\} \in X$, since $\gamma \circ \pi \circ j(y, t)=a$ for all $t$. (The deformation retraction $\gamma$ fixes $a$ at all times.) By the proof of (a), $\phi \circ i$ is homotopic to the identity.

Remark 16.4. If we replace $F_{a}$ with any space $Y$, the argument in (a) proves that in the covering homotopy property (16.2), homotopic maps in $X$ induce homotopic covering maps in $E$.

Generalizing the fact that a simply connected space cannot have a connected covering space of more than one sheets, we have the following.

Proposition 165. Let $\pi: E \rightarrow X$ be a fibering. If $X$ is simply connected and $E$ is path connected, then the fibers are path connected.
Proof. Trivially the $E_{2}^{0,0}$ term of the fibering survives to $E_{\infty}$. Hence

$$
E_{2}^{0,0}=E_{\infty}^{0,0}=H^{0}(E)=\mathbf{Z},
$$

since $E$ is path connected. On the other hand,

$$
E_{2}^{0.0}=H^{0}\left(X, H^{0}(F)\right)=H^{0}(F)
$$

Therefore $\boldsymbol{H}^{\mathbf{0}}(\boldsymbol{F})=\mathbf{Z}$.

## The Cohomology of the Loop Space of a Sphere

As an application of the spectral sequence of the path fibration, we compute here the integer cohomology groups of the loop space $\Omega S^{\mathbf{N}}, n \geq 2$.

Example 16.6 (The 2-sphere). Since $S^{2}$ is simply connected, the spectral sequence of the path fibration

$$
\begin{array}{r}
\Omega S^{2} \rightarrow P S^{2} \\
\downarrow \\
S^{2}
\end{array}
$$

has $E_{2}$ term

$$
E_{2}^{p .4}=H^{P}\left(S^{2}, H^{q}\left(\Omega S^{2}\right)\right)
$$

So the zeroth column $E_{2}^{0.4}=H^{0}\left(S^{2}, H^{4}\left(\Omega S^{2}\right)\right)=H^{4}\left(\Omega S^{2}\right)$ is the cohomology of the fiber. By Proposition 16.5, $H^{0}\left(\Omega S^{2}\right)=\mathbb{Z}$, so the bottom row $H \xi_{2}^{0}=$ $H^{P}\left(S^{2}, H^{0}\left(\Omega S^{2}\right)\right)=H^{p}\left(S^{2}, Z\right)$ is the cohomology of the base.

By the universal coefficient theorem (15.14), all columns in $E_{2}$ except $p=0$ and $p=2$ are zero. Hence all the differentials $d_{3}, d_{4}, \ldots$ are zero and $E_{3^{p} \cdot q}^{p}=E_{\infty}^{p, 4}$. Because the path space $P S^{2}$ is contractible,

$$
E_{\infty}^{p, q}= \begin{cases}Z & (p, q)=(0,0) \\ 0 & \text { otherwisc }\end{cases}
$$

Thus $d_{2}: E_{2}^{0,1} \rightarrow E_{2}^{2,0}$ must be an isomorphism. It follows that $H^{1}\left(\Omega S^{2}\right)=\mathbf{Z}$. But then

$$
E_{2}^{2,1}=H^{2}\left(S^{2}, H^{1}\left(\Omega S^{2}\right)\right)=H^{2}\left(S^{2}, Z\right)=\mathbb{Z}
$$

Since $d_{2}: E_{2}^{0,2} \rightarrow E_{2}^{2,1}$ is an isomorphism, $H^{2}\left(\Omega S^{2}\right)=Z$. Working our way up, we find $H^{q}\left(\Omega S^{\mathbf{2}}\right)=\mathbf{Z}$ in every dimension $q$.

Example 16.7 (The 3 -sphere). In the $E_{2}$ term of the fibering

the nonzero columns are $p=0$ and $p=3$. For dimension reasons $d_{2}=0$ and $d_{4}=d_{5}=\cdots=0$. Because the total space is contractible, $d_{3}$ is an isomorphism except at $E_{3}^{0.0}$. Therefore,

$$
H^{*}\left(\Omega S^{3}\right)= \begin{cases}Z & \text { in even dimensions } \\ 0 & \text { otherwise. }\end{cases}
$$

Similarly we find that in general

$$
H^{*}\left(\Omega S^{n}\right)= \begin{cases}\mathbb{Z} & \text { in dimensions } 0, n-1,2(n-1), \ldots \\ 0 & \text { otherwise: }\end{cases}
$$

Next we examine the ring structure of $H^{*}\left(\Omega S^{\prime \prime}\right)$. We start with $\Omega S^{2}$. Let $u$ be a generator of $E_{2}^{2,0}=H^{2}\left(S^{2}\right)$ and let $x$ be the generator of $H^{1}\left(\Omega S^{1}\right)$ which is mapped to $u$ by $d_{2}$. For simplicity we occasionally write $d$ for $d_{2}$. By Example 16.6, the differential $d_{2}$ is an isomorphism. Note that $x$ commutes with $u$ because $E_{2}$ is the tensor product $H^{*}\left(\Omega S^{2}\right) \otimes H^{*}\left(S^{2}\right)$. ( $x$ is actually $x \otimes 1$ and $u$ is $1 \otimes u$.)

| 4 | $\frac{e^{2}}{2}$ |  |
| :---: | :---: | :---: |
| 3 | ex | exu |
| 2 | $e$ | eu |
| 1 |  |  |
| 0 | 1 |  |

Since $d_{2}\left(x^{2}\right)=\left(d_{2} x\right) \cdot x-x \cdot d_{2} x=u x-x u=0$, we have $x^{2}=0$. Thus the generator $e$ in $H^{2}\left(\Omega S^{2}\right)$ which maps to $x u$ is algebraically independent of $x$. Since $d(e x)=e u$, the product $e x$ is a generator in dimension 3. Similarly, $d\left(e^{2}\right)=2 e x u$ so that $e^{2} / 2$ is a generator in dimension $4 ; d\left(\left(e^{2} / 2\right) x\right)=\left(e^{2} / 2\right) u$. so that $\left(e^{2} / 2\right) \cdot x$ is a generator in dimension 5 . By induction we shall prove

$$
\frac{e^{k}}{k!} \text { is a generator in dimension } 2 k
$$

and

$$
\frac{e^{k}}{k!} x \text { is a generator in dimension } 2 k+1
$$

Proof. Suppose the claim is true for $k-1$. Since

$$
d \frac{e^{k}}{k!}=\frac{e^{k-1}}{(k-1)!} d e=\frac{e^{k-1}}{(k-1)!} x u,
$$

which is a generator of $E_{2}^{2,2 k-1}$, the element $e^{k} / k$ ! is a generator of $H^{2 k}\left(\Omega S^{2}\right)$. Similarly, since

$$
d\left(\frac{e^{k}}{k!} x\right)=\frac{e^{k-1}}{(k-1)!} x u \cdot x+\frac{e^{k}}{k!} u=\frac{e^{k}}{k!} u
$$

which is a generator of $E_{2}^{2,2 k}$, the element $\left(e^{k} / k!\right) x$ is a generator of $H^{2 k+1}\left(\Omega S^{2}\right)$.

By definition the exterior algebra $E(x)$ is the ring $\mathbb{Z}[x] /\left(x^{2}\right)$ and the divided polynomial algebra $Z_{y}(e)$ with generator $e$ is the $\mathbb{Z}$-algebra with additive basis $\left\{1, e, e^{2} / 2!, e^{3} / 3!, \ldots\right\}$. Hence

$$
H^{*}\left(\Omega S^{2}\right)=E(x) \otimes Z_{\gamma}(e)
$$

where $\operatorname{dim} x=1$ and $\operatorname{dim} e=2$.
Now consider $H^{*}\left(\Omega S^{n}\right)$ for $n$ odd. Let $u$ be a generator of $H^{n}\left(S^{n}\right)$ and $e$ the generator of $H^{n-1}\left(\Omega S^{n}\right)$ which maps to $u$ under the isomorphism $d_{2}$. Since $d_{n}\left(e^{2}\right)=2 e u, e^{2} / 2$ is a generator in dimension $2(n-1)$. In general if $e^{k} / k!$ is a generator in dimension $k(n-1)$, then $d_{k}\left(e^{k+1} /(k+1)!\right)=\left(e^{k} / k!\right) \mu$ so that $e^{k+1} /(k+1)$ ! is a generator in dimension $(k+1)(n-1)$.

This shows that for $n$ odd,

$$
H^{*}\left(\Omega S^{*}\right)=Z_{\lambda}(e), \quad \operatorname{dim} e=n-1
$$

By a computation similar to that of $H^{*}\left(\Omega S^{\mathbf{2}}\right)$, we see that for $n$ even,

$$
H^{*}\left(\dot{\Omega} S^{\prime}\right)=E(x) \otimes Z(e), \quad \operatorname{dim} x=n-1, \quad \operatorname{dim} e=2(n-1)
$$

## $\S 17$ Review of Homotopy Theory

To pave the way for later applications of the spectral sequence, we give in this section a brief account of homotopy theory. Following the definitions and basic properties of the homotopy groups, we compute some lowdimensional homotopy groups of the spheres. The geometrical ideas in this computation lead to the homotopy properties of attaching cells. A space built up from a collection of points by attaching cells is called a $C W$ complex. To show that every manifold has the homotopy type of a $C W$ complex, we make a digression into Morse theory. Returning to the main topic, we next discuss the relation between homotopy and homology, and indicate a proof of the Hurewicz isomorphism theorem using the homology spectral sequence. The homotopy groups of the sphere, $\pi_{d}\left(S^{\prime \prime}\right), q \leq n$, are immediate corollaries. Finally, venturing into the next nontrivial homotopy group, $\pi_{3}\left(S^{2}\right)$, we discuss the Hopf invariant in terms of differential forms. Some of the general references for homotopy theory are Hu[1], Steenrod [1], and Whitehead [1].

## Homotopy Groups

Let $X$ be a topological space with a base point *. For $q \geq 1$ the $q$ th homotopy group $\pi_{e}(X)$ of $X$ is defined to be the homotopy classes of maps from the $q$-cube $N$ to $X$. which send the faces $N$. to $\Gamma$ to the base point of $X$. Equivalently $\pi_{q}(X)$ may be regarded as the homotopy classes of base-point preserving maps from the $q$-sphere $S$ to $X$. The group operation on $\pi_{f}(X)$ is defined as follows (see Figure 17.1). If $\alpha$ and $\beta$ are maps from $\Gamma^{N}$ to $X$, representing $[\alpha]$ and $[\beta]$ in $\pi_{q}(X)$, then the product $[\alpha][\beta]$ is the homotopy class of the map

$$
\gamma\left(t_{1}, \ldots, t_{4}\right)= \begin{cases}\alpha\left(2 t_{1}, t_{2}, \ldots, t_{4}\right) & \text { for } 0 \leq t_{1} \leq \frac{1}{2} \\ \beta\left(2 t_{1}-1, t_{2}, \ldots, t_{4}\right) & \text { for } \frac{1}{2} \leq t_{1} \leq 1 .\end{cases}
$$

We recall here some basic properties of the homotopy groupe.

Figure 17.1
Proposition 17.1. (a) $\pi_{q}(X \times Y)=\pi_{q}(X) \times \pi_{q}(\eta)$.
(b) $\pi_{q}(X)$ is Abelian for $q>1$.

Proof. (a) is clear since every map from $I^{4}$ into $X \times Y$ is of the form ( $f_{1}, f_{2}$ ) where $f_{1}$ is a map into $X$ and $f_{2}$ is a map into $Y$. Furthermore, since $\left(f_{1}, f_{2}\right)\left(g_{1}, g_{2}\right)=\left(f_{1} g_{1}, f_{2} g_{2}\right)$, the bijection in (a) is actually a group isomorphism. To prove (b), let $[\alpha]$ and $[\beta]$ be two clements of $\pi_{\&}(X)$. We represent $\alpha \beta$ by

$\alpha \beta$ is homotopic to the map $\delta$ from $\Gamma$ to $X$ given by

$\delta$ is in turn homotopic to

and finally to

Proposition 17.2. $\pi_{q-1}(\Omega X)=\pi_{q}(X), q \geq 2$.
Sketch of Proof. Elements of $\pi_{2}(X)$ are given by maps of the square $I^{2}$ into $X$ which send the boundary $\dot{I}^{2}$ to the base point *. Such a map may be viewed as a pencil of loops in $X$, i.e., a map from the unit interval into $\Omega X$. Therefore, $\pi_{2}(X)=\pi_{1}(\Omega X)$. The general case is similar; we view a map from $F^{F}$ to $X$ as a map from $\Gamma^{T^{-1}}$ to $\Omega X$.

It is often useful to introduce $\pi_{0}(X)$, which is defined to be the set of all path components of $X$. It has a distinguished element, namely the path component containing the base point of $X$. This component is the base point of $\pi_{0}(X)$. For a manifold the path components are the same as the connected components (Dugundji [1, Theorem IV.5.5, p. 116]).

Recall that a Lie group is a manifold endowed with a group structure such that the group operations-multiplication and the inverse operationare smooth functions. Although $\pi_{0}(X)$ is in general not a group, if $G$ is a Lie group, then $\pi_{0}(G)$ is a group. This follows from the following proposition.

Proposition 17.3. The identity component $H$ of a Lie group $G$ is a normal subgroup of $G$. Therefore, $\pi_{0}(G)=G / H$ is a group.
Proof. Let $a, b$ be in $H$. Since the continuous image of a connected set is connected, $b \boldsymbol{H}$ is a connected set having a nonempty intersection with $\boldsymbol{H}$.

Hence $b H \subset H$ : It follows that $a b H \subset a H \subset H$, so $a b$ is in $H$. Similarly $a^{-1} H$ is a connected set having a nonempty intersection with $H$, since 1 is in $a^{-1} H$; so $a^{-1} H \subset H$ and $a^{-1}$ is also in $H$. This shows that $H$ is a subgroup of $G$.

Let $g$ be an element of $G$. Since $g \mathrm{Hg}^{-1}$ is a connected set containing 1 , by the same reasoning as above, $g \mathrm{Hg}^{-1} \subset H$. Thus $H$ is normal.

Because multiplication by $g$ is a homeomorphism, the coset $g H$ is connected. Since distinct cosets are disjoint, $G / H$ consists of precisely the connected components of $G$. Therefore, $\pi_{0}(G)=G / H$.

Let $\pi: E \rightarrow B$ be a (base-point preserving) fibering with fiber $F$. Then there is an exact sequence of homotopy groups, called the homotopy sequence of the fibering (Steenrod [1,'p. 91]):

$$
\begin{align*}
& \cdots \rightarrow \pi_{d}(F) \xrightarrow{i_{4}} \pi_{d}(E) \xrightarrow{\pi_{s}} \pi_{d}(B) \xrightarrow{0} \pi_{e-1}(F) \rightarrow \cdots  \tag{17.4}\\
& \cdots \rightarrow \pi_{0}(E) \rightarrow \pi_{0}(B) \rightarrow 0
\end{align*}
$$

In this exact sequence the last three maps are not group homomorphisms, but only set maps. The kernel of a set map between pointed sets is by definition the inverse image of the base point. Exactness in this context is given by the same condition', as before: "the image equals the kernel." The maps $i_{*}$ and $\pi_{*}$ are the maps induced by the inclusion $i: F \rightarrow E$ and the projection $\pi: E \rightarrow B$ respectively. Here we regard $F$ as the fiber over the base point of $B$. To describe $\partial$ we use the covering homotopy property of a fibering. For simplicity consider first $q=1$. A loop $a: I^{1} \rightarrow B$ from the upit interval to $B$, representing an element of $\pi_{1}(B)$, may be lifted to a path $\bar{\alpha}$ in $E$ with $\bar{\alpha}(0)$ being the base point of $F$. Then $\partial[\propto]$ is given by $\mathcal{M}(1)$ in $\pi_{0}(F)$. More generally let $I^{4^{-1}} \subset I^{4}$ be the inclusion

$$
\left(t_{1}, \ldots, t_{q-1}\right) \mapsto\left(t_{1}, \ldots, t_{q-1}, 0\right) .
$$

A map $\alpha: I^{Q} \rightarrow B$ representing an element of $\pi(B)$ may be regarded as a homotopy of $\left.\alpha\right|_{R^{-1}}$ in $B$. Let the constant map $*: I^{-1} \rightarrow E$ from $I^{a^{-1}}$ to the base point of $F$ be the map that covers $\left.\alpha\right|_{r^{-1}}:\left(t_{1}, \ldots, t_{q-1}, 0\right) \rightarrow B$. By ; the covering homotopy property, there is a homotopy upstairs $\bar{\alpha}: I^{4} \rightarrow E$ which covers $\alpha$ and such that $\left.\bar{\alpha}\right|_{1^{-1}}=*$. Then $\partial[\alpha]$ is the homotopy class of the $\operatorname{map} \bar{\alpha}:\left(t_{1}, \ldots, t_{q-1}, 1\right) \rightarrow F$. By Remark 16.4, $\partial[\alpha]$ is well-defined.

Example 17.5. A covering space $\pi: E \rightarrow B$ is a fibering with discrete fibers. By the homotopy sequence of the fibering.

$$
\pi_{d}(E)=\pi_{d}(B) \quad \text { for } \quad q \geq 2
$$

and

$$
\pi_{1}(E) \hookrightarrow \pi_{1}(B) .
$$

Warnng 17.6 (Dependence on base points). Consider the homotopy groups $\pi_{f}(X, x)$ and $\pi_{f}(X, y)$ of a path-connected space $X$, computed relative to two different points $x$ and $y$. A path $\gamma$ from $x$ to $y$ induces by conjugation a map from the loop space $\Omega_{x} X$ to the loop space $\Omega_{y} X$ :

$$
\lambda \mapsto \gamma \lambda y^{-1} \quad \text { for any } \lambda \text { in } \Omega_{x} X .
$$

This in turn induces a map of homotopy groups

$$
\begin{gathered}
\gamma_{*}: \pi_{q-1}\left(\Omega_{x} X, \tilde{x}\right) \rightarrow x_{q-1}(\Omega, X, \tilde{y}) \\
x_{f}(X, x)
\end{gathered}
$$

where $\vec{x}$ and $\bar{y}$ are the constant maps to $x$ and $y$. The map $\gamma_{*}$ is clearly an isomorphism, with inverse given by $\left(\gamma^{-1}\right)_{4}$ :

We can describe $\gamma_{s}$ explicitly as follows. Let [ $\alpha$ ] be an element of $\pi_{9}(X, x)$. Define a map $F$ to be $\alpha$ on the bottom face of the cube $I^{+1}$ and $\gamma$ on the vertical faces (Figure 17.2 (a)); more precisely, if $\left(u_{0} t\right) \in I^{4} \times I_{\text {- }}=$ $I^{i+1}$, then

$$
F(u, 0)=\alpha(u) \text { for all } u \text { in } I^{4}
$$

and

$$
F(m, t)=\gamma(t) \text { for all } u \text { in } \partial I^{\varphi}
$$

Figure 17.2 a )
By the box principle from obstruction theory (which states that a map from the union of all but one face of a cube into any space can be extended to the whole cube), the map $F$ can be extended to the entire $I^{++1}$. Its re striction to the top face represents $\gamma_{*}[\alpha]$.

One checks easily that $\gamma_{*}$ is independent of the homotopy class of $\gamma$ amongst the paths from $x$ to $y$, so that when we take $x=y$, the assignment $\gamma \mapsto \gamma_{*}$ may be thought of as an action of $\pi_{1}(X, x)$ on $x_{d}(X, x)$. Only if this
action is trivial, can one speak unambiguously of $\pi_{8}(X)$ without reference to a base point. In that case one can also identify the free homotopy classes of maps $\left[S^{\prime}, X\right]$ with $\pi_{f}(X)$; here by a free homotopy we mean a homotopy that does not necessarily preserve the base points. In general, however, [ $\left.S^{\natural}, X\right]$ is not a group and its relation to $\pi_{q}(X)$ is given by the following

Proposition 17.6.1. Let $X$ be a path-connected space. The inctusion of basepoint preserving maps into the set of all maps induces a bjection

$$
\pi_{4}(X, x) / \pi_{1}(X, x) \underset{\rightarrow}{\sim}\left[S^{4}, X\right]
$$

where the notation on the left indicates the equidalence relation $[\alpha] \sim \gamma_{*}[\alpha]$ for $[\gamma]$ in $\pi_{1}(X, x)$.

Proof. Let $h: \pi_{f}(X, x) \rightarrow[S Y, X]$ be induced by the inclusion of base point preserving maps into the set of all maps. If $[\alpha] \in X_{1}(X, x)$ and $[\gamma] \in \pi_{1}(X, x)$, it is laborious but not difficult to write down an explicit free homotopy between $\alpha$ and $\gamma_{*} \alpha$ (see Figure 17.2 (b) for the casce $q=1$ and $q=2$ ). Hence $h$ factors through the action of $\pi_{i}(X, x)$ on $\pi_{f}(X, x)$ and

Figure 17.2(b)
defines a map
$H: \pi_{q}(X ; x) / \pi_{1}(X, x) \rightarrow\left[S^{\dagger}, X\right]$.

Figure 17.2(c)
Since $X$ is path connected, any map in $\left[S^{9}, X\right]$ can be deformed to a base-point preserving map. So $H$ is surjective. To show injectivity, suppose $[\alpha]$ in $\pi_{q}(X, x)$ is null-homotopic in [ $\left.S^{\Phi}, X\right]$. This means there is a map $F: I^{a+1} \rightarrow X$ such that

$$
\begin{aligned}
\left.F\right|_{\text {cop finc }} & =\alpha_{1} \\
\left.F\right|_{\text {bottoem foce }} & =\bar{x}_{,}
\end{aligned}
$$

and $F$ is constant on the boundary of each horizontal slice (Figure 17.2 (c)). Let $\gamma$ be the restriction of $F$ to a vertical segment. Then $\alpha=\gamma_{*}(\bar{x})$. Therefore, $H$ is injective.

## The Relative Homotopy Sequence

Let $X$ be a space with base point *, and $A$ a subset of $X$ (See Figure 17.3). Denote by $\Omega_{*}^{1}$ the space of all paths from * to $A$. The endpoint map $e: \Omega_{*}^{\boldsymbol{A}} \rightarrow A$ gives a fibering

$$
\boldsymbol{\Omega} X \rightarrow \mathbf{\Omega}_{\downarrow}^{\mathbf{A}}
$$

A.

The homotopy sequence of this fibering is

$$
\begin{aligned}
\cdots \rightarrow \pi_{4}(A) \rightarrow \pi_{4-1}(\Omega X) \rightarrow \pi_{4-1}\left(\Omega_{4}^{A}\right) & \rightarrow \pi_{4-1}(A) \rightarrow \cdots \\
& \cdots \rightarrow \pi_{0}\left(\mathbf{\Omega}_{*}^{A}\right) \rightarrow \pi_{0}(A) \rightarrow 0
\end{aligned}
$$

Figure 17.3
We define the relative homotopy group $\pi_{A}(X, A)$ to be $\pi_{9-1}\left(\Omega_{\ddagger}^{A}\right)$. Then the sequence above becomes the relative homotopy sequence of $A$ in $X$ :,

$$
\begin{align*}
\cdots \rightarrow \pi_{d}(A) \rightarrow \pi_{d}(X) \longrightarrow \pi_{d}(X, A) & \rightarrow \pi_{4-1}(A) \rightarrow \cdots  \tag{17.7}\\
\cdots & \rightarrow \pi_{1}(X, A) \rightarrow \pi_{0}(A) \rightarrow 0 .
\end{align*}
$$

Observe that $\pi_{q}(X, A)$ is an Abelian group for $q \geq 3, \pi_{2}(X, A)$ is a group but in general not Abelian, while $\pi_{1}(X, A)$ is only a set.

## Some Homotopy Groups of the Spheres

In this section we will compute $\pi\left(S^{\prime \prime}\right)$ for $q \leq n$. Although these homotopy groups are immediate from the Hurewicz isomorphism theorem (17.21), the geometric proof presented here is important in being the pattern for later discussions of the homotopy properties of attaching cells (17.11).

Proposition 178 Every continuous map $f: M \rightarrow N$ between two manifolds is continuously homotopic to a differentiable map.

Proof. We first note that if $f: M \rightarrow \mathbf{R}$ is a continuous function and $\varepsilon$ a positive number, then there is a differentiable real-valued function $h$ on $M$ with $|f-h|<\varepsilon$. This is more or less clear from the fact that via its graph, $f$ may be regarded as a continuous section of the trivial bundle $M \times R$ over $M$; in any $\varepsilon$-neighborhood of $f$ there is a differentiable section $h$ and because the $\varepsilon$-neighborhood of $f$ may be continuously deformed onto $f, h$ is con-1 tinuously homotopic to $f$ (see Figure 17.4). Indeed, to be more explicit, this differentiable section $h$ can be given by successively averaging the values of $f$ over small disks.

Next consider a continuous map $f: M \rightarrow N$ of manifolds. By the Whitney embedding theorem (see, for instance, de Rham [1, p. 12]) there is a differentiable embedding $g: N \rightarrow \mathbf{R}^{\boldsymbol{n}}$. If

$$
g \circ f: M \rightarrow g(N) \subset \mathbf{R}^{n}
$$

is homotopic to a differentiable map, then so is

$$
f=g^{-1} \circ(g \circ f): M \rightarrow N
$$

Figure 17.4
So we may assume at the outset that $N$ is a submanifold of an Euclidean space $\mathbb{R}^{n}$. Then the map $f$ is given by continuous real-valued functions ( $f_{1}$, $\ldots, f_{n}$ ). As noted above, each coordinate function $f_{i}$ can be approximated by a differentiable function $h_{i}$ to within $\varepsilon$, and $f_{i}$ is continuously homotopic to $h_{i}$. Thus we get a differentiable map $h: M \rightarrow \mathbb{R}^{n}$ whose image is in some tubular neighborhood $T$ of $N$. But every tubular neighborhood of $N$ can be deformed to $N$ via a differentiable map $k: T \rightarrow N$ (Figure 17.5). This gives a differentiable map $k=h: M \rightarrow N$ which is homotopic to $f$.

Figure 17.5
Corollary 17.8.1. Let $M$ be a manifold. Then the homotopy groups of $M$ in the $C^{\infty}$ sense are the same as the homotopy groups of $M$ in the continuous sense.

Proposition 17.9. $\pi_{q}\left(S^{n}\right)=0$, for $q<n$.
Proof. Let $f$ be a continuous map from $l^{f}$ to $S^{n}$, representing an element of $\pi_{d}\left(S^{n}\right)$. By the lemma above, we may assume $f$ differentiable. Hence Sard's
theorem applies. Because $q$ is strictly less than $n$, the image of $f$ are all critical values. By Sard's theorem $f$ cannot be surjective. Choose a point $P$ not in the image of $f$ and let $c$ be a contraction of $S^{n}-\{P\}$ to the antipodal point $Q$ of $P$ (Figure 17.6):

$$
\begin{aligned}
& c_{1}: S^{n}-\{P\} \rightarrow S^{n}-\{P\}, t \in[0,1] \\
& c_{q}=\text { identity } \\
& G_{1}=\text { constant map } Q .
\end{aligned}
$$

Then $c_{t} \circ f$ is a hómotopy between $f$ and the constant map Q. Therefore, $\pi_{q}\left(S^{n}\right)=0$ for $q<n$.

Figure 17.6
Proposition 17.10. $\pi_{N}\left(S^{n}\right)=\mathbb{Z}$.
We will indicate here the main ideas in the geometrical proof of this statement, omitting some technical details.

Recall that to every map from $S^{n}$ to $S^{n}$ one can associate an integer called its degree. Since the degree is a homotopy invariant, it gives a map deg : $\pi_{m}\left(S^{4}\right) \rightarrow \mathbb{Z}$. There are two key lemmas.

Lemm 17.10.1. The map deg : $\pi_{N}\left(S^{n \prime}\right) \rightarrow Z$ is a group homomorphism; that is,

$$
\operatorname{deg}[f g]=\operatorname{deg}[f]+\operatorname{deg}[g] .
$$

Lemma 17.10.2 Two maps from $S^{n}$ to $S^{n}$ of the same degrce can be deformed into each other.

The surjectivity of deg follows immediately from Lemma 17.10.1, since if $f$ is the identity map, then $\operatorname{deg}\left(f^{\boldsymbol{k}}\right)=\boldsymbol{k}$, for any integer $\boldsymbol{k}$; the injectivity follows from (17.10.2).

To prove these lemmas we will' deform any map $f: S^{n} \rightarrow S^{n}$ into a normal form as follows. By the inverse function theorem $f$ is a local diffeomorphism around a regular point. By Sard's theorem regular values exist. Let $U$ be an open set around a regular value so that $f^{-1}(U)$ consists of finitely many disjoint open sets, $U_{1}, \ldots, U_{r}$, each of which $f$ maps diffeo-

Figure 17.7
morphically onto $U$ (Figure 17.7). Choose the base point * of $S^{*}$ to be not in $U$. We deform the map $f$ by deforming $U$ in such a way that the complement of $U$ goes into $*$. The deformed $f$ then maps the complement of $\bigcup_{i=1}^{k} U_{i}$ to $*$ Each $U_{i}$ comes with a multiplicity of $\pm 1$ depending on whether $f$ is orientation preserving or reversing on $U_{i}$. The degree of $f$ is the sum of these multiplicities. Given two maps $f$ and $g$ from $S^{n}$ to $S^{n}$, we deform each as above, choosing $U$ to be a neighborhood of a regular value of both $f$ and $g$. By summing the multiplicities of the inverse images of $U$, we see that $\operatorname{deg}(f g)=\operatorname{deg} f+\operatorname{deg} g$ (Figure 17.8). This proves Lemma 17.10.1.

To bring a map $f: S^{n} \rightarrow S^{n}$ into what we consider its normal form requires one more step. If $U_{i}$ and $U_{j}$ have multiplicities +1 and -1 respectively, we join $U_{i}$ to $U_{j}$ with a path. It is plausible that $f$ can be deformed further so that it maps $U_{i} \cup U_{j}$ to the base point *, since $f$ wraps $U_{i}$ around the sphere one way and $U_{j}$ the reverse way. For $S^{1}$ this is clear.

Figure 17.8

The general case is where we wave our hands. The details are quite involved and can be found in Whitney [1]. In this way pairs of open sets with opposite multiplicities are cancelled out. In the normal form, if $f$ has degree $\pm k$, then there are exactly $k$ open sets, $U_{1}, \ldots, U_{k}$, with all +1 multiplicities or all -1 multiplicities. Hence two maps from $S^{\text {m }}$ to $S^{\text {m }}$ of the same degree can be deformed into each other.

## Attaching Cells

Let $e^{n}$ be the closed $n$-disk and $S^{n-1}$ its boundary. Given a space $X$ and a $\operatorname{map} f: S^{n^{-1}} \rightarrow X$, the space $Y$ obtained from $X$ by attaching the $n$-cell $e^{*}$ via $f$ is by definition (see Figure 17.9)

$$
Y=X \cup_{f} e^{n}=X \amalg e^{n} / f(u) \sim u_{,} \text {for } u \in S^{n-1}
$$

Figure 17.9
For example, the 2 -sphere is obtained from a point by attaching a 2-cell (Figure 17.10):

$$
S^{2}=p \cup e^{2}
$$

Figure 17.10
It is easy to show that if $f$ and $g$ are homotopic maps from $S^{n-1}$ to $X$, then $X \cup_{f} e^{\prime \prime}$ and $X \cup_{f} e^{2}$ have the same homotopy type (see Bott and Mather [1, Prop. 1, p. 466] for an explicit homotopy). The moet fundamental homotopy property of attaching an $n$-coll is the following.

Propocition 17.11. Attaching an n-cell to a space $X$ does not alter the homotopy in dimensions strictly less than $n-1$, but may kill elements in $\pi_{n-1}(X)$;
more precisely, the inclusion $X \hookrightarrow X \cup e^{n}$ induces isomorphisms

$$
\pi_{q}(X) \nrightarrow \pi_{q}\left(X \cup e^{n}\right) \quad \text { for } q<n-1
$$

and a surjection

$$
\pi_{n-1}(X) \rightarrow \pi_{n-1}\left(X \cup e^{n}\right) .
$$

Proof. Assume $q \leq n-1$ and let $f: S^{q} \rightarrow X \cup e^{n}$ be a continuous basepoint preserving map. We would like first of all to show that $f$ is homotopic to some map whose image does not contain all of $e^{n}$. If $f$ is differentiable and $X u_{f} e^{n}$ is a manifold, this follows immediately from Sard's theorem. In fact, as long as $f$ is differentiable on some submanifold of $S^{\natural}$ that maps into $e^{n}$, the same conclusion holds. As in the proof of Proposition 17.8 this can always be arranged by moving the given $f$ in its homotopy class. So we may assume that $f$ does not surject onto $e^{n}$. Choose a point $p$ not in the image and fix a retraction $c_{1}$ of $\left(e^{n}-\{p\}\right)$ to the boundary of $e^{n}$. This gives a retraction $c_{t}$ of $X \cup\left(e^{n}-\{p\}\right)$ to $x$. Via $c_{t} \circ f$, the map $f$ is homotopic in $X \cup e^{n}$ to a map from $S^{q}$ to $X$ (Figure 17.11). Hence $\pi_{q}(X) \rightarrow \pi_{q}\left(X \cup e^{n}\right.$ ) is surjective for $q \leq n-1$.

Figure 17.11
Now assume $q \leq n-2$. To show injectivity let $f$ and $g$ be two maps representing elements of $\pi_{q}(X)$ which have the same image in $\pi_{q}\left(X \cup e^{n}\right)$. Let $F: S^{\natural} \times I \rightarrow X \cup e^{\pi}$ be a homotopy in $X \cup e^{n}$ between $f$ and $g$. Since the dimension of $S^{\natural} \times I$ is less than $n$, again we can deform $F$ so that its •

Figure 17.12
image does not contain all of $e^{n}$. Reasoning as before, we find maps

$$
c_{t} \circ F: S^{\varphi} \times I \rightarrow X \cup e^{n}
$$

such that $c_{1} \circ F: S^{4} \times\{1\} \rightarrow X$ is a homotopy between $f$ and $g$ which lies in $X$ (Figure 17.12). Therefore $[f]=[g]$ as elements of $\pi_{q}(X)$.

As for homology we have the following:
Proposition 17.12. Attaching an $n$-cell to a space $X$ via a map $f$ does not alter the homology except possibly in dimensions $n-1$ and $n$. Writing $X_{f}$ for $X \cup_{f} e^{n}$, there is an exact sequence

$$
0 \rightarrow H_{n}(X) \rightarrow H_{n}\left(X_{f}\right) \rightarrow \mathbb{Z} \xrightarrow{f_{*}} H_{n-1}(X) \rightarrow H_{n-1}\left(X_{f}\right) \rightarrow 0
$$

where $f_{*}: H_{n-1}\left(S^{n-1}\right) \rightarrow H_{n-1}(X)$ is the induced map. So the inclusion $X \hookrightarrow$ $X_{\text {s }}$ induces a surjection in dimension $n-1$ and an injection in dimension $n$

Proof. Let $U$ be $X_{f}-\{p\}$ where $p$ is the origin of $e^{n}$, and let $V$ be $\left\{x \in e^{n} \mid\right.$ $\left.\|x\|<\frac{1}{2}\right\}$. Then $U$ is homotopic to $X, V$ is contractible, and $\{U, V\}$ is an open cover of $X_{f}$. By the Mayer-Vietoris sequence (15.6), the following is exact

$$
\cdots \rightarrow H_{q}\left(S^{n-1}\right) \rightarrow H_{d}(X) \oplus H_{q}(V) \rightarrow H_{d}\left(X_{f}\right) \rightarrow H_{q}\left(S^{n-1}\right) \rightarrow \cdots .
$$

So for $q \neq n-1$ or $n, H_{q}\left(X_{f}\right)=H_{q}(X)$. For $q=n$, we have

$$
0 \rightarrow H_{n}(X) \rightarrow H_{n}\left(X_{f}\right) \rightarrow H_{n-1}\left(S^{n-1}\right) \xrightarrow{S_{*}} H_{n-1}(X) \rightarrow H_{n-1}\left(X_{f}\right) \rightarrow 0 .
$$

A CW complex is a space $Y$ built up from a collection of points by the successive attaching of cells; the topology of $Y$ is required to be the socalled weak topology: a set in $Y$ is closed if and only if its intersection with every cell is closed. (By a cell we mean a closed cell.) The cells of dimension at most $n$ in a $C W$ complex $Y$ together comprise the $n$-skeleton of $Y$. Clearly every triangularizable space is a $C W$ complex. Every manifold is also a $C W$ complex; this is most readily seen in the framework of Morse theory, as we will show in the next subsection.

For us the importance of the $C W$ complexes comes from the following proposition.

Proposition 17.13. Every CW complex is homotopy equivalent to a space with a good cover.

Hence the entire machinery of the spectral sequence that we have developed applies to $C W$ complexes. This proposition follows from the nontrivial fact that every CW complex has the homotapy type of a simplicial complex (Gray
[1, Cor. 16.44, p. 149, and Cor. 21.15, p. 206] or Lundell and Weingram [1, Cor. 4.7, p. 131]), for the open star of the simplicial complex is a good cover.

## Digression on Morse Theory

Using Morse theory, it can be shown that every differentiable manifold has the homotopy type of a CW complex (see Milnor [2, p. 36]). The goal of this section is to prove this for the simpler case of a compact differentiable manifold.

Let $f$ be a smooth real-valued function on a manifold $M$. A critical point of $f$ is a point $p$ where $d f=0$; in terms of local coordinates $x_{1}, \ldots, x_{n}$ centered at $p$, the condition $d f(p)=\sum\left(\partial f / \partial x_{i}\right)(p) d x_{i}=0$ is equivalent to the vanishing of all the partial derivatives $\left(\partial f / \partial x_{i}\right)(p)$. The image $f(p)$ of a critical point is called a critical value. Note that the definition of a critical point given here is a special case of the more general definition preceding Theorem 4.11 for a map between manifolds. A critical point is nondegenerate if for some coordinate system $x_{1}, \ldots, x_{n}$ centered at $p$, the matrix of second partials, $\left(\left(\partial^{2} f / \partial x_{1} \partial x_{j}\right)(p)\right)$, is nonsingular; this matrix is called the Hessian of $f$ relative to the'coordinate system $x_{1}, \ldots, x_{n}$ at $p$. The notion of a nondegenerate critical point is independent of the choice of coordinate systems, for if $y_{1}, \ldots, y_{n}$ is another coordinate system centered at $p$, then

$$
\text { , } \frac{\partial f}{\partial y_{l}}=\sum_{j} \frac{\partial f}{d x_{j}} \frac{\partial x_{j}}{\partial y_{\epsilon}}
$$

and

$$
\frac{\partial^{2} f}{\partial y_{k} \partial y_{6}}=\sum_{i, j} \frac{\partial^{2} f}{\partial x_{i} \partial x_{j}} \frac{\partial x_{i}}{\partial y_{k}} \frac{\partial x_{j}}{\partial y_{l}}+\sum_{j} \frac{\partial f}{\partial x_{j}} \frac{\partial^{2} x_{j}}{\partial y_{k}} \partial y_{j}
$$

At $p, \partial f / \partial x_{j}=0$, so that

$$
\frac{\partial^{2} f}{\partial y_{k} \partial y_{g}}=\sum_{i, j} \frac{\partial^{2} f}{\partial x_{i} \partial x_{j}} \frac{\partial x_{i}}{\partial y_{k}} \frac{\partial x_{j}}{\partial y_{g}}
$$

In matrix notation

$$
H(y)=J^{t} H(x) J
$$

where $H(x)$ is the Hessian of $f$ relative to the coordinate system $x_{1}, \ldots, x_{n}$, and $J$ is the Jacobian $\left(\partial x_{l} / \partial y_{k}\right)$. Since the Jacobian is nonsingular, $\operatorname{det}\left(\partial^{2} f / \partial y_{k} \partial y_{d}\right) \neq 0$ if and only if $\operatorname{det}\left(\partial^{2} f / \partial x_{i} \partial x_{j}\right) \neq 0$. The index of a nondegenerate critical point is the number of negative eigenvalues in the Hessian of $f$. By Sylvester's theorem from linear algebra, the index is independent of the coordinate systems. It may be interpreted as the number of independent directions along which $f$ is decreasing.

Example 17.14. Consider a torus in 3-space sitting on a plane as shown in Figure 17.13. Let $f(p)$ be the height of the point $p$ above the plane. Then as a function on the torus $f$ has four critical points $A, B, C$, and $D$, of indices 0 , 1,1 , and 2 respectively.

Figure 17.13
We outline below the proofs of the two main theorems of Morse theory. For details the reader is referred to Milnor [2, 83] or Bott and Mather [1, pp. 468-472].

Theorem 17.15. Let $f$ be a differentiable function on the manifold $M$, and $M_{\text {a }}$ the set $f^{-1}([-\infty, a])$. If $f^{-1}([a, b])$ is compact and contains no critical points, then $M_{a}$ has the same homotopy type as $M_{b}$.

Outline of Proor. Choose a Riemannian structure 〈, >on $M$. Then away from the critical points of $h$, the gradient $\nabla h$ of a differentiable function $f$ is defined: it is the unique vector field on $M$ such that for all vector fields $Y$ on $M$,

$$
\left\langle\nabla h_{p}, Y_{p}\right\rangle=d h_{d}\left(Y_{p}\right) .
$$

Let $X$ be the unit vector field $-\nabla f /\|\nabla f\|$. Because $f$ has no critical points on

Figure 17.14
$f^{-1}([a, b]), X$ is defined on $f^{-1}([a, b])$. As in vector calculus on $\mathbb{R}^{n}$ the gradient of a function points in the direction of the fastest increase, so $X$ points in the direction of the fastest decrease. Extend $X$ to a vector field on $M$. The fiow lines of $X$ give a deformation retraction of $M_{b}$ onto $M_{a}$ (Figure 17.14).

Theorem 17.16. Suppose $f^{-1}([a, b])$ is compact and contains precisely one critical point in its interior, which is nondegenerate and of index $k$. Then $M_{b}$ has the homotopy type of $M_{a} \cup e^{k}$.

To prove this theorem we need the following.

Morse lemma. If $p$ is a nondegenerate critical point of $f$ of index $k$, then there is a coordinate system $x_{1}, \ldots, x_{n}$ near $p$ such that

$$
f=f(p)-x_{1}^{2}-\cdots-x_{k}^{2}+x_{k+1}^{2}+\cdots+x_{n}^{2}
$$

The Morse lemma may be proved by the method used to diagonalize quadratic forms (see Milnor [2, p. 6]).

OUtLINE OF A PROOF OF THEOREM 17.16. Let $c=f(p)$ be the critical value and $\varepsilon$ a small positive number. By Theorem 17.15, $M_{b}$ has the homotopy type of $M_{c+e}$, and $M_{a}$ that of $M_{c-\varepsilon}$; so it suffices to show that $M_{c+z}$ has the homotopy type of $M_{c} \cup e^{k}$.

Figure 17.15

On a neighborhood $U$ of $p$ where the Morse lemma holds,

$$
\begin{aligned}
& M_{c+\varepsilon} \cap U=\left\{-x_{1}^{2}-\cdots-x_{k}^{2}+x_{k+1}^{2}+\cdots+x_{n}^{2} \leq \varepsilon\right\} \\
& M_{c-\varepsilon} \cap U=\left\{-x_{1}^{2}-\cdots-x_{k}^{2}+x_{k+1}+\cdots+x_{n}^{2} \leq-\varepsilon\right\}
\end{aligned}
$$

These regions are illustrated in Figure 17.15 for $k=1$ and $n=2$. The set $M_{c+a}$ is the shaded portion. (We choose $\varepsilon$ small enough so that $U$ meets the level sets $f^{-1}(c+\varepsilon)$ and $f^{-1}(c-\varepsilon)$.)

Let $C$ be the subset of $U$ defined by

$$
C=\left\{f \leq c+\varepsilon, x_{1}^{2}+\cdots+x_{k}^{2} \leq \delta\right\}
$$

where $\delta$ is a small positive number, say smaller than $\varepsilon^{2}$. Note that $C$ is homotopically equivalent to the cell $e^{k}$. Set $B=\overline{M_{c+e}-C}$. $B$ is the shaded region in the picture in Figure 17.16. From the picture it is plausible that $B$ can be contracted onto $M_{c-}$ by moving along the vector field $-\nabla f$. Since $M_{c+g}$ is obtained from $B$ by attaching $C$, up to homotopy

Figure 17.16
A smooth real-valued function on a manifold all of whose critical points are nondegenerate is called a Morse function. It follows from the two preceding theorems that there is a very close relation between the topology of a manifold and the critical points' of a Morse function. We next show that there are many Morse functions on any manifold: Our proof is taken from Guillemin and Pollack [1, pp. 43-45].

Lemma 17.17. Let $U$ be an open subset of $\mathbf{R}^{n}$ and $f$ any smooth real-valued function on $U$. Then for almost all $a=\left(a_{1}, \ldots, a_{n}\right)$ in $\mathbf{R}^{n}$, the function $f_{d}(x)=$ $f(x)+a_{1} x_{1}+\cdots+a_{n} x_{n}$ is a Morse function.

Proof. Recall that we denote the Jacobian matrix of a function $h$ by $D(h)$. Define $g(x)=\left(\partial f / \partial x_{1}, \ldots, \partial f / \partial x_{n}\right)$. Note that the Hessian of $f$ is precisely the

Jacobian of $g$, and $x$ is a nondegenerate critical point of $f$ if and only if $g(x)=0$ and $D(g)(x)$ is nonsingular. Let $g_{a}(x)=\left(\partial f_{\Omega} / \partial x_{1}, \ldots, \partial f_{a} / \partial x_{n}\right)$. Then $g_{\alpha}(x)=g(x)+a$ and $D\left(g_{a}\right)=D(g)$. In this setup $x$ is a critical point of $f_{a}$ if and only if $g(x)=-a$; it is nondegenerate if and only if in addition $D(g)(x)$ is nonsingular, i.e., $a$ is a regular value of $g$. By Sard's theorem almost all $a$ in $\mathbf{R}^{n}$ are regular values of $g$. For any such $a$, the function $f_{a}$ will be a Morse function on $U$.

Proposition 17.18. Let $M$ be a manifold of dimension $n$ in $\mathbf{R}^{\prime}$. For almost all $a=\left(a_{1}, \ldots, a_{r}\right)$ in $\mathbb{R}$, the function $f(x)=a_{1} x_{1}+\cdots+a_{r} x_{r}$ is a Morse function on $M$.

Proof. Let $x_{1}, \ldots, x_{r}$ be the coordinate functions on $\mathbb{R}^{r}$. Every point $x$ in $M$ has a neighborhood $U$ in $M$ on which some $n$ of $x_{1}, \ldots, x_{r}$ form a coordinate system. (Proof: Since $T_{x} M \rightarrow T_{x} \mathbb{R}^{r}$ is injective, $T_{x}^{*} \mathbb{R}^{r} \rightarrow T_{x}^{*} M$ is surjective, so $d x_{1}, \ldots, d x_{r}$ restrict to a spanning set in the cotangent space $T_{x}^{*} M$. If $d x_{i_{1}}, \ldots, d x_{i_{n}}$ is a basis for $T_{x}^{*} M$, then $x_{i_{1}}, \ldots, x_{i_{q}}$ is a set of local coordinates around $x$.) Because a manifold is by definition second countable, $M$ can be covered by a countable number of such open sets, $M=\bigcup_{i=1}^{\infty} U_{i}$. Suppose $x_{1}, \ldots, x_{n}$ form a local coordinate system on $U_{1}$. Fix ( $a_{n+1}, \ldots a_{n}$ ) and define $f(x)=a_{n+1} x_{n+1}+\cdots+a_{r} x_{r}$ on $U_{i}$. By Lemma 17.17, for almost all $\left(a_{1}, \ldots, a_{n}\right)$ the function $f(x)+a_{1} x_{1}+\cdots+a_{n} x_{n}$ is a Morse function on $U_{1}$. It follows that for almost all $a=\left(a_{1}, \ldots, a_{r}\right)$ in $\mathbf{R}$, the function $f_{d}(x)=a_{1} x_{1}+\cdots+a_{r} x_{r}$ is a Morse function on $U_{i}$. Let

$$
A_{i}=\left\{a \in \mathbb{R} \mid f_{\alpha}(x) \text { is not a Morse function on } U_{i}\right\} \text {. }
$$

If $a \in \mathbf{R}^{\prime}-\bigcup_{i=1}^{\infty}, A_{i}$, then $f_{d}(x)$ is a Morse function on $M$. Since $\bigcup_{i=1}^{\infty} A_{i}$ has measure zero, the proposition is proved.

Theorem 17.19. Every compact manifold $M$ has the homotopy type of a finite CW complex.

Proof. By Whitney's embedding theorem (see de Rham [1, p. 12]), we may assume that $M$ is a submanifold of some Euclidean space. Let $f$ be a Morse function on $M$ (the existence of $f$ is guaranteed by Proposition 17.18). By the Morse lemma, the critical points of $f$ are isolated. Since $M$ is compact, $f$ can have only finitely many critical points on $M$. Furthermore, for any real number $a$, the set $M_{n}=f^{-1}([-\infty, a])$ is compact, as it is a closed subset of a compact set. Let $p_{1}, \ldots, p_{r}$ be the critical points of index 0 . By the two main theorems of Morse theory (Theorems 17.15 and 17.16), up to homotopy $M$ is constructed from $p_{1}, \ldots, p_{r}$ by attaching cells, a cell of dimension $k$ for each critical point of index $\boldsymbol{k}>0$. Hence $M$ has the homotopy type of a finite CW complex.

## The Relation between Homotopy and Homology

The relation between the homotopy and the homology functors is a very subtle one. There is of course a natural homomorphism

$$
i: \pi_{d}(X) \rightarrow H_{d}(X)
$$

defined as follows: fix a generator $u$ for $H_{f}(S)$ and send $[f]$ in $\pi_{d}(X)$ to $f_{*}(u)$. In general $i$ is neither injective nor surjective. We have seen that $H_{q}$ is relatively computable. On the other hand, $\pi_{8}$ is not; there is no analogue of the Mayer-Vietoris principle for $\pi_{q}$. For this reason, the following theorems are a cornerstone of homotopy theory.

Theorem 17.20. Let $X$ be a path-connected space. Then $H_{1}(X)$ is the Abelianization of $\pi_{1}(X)$, i.e., if $\left[\pi_{1}(X), \pi_{1}(X)\right]$ is the commutator subgroup of $\pi_{1}(X)$, then $H_{1}(X)=\pi_{1}(X) /\left[\pi_{1}(X), \pi_{1}(X)\right]$.

We will assume this theorem as known. Its proof may be found in, for instance, Greenberg [1, p. 48]. The higher-dimensional analogue is

Theorem 17.21 (Hurewicz Isomorphism Theorem). Let $X$ be a simply connected path-connected CW complex. Then the first nontrivial homotopy and homology occur in the same dimension and are equal, i.e., given a positive integer $n \geq 2$, if $\pi_{d}(X)=0$ for $\downarrow \leq q^{\prime}<n$, then $H_{d}(X)=0$ for $1 \leq q<n$ and $H_{n}(X)=\pi_{n}(X)$.

Proof. To start the induction, consider the case $n=2$. The $E^{2}$ term of the homology spectral sequence of the path fibration

is

Thus

$$
\begin{array}{rlrl}
H_{2}(X) & =H_{1}(\Omega X) \quad & \quad \text { because } P X \text { has no homology } \\
& =\pi_{1}(\Omega X) & & \text { because } \pi_{1}(\Omega X)=\pi_{2}(X) \text { is Abelian } \\
& =\pi_{2}(X) . &
\end{array}
$$

Now let $n$ be any positive integer greater than 2. By the induction hypothesis applied to $\Omega X$,

$$
H_{q}(\Omega X)=0 \text { for } q<n-1
$$

and

$$
H_{n-1}(\Omega X)=\pi_{n-1}(\Omega X)=\pi_{n}(X) .
$$

The $E_{2}$ term of the homology spectral sequence of the path fibration is

Since $P X$ has trivial homology,

$$
H_{q}(X)=H_{q-1}(\Omega X)=0 \text { for } 1 \leq q<n
$$

and

$$
H_{n}(X)=H_{n-1}(\Omega X)=\pi_{n}(X) .
$$

Remark 17.21.1. A careful reader should have noticed that there is a sleight of hand in this deceptively simple proof: because we developed the Leray spectral sequence for spaces with a good cover (Theorem 15.11 and its homology analogue), to be strictly correct, we must show that both $X$ and $\Omega X$ have good covers. By (17.13), the $C W$ complex $X$ has a good cover. Next we quote the theorem of Milnor that the loop space of a $C W$ complex is again a $C W$ complex (Milnor [1, Cor. 3, p. 276]). So, at least up to homotopy, $\Omega X$ also has a good cover.

Actually the Hurewicz theorem is true for any path-connected topological space. This is a consequence of the $C W$-approximation theorem which, in the form that we need, states that given any topological space $X$ there is a $C W$ complex $K$, unique up to homotopy, such that $X$ and $K$ have the same homotopy and homology groups (Whitehead [1, Ch. V, Section 3, p. 219]). In its more general form, the $C W$-approximation theorem implies that in homotopy theory every space may be assumed to be a $C W$ complex. In any case, in the Hurewicz isomorphism theorem, we may drop the requirement that $X$ be a $C W$ complex.

The spectral sequence proof of the Hurewicz isomorphism theorem is due to Serre [2, pp. 271-274]. Actually, Serre's approach is slightly different; by developing a spectral sequence which is valid in much greater generality than ours, Serre could bypass the question of the existence of a gqod cover on a topological space. Of course, a price has to be paid for this greater generality; one has to work much harder to establish Serre's spectral sequence.

As a first and very important example, consider $S^{n}$ again. It follows from the Hurewicz theorem and the homology of $S^{n}$ that the homotopy groups of $S^{n}$ in low dimensions are

$$
\pi_{q}\left(S^{n}\right)=0 \quad \text { for } q<n
$$

and

$$
\pi_{n}\left(S^{\prime \prime}\right)=\mathbb{Z}
$$

$\pi_{3}\left(S^{2}\right)$ and the Hopf Invariant
Now that we have computed $\pi_{q}\left(S^{n}\right)$ for $q \leq n$, the first nontrivial computation of the homotopy of a sphere is $\pi_{3}\left(S^{2}\right)$. This can be done using the homotopy exact sequence of the Hopf fibration, as follows.

Let $S^{3}$ be the unit sphere $\left\{\left(z_{0}, z_{1}\right)\left|\left|z_{0}\right|^{2}+\left|z_{1}\right|^{2}=1\right\}\right.$ in $C^{2}$. Define an equivalence relation on $S^{3}$ by

$$
\left(z_{0}, z_{1}\right) \sim\left(w_{0}, w_{1}\right) \text { if and only if }\left(z_{0}, z_{1}\right)=\left(\lambda w_{0}, \lambda w_{1}\right)
$$

for some complex number $\lambda$ of absolute value 1. The quotient $S^{3} / \sim$ is the complex projective space $\mathbb{C} P^{1}$ and the fibering

$$
\begin{aligned}
S^{1} \rightarrow & S^{\mathbf{3}} \\
& \downarrow \\
& \stackrel{S}{ }^{2}=C P^{1}
\end{aligned}
$$

is the Hopf fibration. From the exact homotopy sequence

$$
\cdots \rightarrow \pi_{q}\left(S^{1}\right) \rightarrow \pi_{q}\left(S^{3}\right) \rightarrow \pi_{q}\left(S^{2}\right) \rightarrow \pi_{q-1}\left(S^{1}\right) \rightarrow \cdots
$$

and the fact that $\pi_{q}\left(S^{1}\right)=0$ for $q \geq 2$, we get $\pi_{q}\left(S^{3}\right)=\pi_{q}\left(S^{2}\right)$ for $q \geq 3$. In particular $\pi_{3}\left(S^{2}\right)=\mathbb{Z}$.

This homotopy group $\pi_{3}\left(S^{2}\right)$ was first computed by H. Hopf in 1931 using a linking number argument which associates to each homotopy class of maps from $S^{3}$ to $S^{2}$ an integer now called the Hopf invariant. We give here an account of the Hopf invariant first in the dual language of differential forms and then in terms of the linking number. Thus the setting for this section is the differentiable category.

Let $f: S^{3} \rightarrow S^{2}$ be a differentiable map and let $\alpha$ be a generator of $H_{D R}^{2}\left(S^{2}\right)$. Since $H_{D R}^{2}\left(S^{3}\right)=0$, there exists a 1 -form $\omega$ on $S^{3}$ such that
$f^{*} \alpha=d \omega$. As will be shown below, the expression

$$
H(f)=\int_{S^{3}} \omega \wedge d \omega
$$

is independent of the choice of $\omega$. We define $H(f)$ to be the Hopf invariant of $f$.

More generally the same procedure defines the Hopf invariant for any differentiable map $f: S^{2 n-1} \rightarrow S^{n}$. If $\alpha$ is a generator of $H_{D R}^{n}\left(S^{n}\right)$, then $f^{*} \alpha=d \omega$ for some $(n-1)$-form $\omega$ on $S^{2 n-1}$ and the Hopf invariant of $f$ is

$$
H(f)=\int_{S_{2}-1} \omega \wedge d \omega
$$

Proposition 17.22. (a) The definition of the Hopf invariant is independent of the choice of $\omega$.
(b) For odd $n$ the Hopf invariant is 0 .
(c) Homotopic maps have the same Hopf invariant.

Proor. (a) Let $\omega^{\prime}$ be another ( $n-1$-form on $S^{2 n-1}$ such that $f^{\star} \alpha=d \omega^{\prime}$. Then $0=d\left(\omega-\omega^{\prime}\right)$. Hence

$$
\begin{aligned}
\int_{S 2_{m}-1} \omega \wedge d \omega-\int_{S 2_{n-1}} \omega^{\prime} \wedge d \omega^{\prime} & =\int_{S_{2 n-1}}\left(\omega-\omega^{\prime}\right) \wedge d \omega \\
& =\int_{S_{2 n-1}} d\left(\left(\omega-\omega^{\prime}\right) \wedge \omega\right) \\
& =0 \text { by Stokes' theorem. }
\end{aligned}
$$

(b) Since $\omega$ is even-dimensional,

$$
\omega \wedge d \omega=\frac{1}{2} d(\omega \wedge \omega)
$$

By Stokes' theorem, $\int_{S_{2-1}-1} \omega \wedge d \omega=0$.
(c) By (b) we may assume $n$ even. Let $F: S^{2 \pi-1} \times I \rightarrow S^{n}$ be a homotopy between the two maps $f_{0}$ and $f_{1}$ from $S^{2 n-1}$ to $S^{n}$, where $I=[0,1]$. If $i_{0}$ is the inclusion

$$
i_{0}: S^{2 n-1} \rightarrow S_{0}=S^{2 n-1} \times\{0\} \subset S^{2 n-1} \times I
$$

and similarly for $i_{1}$, then

$$
\begin{aligned}
& F \circ i_{0}=f_{0}, \\
& F \circ i_{1}=f_{1} .
\end{aligned}
$$

Let $\alpha$ be a generator of $H_{D R}^{n}\left(S^{n}\right)$. Then $F^{*} \alpha=d \omega$ for some $(n-1)$-form $\omega$ on $S^{2 n-1} \times I$. Define $i \boldsymbol{i} \omega=\omega_{0}$ and $i_{i} \omega=\omega_{1}$. Then

$$
f f^{\prime} \alpha=d \omega_{0} \quad \text { and } \quad f_{1} \alpha=d \omega_{1}
$$

Note that

$$
\omega_{0} \wedge d \omega_{0}=i_{0}^{*}(\omega \wedge d \omega) .
$$

Hence,

$$
\begin{aligned}
H\left(f_{1}\right)-H\left(f_{0}\right) & =\int_{S_{2 n-1}} \omega_{1} \wedge d \omega_{1}-\int_{S_{2 n-1}} \omega_{0} \wedge d \omega_{0} \\
& =\int_{S_{2 n-1}} i_{1}^{*}(\omega \wedge d \omega)-\int_{S_{2 n-1}} i^{i}(\omega \wedge d \omega) \\
& =\int_{S_{1}} \omega \wedge d \omega-\int_{S_{0}} \omega \wedge d \omega \\
& =\int_{0\left(S_{2 n-1} \times I\right)} \omega \wedge d \omega \\
& =\int_{\left.S_{2 n-1} \times I\right)} d \omega \wedge d \omega \text { by Stokes' theolcm } \\
& =\int_{S_{2 n-1} \times I} F(\alpha \wedge \alpha) \\
& =0 \text { because } \alpha \wedge \alpha \in \Omega^{2 n}\left(S^{n}\right) .
\end{aligned}
$$

Since homotopy groups can be computed using only smooth maps (Proposition 17.8.1), it follows from Proposition 17.22(c) that the Hopf invariant gives a map

$$
H: \pi_{2 n-1}\left(S^{n}\right) \rightarrow \mathbb{R}
$$

We leave it as an exercise to the reader to prove that $H$ is in fact a homomorphism.

Actually the Hopf invariant is always an integer and is geometrically given by the linking number of the pre-images $A=f^{-1}(p)$ and $B=f^{-1}(q)$ of any two distinct regular values of $f$. In the classical case where $n=2$, these two submanifolds are two "circles" embedded in $S^{3}$. To fix the ideas. we will first explain the linking concept for this case.

The linking number of two disjoint oriented circles $A$ and $B$ in $S^{3}$, can be defined in several quite different, put equivalent ${ }_{2}$ ways.

## The Intersection-Theory Definition.

Choose a smooth surface $D$ in $S^{3}$ with boundary $A$ such that $D$ intersects $B$ transversally (Figure 17.17). Set the linking pumber to be

$$
\operatorname{link}(A, B)=\sum_{D \cap B} \pm 1 .!
$$

Here the sum is extended over the points in the intersection of $D$ with $B$ and the sign is given by the usual convention: at a point $x$ in $D \cap B$, the sign is

Figure 17.17
+1 or -1 according to whether the tangent space $T_{x} S^{3}$ has or does not have the direct sum orientation of $T_{x} D \oplus T_{x} B$ (Guillemia and Pollack [1, p. 108]).

It of course has to be shown that the linking number as defined is independent of the choice of $D$. This is a consequence of the discussion to follow.

## The Differential-Form Definition.

Choose disjoint open neighborhoods $W_{A}$ and $W_{B}$ of $A$ and $B$ and choose representatives $\eta_{A}$ and $\eta_{B}$ of the compact Poincare duals of $A$ and $B$ in $H_{c}^{2}\left(W_{A}\right)$ and $H_{c}^{2}\left(W_{B}\right)$. Because $H_{D x}^{2}\left(S^{3}\right)=0$, the extensions of $\eta_{A}$ and $\eta_{B}$ by zero to all of $S^{3}$, also denoted $\eta_{A}$ and $\eta_{B}$, are exact. Thus there are 1 -forms $\omega_{A}$ and $\omega_{g}$ on $S^{3}$ such that

$$
d \omega_{A}=\eta_{A} \quad \text { and } d \omega_{B}=\eta_{B}
$$

In terms of these forms one would expect, naively, that the dual to the intersection-theory definition is the expression

$$
\int_{s s} \omega_{A} \wedge \eta_{B}
$$

for if $A=\partial D$ and $\eta_{A}=d \omega_{A}$, then in some sense $D$ should correspond to $\omega_{A}$. So let this integral be the differential-form definition of the linking number of $A$ and $B$. We have to check that it is independent of all the choices involved. Let $\omega_{A}^{\prime}$ be some other form with $d \omega_{A}^{\prime}=\eta_{A}$. Then $\omega_{A}^{\prime}-\omega_{A}$ is closed. So

$$
\begin{aligned}
\int_{S_{3}}\left(\omega_{A}^{\prime}-\omega_{A}\right) \wedge_{\eta_{B}} & = \pm \int_{5_{3}} d\left[\left(\omega_{A}^{\prime}-\omega_{A}\right) \wedge \omega_{B}\right] \\
& =0
\end{aligned}
$$

On the other hand, if $\eta_{s}^{\prime}$ is another representative of $\left[\eta_{R}\right]$, then

$$
\eta_{s}-\eta_{s}^{\prime}=d \mu
$$

for some $\mu$ in $\Omega_{c}^{1}\left(W_{D}\right)$. Hence,

$$
\int_{53} \omega_{A} \wedge\left(\eta_{B}-\eta_{B}^{\prime}\right)=-\int_{s_{3}} d\left(\omega_{A} \wedge \mu\right)+\int_{s_{3}} \eta_{A} \wedge \mu
$$

Both terms on the right vanish: the first by Stokes' theorem, and the second because the supports of $\eta_{1}$ and $\mu$ are disjoint!

The differential-form definition is quite close to the Hopf invariant. To bring one into the other, we first choose disjoiat neighborhoods $U_{p}$ and $U_{\mathbf{s}}$ of the regular values $p$ and $q$ of $f$ and set $W_{A}=f^{-1}\left(U_{p}\right)$ and $W_{B}=f^{-1}\left(U_{\rho}\right)$ We next choose forms $\alpha_{p}$ and $\alpha_{q}$ in $\Omega_{t}^{2}\left(U_{\eta}\right)$ and $\Omega_{t}^{2}\left(U_{\phi}\right)$ representing the Poincart duals of $p$ and $q$ and set $\eta_{A}=f^{*} \alpha_{p}$, and $\eta_{s}=f^{*} \alpha_{\rho}$. According to the differential-form definition the linking number of $f^{-1}(p)=A$ and $f^{-1}(q)=B$ is then qiven by

$$
\int_{\infty} \omega_{\Lambda} \wedge \eta_{n}
$$

where $\omega_{1}$ is a form on $S^{3}$ with $d \omega_{A}=\eta_{1}$. On the other hand, as $\alpha_{p}$ geaerates $H_{D N}^{2}\left(S^{2}\right)$, the Hopf invariant is given by

$$
H(f)=\int_{31} \omega_{1} \wedge \eta_{1} .
$$

Because $\alpha_{p}$ and $\alpha_{q}$ are both representatives for the generator of $H_{D \mu}^{2}\left(S^{2}\right)$, there is a form $\beta$ in $\Omega^{2}\left(S^{2}\right)$ such that

$$
\alpha_{p}-\alpha_{q}=\Delta \beta .
$$

Hence,

$$
\begin{aligned}
\omega_{A} \wedge\left(\eta_{A}-\eta_{B}\right) & =\omega_{A} \wedge f^{*} d \beta \\
& =-d\left(\omega_{A} \wedge f^{*} \beta\right)+\left(d \omega_{A}\right) \wedge f^{*} \beta
\end{aligned}
$$

The last term on the right equals

$$
\eta_{A} \wedge f^{*} \beta=f^{*}\left(\alpha_{p} \wedge \beta\right) .
$$

But $\alpha, \mathcal{N}_{;} ; \beta \in \Omega^{3}\left(S^{2}\right)$ and hence vanishes! By Stokes' theorem it follows that

$$
\int_{33} \omega_{A} \wedge \eta_{B}=\int_{33} \omega_{A} \wedge \hat{\eta}_{A}=H(f),
$$

as was to be shown.
Finally we prove the compatibility of the two definitions of the linking number. This will then also explain why the Hopf invariant is always an integer.

To start off one needs certain plausible constructions of differential topology. The first of these is that a surface such as $D$, which has boundary $A$, can always be extended by a small ribbon difficomorphic to $A \times[0,1]$ More precisely, there exists an embedding

$$
\phi: A \times[-1,1] \hookrightarrow S^{3}
$$

such that $\phi$ maps $A \times[-1,0]$ diffeomorphically onto a closed neighborhood of $A=\delta D$ in $D$, with $A \times\{0\}$ going to $A$, and such that

$$
D_{1}=D \cup \phi(A \times[0,1])
$$

is still a smoothly embedded manifold with boundary. If we set

$$
D_{-1}=D-\phi(A \times(-1,0]),
$$

this construction exhibits $D$ in a nested sequence of submanifolds with boundary

$$
D_{1} \supset D \supset D_{-1}
$$

with the interior of $D_{1}-D_{-1}$ being diffeomorphic to $A \times(-1,1)$. A map $\phi$ of this type is often called a collar about $\partial D$, and the restriction of $\phi$ to $A \times(-1,1)$ an open collar about $\partial D$.

Using this parametrization we can clearly construct a smooth function $\chi_{A}$ on $D_{1}$ such that
(1) $\chi_{A} \equiv 0$ near $\partial D_{1}$, and
(2) $\chi_{A} \equiv 1$ on a neighborhood of $D_{-1}$ in $D_{1}$.

It follows that $d \chi_{A}$ is a 1 -form with compact support on the open collar $D_{1}^{\circ}-D_{-1}$, where $D_{1}^{\circ}$ is the interior of $D_{1}$. Furthermore, $d \chi_{A}$ represents the compact Poincaré dual of $A$ in $\Omega_{c}^{1}\left(D_{1}^{\circ}-D_{-1}\right)$.

Next we choose a neighborhood of $D_{1}$ in $S^{3}$, say $W$, small enough to admit a retraction

$$
r: W \rightarrow D_{1}
$$

(For $\varepsilon$ small enough an $\varepsilon$-neighborhood of $D_{1}$ relative to some Riemannian structure on $S^{3}$ will do.) Let $T$ be a tubular neighborhood of $D_{1}-\partial D_{1}$ in $W-\partial D_{1}$ diffeomorphic to the unit disk bundle in the normal bundle of $D_{1}-\partial D_{1}$ in $W-\partial D_{1}$ and let $\omega_{A}^{\circ}$ represent the Thom class of $T$ in $\Omega_{c v}^{1}(T)$. See Figure 17.18.

Figure 17.18

Now consider the 1 -form

$$
\omega_{A}=\left(r^{*} \chi_{A}\right) \omega_{A}^{\circ} .
$$

It has many virtues. First of all it has compact support in $W$ and so can be extended by zero to all of $S^{3}$. This comes about because $\omega_{A}^{\circ}$ has compact support normal to $D_{1}^{\circ}$ and $r^{*} \chi_{A}$ vanishes identically near $\partial D_{1}$. Secondly, we see that if we set

$$
\dot{W}_{A}=r^{-1}\left(D_{1}^{\circ}-D_{-1}\right),
$$

then $d \omega_{A} \in \Omega_{c}^{2}\left(W_{A}\right)$ and represents the compact Poincare dual of $A$ there.
We will use this $\omega_{A}$ in the integral $\int_{S_{3}} \omega_{A} \wedge \eta_{E}$ to complete the argument that

$$
\int_{S^{3}} \omega_{A} \wedge_{\eta_{B}}=\sum_{D \cap B} \pm 1
$$

First choose a small enough neighborhood $W_{B}$ of $B$, a small enough collar for $D$, and a small enough tubular neighborhood $T$ for $D_{i}^{\circ}$ so that (see Figure 17.19)

Figure 17.19
Once this is done $\omega_{A}$ will equal $\omega_{A}^{\circ}$ in the support of $\eta_{B}$ since on $r^{-1}\left(D_{-1}\right)$ the function $r^{*} \chi_{A}$ is identically 1. Therefore, our integral can be rewritten in the form

$$
\begin{equation*}
\int_{s z-0 D_{1}} \omega_{A}^{0} \wedge \eta_{k} \tag{*}
\end{equation*}
$$

But now $\omega_{A}^{\circ}$ represents the Poincare dual of $D_{1}^{\circ}$ in $\Omega^{1}\left(S^{3}-\partial D_{1}\right)$ and $\eta_{B}$ the compact Poincare dual of $B$ in $\Omega_{c}^{1}\left(S^{3}-\partial D_{1}\right)$. In Section 6 we discussed the relation between the Thom isomorphism, Poincaré duality, and the transversal intersections of closed oriented submanifolds. Although (6.24) and (6.31) were stated for the closed Poincare duals, the same discussion applies to the compact Poincare duals, provided the relevant submanifolds are compact. Hence the integral $\left(^{*}\right)$ just counts the transversal intersection number of $D_{1}$ with $B$. Thus

$$
\int_{S^{3}} \omega_{A} \wedge \eta_{B}=\sum_{D_{1} \cap B} \pm 1=\sum_{D \cap B} \pm 1
$$

the last being valid because the extension $D_{1}$ intersects $B$ no more often than $D$ did.

Remark. The arguments of this section of course extend to the higherdimensional examples. In particular the two definitions of the linking number make sense and are equivalent whenever $A$ and $B$ are compact oriented submanifolds of an oriented manifold $M$ satisfying the following conditions:
(1) $A$ and $B$ are disjoint;
(2) $\operatorname{dim} A+\operatorname{dim} B=\operatorname{dim} M-1$;
(3) both $A$ and $B$ are bounding in the sense that their fundamental classes are homologous to zero in $H_{*}(M)$.

Linking is therefore not a purely homological concept.
We cannot resist mentioning at this point that there is yet a third definition of the linking number of two disjoint oriented circles $A$ and $B$ in $S^{3}$.

The Degree Definition.
Remove a point $p$ from $S^{\mathbf{3}}$ not on $A$ or $B$ and identify $S^{\mathbf{3}}-\{p\}$ with $R^{\mathbf{3}}$. Let

$$
L: A \times B \rightarrow S^{2}
$$

be the map to the unit sphere in $\mathbf{R}^{\mathbf{3}}$ given by

$$
L(x, y)=\frac{x-y}{\|x-y\|}
$$

where || \| denotes the Euclidean length in $\mathbf{R}^{3}$. Give $A \times B$ the product orientation and $S^{\mathbf{2}}$ the standard orientation. Then

$$
\operatorname{link}(A, B)=\operatorname{deg} L .
$$

We close this section with two explicit computations of the Hopf invariant in the classical case, one using the differential-geometric and the other the intersection point of view. Just to be sure, if you will.

Example 17.23 (The Hopf invariant of the Hopf fibration). Let $S^{3}$ be the unit sphere in $\mathbb{C}^{2}$ and $f: S^{3} \rightarrow \mathbf{C} P^{1}$ the natural map

$$
f:\left(z_{0}, z_{1}\right) \rightarrow\left[z_{0}, z_{1}\right],
$$

where we write $\left[z_{0}, z_{1}\right]$ for the homogeneous coordinates on $C P^{1}$. If $C P^{1}$ is identified with the unit sphere $S^{2}$ in $R^{3}$, say via the stereographic projection, then the map $f: S^{3} \rightarrow S^{2}$ is the Hopf fibration. To compute its Hopf invariant, we proceed in five steps:
(a) Find a volume form $\sigma$ on the 2 -sphere.
(b) Write down a diffeomorphism $g: C P^{1} \leadsto S^{2}$.
(c) Pull the generator $\sigma$ of $H^{2}\left(S^{2}\right)$ via $g$ back to a generator $\alpha$ of $H^{2}\left(\mathbb{C} P^{1}\right)$.
(d) Pull $\alpha$ back to $S^{3}$ via $f$ and find a 1 -form $\omega$ such that $f^{*} \alpha=d \omega$ on $S^{3}$.
(e) Compute $\int_{s^{3}} \omega \wedge d \omega$.
(a) A Volume Form on the 2-Sphere.

Let $u_{1}, u_{2}$, and $u_{3}$ be the standard coordinates of $\mathbb{R}^{3}$. By Exercise 4.3.1 a generator of $H^{2}\left(S^{2}\right)$ is

$$
\sigma=\frac{1}{4 \pi}\left(u_{1} d u_{2} d u_{3}-u_{2} d u_{1} d u_{2}+u_{3} d u_{1} d u_{2}\right)
$$

Since (dr) $\sigma=(r / 4 \pi) d u_{1} d u_{2} d u_{3}$, which is the standard orientation on $\mathbb{R}^{3}$, the form $\sigma$ represents the positive generator on $S^{2}$ (see the discussion preceding Exercise 6.32).

Over the open set in $S^{2}$ where $u_{3} \neq 0$, the form $\sigma$ has a simpler expression. For if

$$
u_{1}^{2}+u_{2}^{2}+u_{3}^{2}=1
$$

then

$$
u_{1} d u_{1}+u_{2} d u_{2}+u_{3} d u_{3}=0,
$$

so that we can eliminate $d \mu_{3}$ from $\sigma$ to get

$$
\begin{equation*}
\sigma=\frac{1}{4 \pi} \frac{d u_{1} d u_{2}}{u_{3}} . \tag{17.23.1}
\end{equation*}
$$

(b) Stereographic Projection of $S^{2}$ onto $\underset{C P}{ }{ }^{1}$;

In the homogeneous coordinates $\left[z_{0}, z_{1}\right]$ on $C P^{1}$, the single point $\left[z_{0}, 0\right]$ is called the point at infinity. On the open set $z_{1} \neq 0$, we may"use. $z=z_{0} / z_{1}$ as the coordinate and identify the point $z=x+i y$ in $C P^{1}-\{[1,0]\}$ with the point $(x, y, 0)$ of the $\left(u_{1}, u_{2}\right)$-plane in $R^{3}$. Then the stereographic projection
from the north pole $(0,0,1)$ maps $S^{2}$ onto $C P^{1}$, sending the north pole to the point at infinity (Figure 17.20 ). To find the inverse map $g: C P^{1} \rightarrow S^{2}$, note that the line through $(0,0,1)$ and $(x, y, 0)$ has parametric equation $(0,0,1)+t(x, y,-1)$, which intersects the unit sphere when

$$
t^{2} x^{2}+t^{2} y^{2}+(1-t)^{2}=1
$$

that is,

$$
t=0 \quad \text { or } \quad \frac{2}{1+x^{2}+y^{2}}
$$

Hence the inverse map $g: C P^{1} \rightarrow S^{2} \subset \mathbf{R}^{3}$ is given by

$$
\begin{equation*}
z=x+i y \mapsto\left(\frac{2 x}{1+x^{2}+y^{2}}, \frac{2 y}{1+x^{2}+y^{2}}, \frac{-1+x^{2}+y^{2}}{1+x^{2}+y^{2}}\right) \tag{17.23.2}
\end{equation*}
$$

Figure 17.20
(c) The Generator of $\mathrm{H}^{2}\left(\mathrm{CP} P^{1}\right)$.

By pulling the generator $\sigma$ in $H^{2}\left(S^{2}\right)$ back to $C P^{1}$ we obtain a generator $g^{*} \sigma$ in $H^{2}\left(C P^{\mathbf{l}}\right)$. It follows from (17.23.1) and (17.23.2) that in the appropriate coordinate patch,

$$
g^{*} \sigma=\frac{1}{4 \pi} \frac{d u_{1} d u_{2}}{u_{3}},
$$

where

$$
u_{1}=\frac{2 x}{1+x^{2}+y^{2}}, \quad u_{2}=\frac{2 y}{1+x^{2}+y^{2}}, \quad \text { and } u_{3}=\frac{-1+x^{2}+y^{2}}{1+x^{2}+y^{2}} .
$$

In terms of $z=x+i y$, the form $g^{*} \sigma$ can be written as

$$
g^{*} \sigma=-\frac{1}{\pi} \frac{d x d y}{\left(1+x^{2}+y^{2}\right)^{2}}=-\frac{i}{2 \pi} \frac{d z d \bar{z}}{\left(1+|z|^{2}\right)^{2}} .
$$

By convention the standard orientation on $C P^{1}$ is given locally by $d x d y$. Therefore the positive generator in $H^{2}\left(C P^{1}\right)$ is

$$
\alpha=-g^{\star} \sigma=\frac{i}{2 \pi} \frac{d z d \bar{z}}{\left(1+|z|^{2}\right)^{2}} .
$$

Since $z=z_{0} / z_{1}$, in terms of the homogeneous coordinates,

$$
\begin{equation*}
\alpha=\frac{i}{2 \pi} \frac{\left(z_{1} d z_{0}-z_{0} d z_{1}\right)\left(\bar{z}_{1} d \bar{z}_{0}-\bar{z}_{0} d \bar{z}_{1}\right)}{\left(\left|z_{0}\right|^{2}+\left|z_{1}\right|^{2}\right)^{2}} . \tag{17.23.3}
\end{equation*}
$$

Remark. If $S^{2}$ and $\mathbb{C} P^{1}$ are given their respective standard orientations, then the stereographic projection from $S^{2}$ to $\mathbb{C} P^{1}$ is orientation-reversing.
(d) Finding an $\omega$ such that $f^{*} \alpha=d \omega$ on $S^{3}$;

Let $z_{0}=x_{1}+i x_{2}$ and $z_{1}=x_{3}+i x_{4}$ be the coordinates on $C^{2}$. Then the unit 3 -sphere $S^{3}$ is defined by

$$
\left|z_{0}\right|^{2}+\left|z_{1}\right|^{2}=x_{1}^{2}+x_{2}^{2}+x_{3}^{2}+x_{4}^{2}=1 .
$$

Hence $\sum_{i=1}^{4} x_{i} d x_{i}=0$ on $S^{3}$. By a straightforward computation, replacing $z_{0}$ and $z_{1}$ in (17.23.3) by the $x_{i}$ 's, we find

$$
f^{*} \alpha=\frac{1}{\pi}\left(d x_{1} d x_{2}+d x_{3} d x_{4}\right)=\frac{1}{\pi} d\left(x_{1} d x_{2}+x_{3} d x_{4}\right) .
$$

Therefore, we may take $\omega$ to be

$$
\omega=\frac{1}{\pi}\left(x_{1} d x_{2}+x_{3} d x_{4}\right) .
$$

(e) Computing the Integral.

The Hopf invariant of the Hopf fibration is :

$$
\begin{aligned}
H(f) & =\int_{S^{3}} \omega \wedge d \omega \\
& =\frac{1}{\pi^{2}} \int_{s^{3}} x_{1} d x_{2} d x_{3} d x_{4}+x_{3} d x_{1} d x_{2} d x_{4} \\
& =\frac{2}{\pi^{2}} \int_{S^{3}} x_{1} d x_{2} d x_{3} d x_{4} \text { by symmetry }
\end{aligned}
$$

## Using spherical coordinates,

$$
\begin{aligned}
& x_{1}=\sin \xi \sin \phi \cos \theta, \\
& x_{2}=\sin \xi \sin \phi \sin \theta, \\
& x_{3}=\sin \xi \cos \phi, \\
& x_{4}=\cos \xi,
\end{aligned}
$$

where $0 \leq \xi \leq \pi, 0 \leq \phi \leq \pi$, and $0 \leq \theta \leq 2 \pi$, the integral becomes

$$
\begin{aligned}
\int_{S_{3}} x_{1} d x_{2} d x_{3} d x_{4} & =\int_{0}^{x} \int_{0}^{\pi} \int_{0}^{2 \pi} \sin ^{4} \xi \sin ^{3} \phi \cos ^{2} \theta d \theta d \phi d \xi \\
& =\pi^{2} / 2 .
\end{aligned}
$$

Therefore, the Hopf invariant of $f$ is 1 .
This Hopf invariant may also be found geometrically, for by identifying $S^{3}$ - \{north pole\} with $\mathbf{R}^{3}$ via the stereographic projection, it is possible to visualize the fibers of the Hopf fibration

$$
\begin{aligned}
S^{1} \rightarrow & S^{3} \\
& \vdots \\
S^{2} & =C P^{1}
\end{aligned}
$$

and to compute the linking number of two fibers. We let $z_{0}=x_{1}+i x_{2}$, $z_{1}=x_{3}+i x_{4}$. Then the stereographic projection

$$
p: S^{3}-\{(0,0,0,1)\} \rightarrow R^{3}=\left\{x_{4}=0\right\}
$$

is given by

$$
\left(x_{1}, x_{2}, x_{3}, x_{4}\right) \mapsto\left(\frac{x_{1}}{1-x_{4}}, \frac{x_{2}}{1-x_{4}}, \frac{x_{3}}{1-x_{4}}\right)
$$

This we see as follows. The line through the north pole $(0,0,0,1)$ and the point ( $x_{1}, x_{2}, x_{3}, x_{4}$ ) has parametric equation $(0,0,0,1)+d\left(x_{1}, x_{2}, x_{3}\right.$, $\left.x_{4}-1\right)$. It intersects $R^{3}=\left\{x_{4}=0\right\}$ at $t=1 /\left(1-x_{4}\right)$, so the intersection point is

$$
\left(\frac{x_{1}}{1-x_{4}}, \frac{x_{2}}{1-x_{4}}, \frac{x_{3}}{x-x_{4}}, 0\right) .
$$

See Figure 17.21.
Note that the fiber $S_{\infty}$ of the Hopf fibration over $[1,0] \in C P^{1}$ is $\left\{\left(z_{0}\right.\right.$, $\left.0) \in C^{2}| | z_{0} \mid=1\right\}$ and the fiber $S_{0}$ over $[0,1]$ is $\left\{(0,0, \cos \theta, \sin \theta) \in R^{4}\right.$, $0 \leq \theta \leq 2 \pi\}$, both oriented counterclockwise in their planes. So via the stereographic projection $S_{\infty}$ corresponds to the unit circle in the ( $x_{1}$, $x_{2}$ )-plane while $S_{0}$ corresponds to $\{(0,0, \cos \theta / 1-\sin \theta), 0 \leq \theta \leq 2 \pi\}$, which is the $x_{3}$-axis with its usual orientation. Therefore the linking number

Figure 17.21
of $S_{\infty}$ and $S_{0}$ is 1 . By the geometric interpretation of the Hopf invariant as a linking number, the Hopf invariant of the Hopf fibration is 1.

Exercise 17.24. (a) Given an integer $q$, show that for $n \geq q+2$, the natural inclusion $O(n) \subset \dot{O}(n+1)$ induces an isomorphism $\pi(O(n)) \simeq \pi(O(n+1))$, For $n$ suficiently large, the homotopy group $\pi(O(n))$ is therefore independent of $n$ and we can write $\pi(O)$. This is the $q$-th stable homotopy group of the orthogonal group.
(b) Given integers $k$ and $q$, show that for $n \geq k+q+2$,

$$
\pi_{d}(O(n) / O(n-k))=0
$$

(c) Similarly, use the fiber bundle of $S^{2 n+1}=U(n+1) V U(n)$ to show that for $2 n \geq q+1$, the inclusion $U(n) \subset U(n+1)$ induces an isomorphism

$$
\pi_{d}(U(n)) \simeq \pi_{d}(U(n+1))
$$

Deduce that for $n \geq(2 k+q+1) / 2$,

$$
\pi_{d}(U(n) / U(n-k))=0
$$

## §18 Applications to Homotopy Theory

The Leray spectral sequence is basically a tool for computing the homology or cohomology of a fibration. However, since by the Hurewicz isomorphism theorem, the first nontrivial homology of the Eilenberg-MacLane space $K\left(\pi_{d}(X), n\right)$ is $\pi_{d}(X)$, if one can fit the Eilenberg-MacLane spaces $K\left(\pi_{d}(X), n\right)$ into a fibering it may be possible to apply the spectral sequence to compute the homotopy groups. Such fiberings are provided by the Poutnikov approximation and the Whitehead tower, two twisted products of Eilenber:-

MacLane spaces which in some way approximate a given spaw in homotopy. As examples of how this works, we compute in this section $\pi_{4}\left(S^{3}\right)$ and $\pi_{s}\left(S^{3}\right)$.

## Eilenberg-MacLane Spaces

Let $A$ be a group. A path-connected space $Y$ is an Eilenberg-MacLane space $K(A, n)$ if

$$
\pi_{Q}(Y)=\left\{\begin{array}{l}
A^{\prime} . \text { in dimension } n \\
0 \\
0 \text { otherwise } .
\end{array}\right.
$$

(We do not consider $\pi_{0}$ unless otherwise indicated.) For any group $A$ and any integer $n \geq 1$ (with the obvious restriction that $A$ be Abelian if $n>1$ ), it can be shown that in the category of $C W$ complexes such a space exists and is unique up to homotopy equivalence (Spanier [1, Chap. 8, Sec. 1, Cor. 5, p. 426] and Mosher and Tangora [1, Cor. 2, p. 3]). So provided we consider only $C W$ complexes, the symbol $K(A, n)$ is unambiguous.

Example 18.1. (a) Since $\pi: \mathbb{R}^{1} \rightarrow S^{1}$ given by

$$
\pi(x)=e^{2 \pi i x}
$$

is a covering soace, $\pi_{q}\left(S^{1}\right)=\pi_{q}\left(\mathbb{R}^{1}\right)=0$ for $q \geq 2$ by (17.5). Therefore the circle is a $K(\mathbb{Z}, 1)$.
(b) If $F$ is a free group, then $K(F, 1)$ is a bouquet of circles, one for each generator (Figure 18.1).

Figure 18.1
(c) The fundamental group of a Riemann surface $S$ of genus $g \geq 1$ (Figure 18.2) is a group $\pi$ with generators $a_{1}, b_{1}, \ldots, a_{e}, b_{f}$ and a single relation

$$
a_{1} b_{1} a_{1}^{-1} b_{1}^{-1} \cdots a_{\theta} b_{\theta} a_{\theta}^{-1} b_{\theta}^{-1}=1
$$

By the uniformization theorem of complex function theory the 'universal cover of a Riemann surface of genus $g \geq 1$ is contractible. Hence the Rie.mann surface $S$ is the Eilenberg-MacLane space $K(\dot{\pi}, 1)$.'

Figure 18.2
(d) By Proposition 17.2, we see that $\Omega K(A, n)=K(A, n-1)$.
(e) The Eilenberg-MacLane space $K(\mathbb{Z}, n)$ may be constructed from the sphere $S^{n}$ by killing all $\pi_{d}\left(S^{n}\right)$ for $q>n$. The procedure for killing homotopy groups is discussed in the section on Postnikov approximation.
(f) By (17.1.a) if $A$ and $B$ are two groups, then.

$$
K(A, n) \times K(B, n)=K(A \times B, n) .
$$

## The Telescoping Construction

In this section we give' a technique for constructing certain EilenbergMacLane spaces, called the telescoping construction. It is best ilhustrated with examples.

Example. 18.2 (The infinite. real projective space). The real projective space $R P^{n}$ is defined as the quotient of the sphére $S^{m}$ under the equivalence relation which identifies the antipodal points of $S^{n}$. There is a natural sequence of inclusions

$$
\text { \{point \} } \hookrightarrow \cdots \stackrel{i}{\hookrightarrow} R P^{n}{ }_{\hookrightarrow}^{i} R P^{n+1} \hookrightarrow \cdots \cdot
$$

We define the infinite real projective space $R P^{\infty}$ by gluing together via the natural inclusions all the finite real projective spaces

$$
R P^{\infty}=\coprod_{. n} R P^{n} \times I /(x, 1) \sim(i(x), 0) .
$$

Pictorially $R P^{\infty}$. looks like an infinite telescope (Figure 18.3). $\therefore \quad . \quad=14$
Since $S^{n} \rightarrow \mathbb{R} P^{n}$ is a double cover, by (17.5) $\pi_{d}\left(R P^{n}\right)=\pi_{d}\left(S^{n}\right)=0$ for $1<q<n$. We now show that $\mathbb{R} P^{\infty}$ has no higher homotopy, i.e., $\pi_{q}\left(\mathbb{R} P^{\infty}\right)=0$ for $q>1$. Take $\pi_{15}\left(R P^{\infty}\right)$ for example. Suppose $f: S^{15} \rightarrow R P^{\infty}$ represents an element of $\pi_{15}\left(R P^{\infty}\right)$. Since the image $f\left(S^{15}\right)$ is compact, it must lie in a finite union of the $R P^{n} \times I$ 's above. We can slide $f\left(S^{15}\right)$ into a high RP $\times 1$. If $n>15$, then $f\left(S^{15}\right)$ will be contractible. Therefore $\pi_{15}\left(R P^{\infty}\right)=0$. Thus by sliding the image of a sphere into a high enough projective space, we see that this telescope kills all higher homotopy groupe.

Figure 18.3
Applying the telescoping construction to the sequence of spheres

$$
\text { \{point\} } \& \cdots \frac{1}{4} S^{n} \frac{1}{4} S^{n+1} \hookrightarrow \cdots
$$

we obtain the infinite sphere

$$
S^{\infty}=\coprod_{n} S^{\infty} \times I /(x, 1) \sim(H(x), 0) .
$$

It is a double cover of Rpm. By the same reasoning as above, $S^{\infty}$ has no homotopy in any dimension. Therefore $\pi_{1}\left(\mathbf{R} P^{\infty}\right)=\mathbb{Z}_{2}$. This proves that RPo is a $K\left(Z_{2}, 1\right)$.

Example 18.3. (The infinite complex projective space). Applying the telescoping construction to the requences

$$
\begin{gathered}
\cdots \subset S^{2 n+1} \subset S^{2 n+3} \subset \cdots \\
S^{1} \downarrow \\
\cdots \subset C P^{n} \subset C P^{n+1} \subset \cdots
\end{gathered}
$$

we obtain the fibering

$$
\begin{align*}
S^{1} \rightarrow & S^{\infty} \\
& \downarrow  \tag{18.3.1}\\
& C P^{\infty}
\end{align*}
$$

where $C P^{\infty}$ is gotten by gluing together the CP's as in the previous example. Since $S^{\infty}$ has no homotopy in any dimension, it follows from the homotopy sequence of the fibering that

$$
\pi_{k}\left(C^{\infty}\right)= \begin{cases}Z & \text { when } k=2 \\ 0 & \text { otherwise. }\end{cases}
$$

Therefore $\mathbf{C} P^{\infty}$ is a $K(\mathbf{Z}, 2)$.
Exercise 18.4. By the Hurewicz isomorphism theorem $H_{k}\left(S^{\infty}\right)=0$ except in dimension 0. Apply the spectral sequence of the fibering (18.3.1) to show
that the cohomology ring of $C P^{\infty}$ is a polynomial algebra with a generator in dimension 2:

$$
H^{*}\left(C P^{\infty}\right)=\mathbb{Z}[x], \quad \operatorname{dim} x=2 .
$$

Example 18.5 (Lens spaces). Let $S^{2 n+1}$ be the unit sphere in $C^{n+1}$. Since $S^{1}$ acts freely on $S^{2 n+1}$, so does any subgroup of $S^{1}$. For example, $Z_{s}$ acts on $S^{2 n+1}$ by

$$
e^{2 \pi \alpha / 5}:\left(z_{0}, \ldots, z_{n}\right) \mapsto\left(e^{2 \pi / / 5} z_{0}, \ldots, e^{2 \pi / 1 / z_{n}}\right)
$$

The quotient space of $S^{2 n+1}$ by the action of $Z_{s}$ is the Lens space $L(m, 5)$. Applying the telescoping construction

$$
\begin{gathered}
S^{1} \subset \cdots \subset S^{2 n+1} \subset S^{2 n+3} \quad \subset \cdots \\
\mathbf{Z}_{5} \downarrow \\
4(0,5) \subset \cdots \subset L(n, 5) \subset L(n+1,5) \subset \cdots
\end{gathered}
$$

we obtain a five-sheeted covering

$$
\begin{gathered}
\mathbf{Z}_{\mathbf{s}} \rightarrow S^{\infty} \\
t \\
\\
\quad(\infty, 5)
\end{gathered}
$$

Hence

$$
\pi_{k}(L(\infty, 5))= \begin{cases}Z_{3} & \text { if } k=1 \\ 0 & \text { if } k>1\end{cases}
$$

So the infinite Lens space $L(\infty, 5)$ is a $K\left(Z_{5}, 1\right)$. In exactly the same manner we can construct $L(\infty, q)=K\left(Z_{q}, 1\right)$ for any positive integer $q$.

Remark 18.5.1. The Lens space $L(n, 2)$ is the real projective space $R P^{2 m+1}$, and the infinite Lens space $L(\infty, 2)$ is $R P^{\infty}$.

Next we shall compute the cohomology of a Lens space, say $L(n, 5)$. Since the Lens space $L(n, 5)$ is not simply connected, the defining fibration $\mathbf{Z}_{s} \rightarrow S^{2 n+1} \rightarrow L(n, 5)$ is of little use in the computation of the cobomology. Instead, note that the free action of $S^{1}$ on $S^{2 n+1}$ descends to an action on $L(n, 5)$ :

$$
\left(z_{0}, \ldots, z_{n}\right) \mapsto\left(\lambda z_{0}, \ldots, \lambda z_{n}\right) \quad \lambda \in S^{1} \subset C^{*},
$$

with quotient $C P^{\prime \prime}$, so that there is a fiber bundle

$$
\begin{array}{r}
s^{1} \rightarrow L(n, 5) \\
\pi_{L} \downarrow \\
C P^{n} .
\end{array}
$$

The $E_{2}$ term of this fiber bundle is

To decide what the differential $d_{2}$ is, we compare with the spectral sequence of the fiber bundle $S^{1} \rightarrow S^{2 n+1} \xrightarrow{x_{3}} C^{P^{n}}$. The bundle map $\rho$ : $S^{2 n+1} \rightarrow L(n, 5)$ over $\mathbb{C} P^{n}$ induces a chain map on the double complexes

$$
\rho^{*}: C^{*}\left(\pi_{\mathcal{L}}^{-1} \mathfrak{U}, \Omega^{*}\right) \rightarrow C^{*}\left(\pi_{\boldsymbol{s}}^{-1} \mathfrak{U}, \Omega^{*}\right)
$$

where $\mathbb{U}$ is a good cover of $C P^{n}$. Let $a_{L}$ and $a_{s}$ be the generators of $E_{2}^{0,1}$ for these two complexes, and $x$ a generator of $H^{*}\left(\mathbb{C} P^{\prime \prime}\right)$. Because $\rho$ is a map of degree $5, \rho^{*} a_{L}=5 a_{s}$. Hence,

$$
\rho^{*}\left(d_{2} a_{L}\right)=d_{2} \rho^{*} a_{L}=d_{2} 5 a_{S}=5 x
$$

So $d_{2} a_{L}=5 x$ in (18.5.2). The cohomology of the Lens space $L(n, 5)$ is therefore

$$
H^{*}(L(n, 5))= \begin{cases}\mathbb{Z} & \text { in dimension } 0 \\ \mathbb{Z}_{5} & \text { in dimensions } 2,4, \ldots, 2 n \\ \mathbb{Z} & \text { in dimension } 2 n+1 \\ 0 & \text { otherwise }\end{cases}
$$

Remark 18.5.3. Another way of determining the differential in (18.5.2) is to compute $H^{2}(L(n, 5))$ first by the universal coefficient theorem (15.14). Since $\pi_{1}(L(n, 5))=\mathbf{Z}_{5}, H_{1}(L(n, 5))=\mathbf{Z}_{5}$ and $H^{2}=\mathbf{Z}_{5} \oplus$ free part. Therefore $d_{2} a$ must be $5 x$ and $H^{2}=\mathbf{Z}_{5}$.

In exactly the same way we see that the cohomology of the Lens space $L(n, q)$ is

$$
H^{*}(L(n, q))= \begin{cases}\mathbb{Z} & \text { in dimension } 0  \tag{18.6}\\ \mathbb{Z}_{q} & \text { in dimensions } 2,4, \ldots, 2 n \\ \mathbb{Z} & \text { in dimension } 2 n+1 \\ 0 & \text { otherwise }\end{cases}
$$

Exercise 18.7. Prove that the Lens space $4(n, q)$ is an orientable manifold.

Exercise 18.8. Let $q$ be a positive integer greater than one.
(a) Show that the integer cohomology of $K\left(\mathbb{Z}_{q}, 1\right)$ is

$$
H^{*}\left(K\left(\mathbb{Z}_{q}, 1\right) ; \mathbb{Z}\right)= \begin{cases}\mathbb{Z} & \text { in dinension } 0 \\ \mathbb{Z}_{\mathbf{q}} & \text { in every positive even dimension } \\ 0 & \text { otherwise. }\end{cases}
$$

(b) Using the fibering $S^{1} \rightarrow K\left(\mathbb{Z}_{q}, 1\right) \rightarrow \mathbb{C} P^{\infty}$, compute $H^{*}\left(K\left(\mathbb{Z}_{q}, 1\right) ; \mathbb{Z}_{p}\right)$ where $p$ is a prime:

Exercise 18.9. Let $n$ and $q$ be positive integers. Show that

$$
H^{*}\left(K\left(\mathbb{Z}_{q}, n\right) ; \mathbb{Q}\right)= \begin{cases}\mathbb{Q} & \text { in dimension } \mathbf{0} \\ 0 & \text { otherwise },\end{cases}
$$

Therefore, by the structure theorem for finitely generated Abelian groups, the rational cohomology of $K(A, n)$ is trivial for a finitely generated torsion Abelian group.
Exercise 18.10. Determine the product structures of $H^{*}(L(n, q))_{i} H^{*}\left(K\left(\mathbb{Z}_{i}^{*}\right.\right.$, $1)$, and $H^{*}\left(K\left(\mathbb{Z}_{q}, 1\right) ; \mathbb{Z}_{p}\right)$. In particular, show that

$$
H^{*}\left(R P^{\infty}\right)=\mathbb{Z}[a] /\left(2 a, 2 a^{2}, 2 a^{3}, \ldots\right) ; \operatorname{dim} a:=2
$$

and

$$
H^{*}\left(\mathbb{R} P^{\infty} ; \mathbb{Z}_{2}\right)=\mathbb{Z}_{2}[x], \quad \operatorname{dim} x=1
$$

## The Cohomology of $K(\mathbb{Z}, 3)$

Since $\pi_{q}\left(S^{3}\right)=0$ for $q<3$ and $\pi_{3}\left(S^{3}\right)=Z$, one may wonder if the sphere $S^{3}$ is á $K(Z, 3)$. One way of deciding this is to compute the cohomology of $K(\mathbb{Z}, 3)$. We first observe that

$$
\Omega K(\mathbb{Z}, 3)=K(\mathbb{Z}, 2)=\mathbf{C} \boldsymbol{P}^{\infty} ; \quad \therefore \quad \therefore \quad \therefore,
$$

whose cohomology we know to be $\mathbb{Z}[x]$ from Exercise 18.4. Since by Remark 17.13, every CW complex has a gaod, cover, we can apply the spectral sequence of the path fibration

$$
\begin{aligned}
K(\mathbb{Z}, \mathbf{2}) \rightarrow & P K(\mathbb{Z}, \mathbf{3}) \\
& \downarrow \\
& \ddots
\end{aligned} \quad \cdots \quad \cdots,
$$

to compute the cohomology of $K(\mathbf{Z}, 3)$.
By Leray's theorem with integer coefficients (15.11), the $E_{2}$ term of the spectral sequence is

$$
E E^{p . q}=H^{p}(K(\mathbb{Z}, 3)) \otimes H^{q}\left(C P^{\infty}\right)
$$

and its product structure is that of the tensor product of $\boldsymbol{H}^{*}(K(Z, 3))$ and $H^{*}\left(\right.$ CP $\left.^{\infty}\right)$.

Since the total space $P K(Z, 3)$ is contractible, the $E_{\infty}$ term is 0 except for $E_{\infty}^{0.0}$. The plan now is to "create" elements in the bottom row of the $E_{2}$ picture which would sooner or later "kill off" all the nonzero elements of the spectral sequence. There can be no nonzero elements in the bottom row of columns 1 and 2, for any such element would survive to $E_{\infty}$. However there must be an element $s$ in column 3 to kill off $a$. Thus

$$
d_{3} a=s
$$

and

$$
d_{3}\left(a^{2}\right)=2 a d_{3} a=2 a s
$$

There must be an element $y$ in column 6 to kill off as for otherwise as would survive to $E_{\infty}$. Therefore $H^{6}(K(Z, 3)) \neq 0$. This proves that $S^{3}$ is not a $K(Z, 3)$. Equivalently, it shows the existence of nontrivial higher homotopy groups for $S^{3}$. Later in this section we will compute $\pi_{4}$ and $\pi_{5}$ of $S^{3}$.

As for the cohomology ring of $K(Z, 3)$, we can be more precise. First, note that $y=d(a s)=(d a) \cdot s=s^{2}$. From the picture of $E_{2}$, it is clear that $H^{6}(K(Z, 3))=\mathbf{Z}_{2}$. Therefore, $2 s^{2}=0$. Now a nonzero element in $E_{2}^{7.0}=$ $H^{7}(K(Z, 3))$ can be killed only by $a^{3}$ under $d_{7}$. Since $d_{3}\left(a^{3}\right)=3 a^{2} \neq 0, a^{3}$ does not even live to $E_{4}$. So $H^{7}(K(Z, 3))=0$. Since $d_{3}\left(a^{2} s\right)=2 a s^{2}=0, a^{2} s$ would live to $E_{\infty}$ uniess $d_{s}\left(a^{2} s\right)=t \neq 0$. In $E_{4}=E_{5}, a^{2} s$ generates the cyclic group $\mathbf{Z}_{3}$. Since $t$ is the element that kills $a^{2} s$ in $E_{5}, t$ is of order 3. In summary the first few cohomology groups of $K(Z, 3)$ are

| $q$ | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $H^{4}$ | $Z$ | 0 | 0 | $Z$ | 0 | 0 | $Z_{2}$ | 0 | $Z_{3}$ |
| generators | 1 |  |  | $s$ |  |  | $s^{2}$ |  | $t$ |

Exisaciss 18.12. Show that $H^{*}(K(Z, n) ; Q)$ is an exterior algobra on one generator of dimension $n$ if $n$ is odd and a polynomial algebra on one generator of dimension $n$ if $n$ is even. In either case we say that the cohomology of $K(Z, n)$ is free on one generator (eee Section 19 for the definition of a free algebra).

## The Transgression

Let $\pi: E \rightarrow X$ be a fibration with connected fiber $F$ over a space with a good cover 4 . In computing the differentials of the spectral sequence of $E$ using what we have developed $s 0$ far, one often encounters ambiguities which cannot be resolved without further clues. One such clue is knowlodge of the transgressive elements. An element $\omega$ in

$$
H^{4}(F) \subset E_{2}^{0,4}=H^{0}\left(\mu, X^{2}(F)\right)
$$

is called transgressive if it lives to $E_{8+1}$; that is,

$$
d_{2} \omega=d_{3} \omega=\cdots=d_{8} \omega=0
$$

An alternative characterization of a transgressive element is given in the following proposition, which we phrase in the language of differential forms. Of course by replacing forms with singular cochains, the proposition is equally true in the singular setting with arbitrary coefficients.

Propocition 18.13. Let $\pi: E \rightarrow M$ be a fibration with fiber $F$ in the differentiable category. An element $\omega$ in $H^{( }\left(F^{7}\right)$ is transgressive if it is the restriction of a global form $\psi$ on $E$ such that $d \psi=\boldsymbol{\pi}^{*} \tau$ for some form $\tau$ on the base $M$.

Remark 18.13.1. Because $\pi^{*}$ is injective and

$$
\pi^{*} d \tau=d d \psi=0,
$$

we actually have

$$
d \tau=0,
$$

so the form $\tau$ defines a cohomology class on $M$.
Proof of proposition 18.13. Let $\mathfrak{u}$ be a good cover of $M$. If $\omega$ is transgressive, then by (14.12) it can be extended to a cochain $\alpha=\alpha_{0}+\cdots+\alpha_{8}$ in the double complex $C^{*}\left(\pi^{-1} \mathbb{U}, \Omega^{*}\right)$ such that $D \alpha=\pi^{*} \beta$ for some Coch cocycle $\beta$ on $M$.

$$
\begin{array}{|l|l|l|l|l|}
\alpha_{0} & & & & \\
& \alpha_{1} & & & \\
& & & & \\
& & & \alpha_{4} & x^{*} \beta \\
\hline
\end{array}
$$

By the collating formula (9.5),
(*)

$$
\psi=\sum_{i=0}^{q}(-1)^{i}\left(D^{\prime \prime} K\right)^{i} \alpha_{i}+(-1)^{q+1} K\left(D^{\prime \prime} K\right)^{q} \pi^{*} \beta
$$

is a global form on $E$ corresponding to $\alpha$. From ( ${ }^{*}$ ) we see that

$$
d \psi=(-1)^{q+1}\left(D^{\prime \prime} K\right)^{q+1} \pi^{*} \beta=\pi^{*} \tau
$$

where $\tau=\left(-D^{\prime \prime} K\right)^{a+1} \beta$ is by (9.8) a closed global form on $M . \therefore$
Conversely suppose $\psi$ is a global form on $E$ with $d \psi=\pi^{*} \tau$. Then by restriction $\psi$ defines a cochain in $C^{0}\left(\pi^{-1} \mathfrak{U}, \Omega^{*}\right)$ such that $D \psi=\pi^{*} \tau$.

It is a simple exercise (analogous to Prop. 8.8) to show that $\psi$ is $D$ cohomologous to a cochain $\alpha$ in $\mathcal{C}^{*}\left(\pi^{-1} \mathfrak{U}, \Omega^{*}\right)$ such that $D \alpha=\pi^{*} \beta$ for some Cech cocycle $\beta$ in $C^{*}\left(\mathcal{U}, \Omega^{*}\right)$.

Exercise 18.13.2. Prove this assertion.
Let $\bar{\psi}$ be the global form corresponding to $\alpha$ given by the collating formula (*). Then $\left.\bar{\psi}\right|_{F}=\left.\psi\right|_{F} \in H^{q}(F)$ is transgressive.

We will now apply the singular analogue of Proposition 18.13 to obtain one of the most useful vanishing criteria for the differentials of a spectral sequence.

Proposition 18.14. In mod 2 cohomology, if $\alpha$ is a transgressive, so is $\alpha^{2}$.
Proof. Let $\psi$ be the singuiar cochain on $E$ given by Prop. 18.13. Since $\psi$ restricts to $\alpha$ on a fiber, $\psi^{2}$ restricts to $\alpha^{2}$. With $\mathbb{Z}_{2}$ coefficients,

$$
d\left(\psi^{2}\right)=2 \psi d \psi=0
$$

Therefore, by Prop. 18.13 again, $\alpha^{2}$ is transgressive.
Exercise 18.15. Compute $H^{*}\left(K\left(\mathbb{Z}_{2}, 2\right) ; \mathbb{Z}_{2}\right)$ and $H^{*}\left(K\left(\mathbb{Z}_{2}, 2\right) ; \mathbb{Z}\right)$ up to dimension 6.

Exercise 18.16. Compute $H^{*}\left(K\left(\mathbb{Z}_{2}, 3\right) ; \mathbb{Z}_{2}\right)$ and $H^{*}\left(K\left(\mathbb{Z}_{2}, 3\right) ; \mathbb{Z}\right)$ up to dimension 6.

Exercise 18.16.1. Compute the homology $H_{\#}\left(K\left(\mathbb{Z}_{2}, 4\right) ; \mathbb{Z}\right)$ up to dimension 6.

Basic Tricks of the Trade
In homotopy theory every map $f: A \rightarrow B$ from a space $A$ to a pathconnected space $B$ may be viewed as either an inclusion or a fibering. We can see this as follows.
(18.17) Inclusion

Applying the telescoping idea just once, we construct the mapping cylinder of $f$ (see Figure 18.4):

$$
M_{f}=(A \times I) \cup B /(a, 1) \sim f(a) .
$$

Figure 18.4
It is clear that the mapping cylinder $M_{f}$ has the same bomotopy type as $B$ and that $A$ is included in $M_{f}$. Indeed the following diagram is commutative:

(18.18) Fibering

Let $f: A \rightarrow B$ be any map, with $B$ path connected. By (18.7) we may assume that $f$ is an inclusion, i.e., $A$ is a subspace of $B$ (Figure 18.5). Define $L$ to be the space of all paths in $B$ with initial point in $A$. By shrinking every

Figure 18.5
path to its initial point, we get a homotopy equivalence

$$
L \simeq A
$$

On the other hand by projecting every path to its eadpoint, we get a fibering

whose fiber is $\Omega_{\#}$, the space of all paths from a point in $B$ to $A$. So up to homotopy equivalence, $f: A \rightarrow B$ is a fibering.

## Postnikov Approximation

Let $X$ be a $C W$ complex with homotopy groups $\pi_{d}(X)=\pi_{f}$. Although $X$ has the same homotopy groups as the product space $\Pi K\left(\pi_{q}, q\right)$, in general . it will not have the same homotopy type as $\Pi K\left(x_{q} ; q\right)$. However, up to homotopy every CW complex can be thought of as a "twisted product" of Eilenberg-MacLane spaces in the following sense.

Proponition 18.19 (Postnikov Approximation). Every connected CW complex can be approximated by a twisted product of Eilenberg-MacLane spaces; more precisely, for each $n$, there is a sequence of fibrations $Y_{4} \rightarrow Y_{q-1}$ with the $K\left(\boldsymbol{\pi}_{\mathrm{f}}, q\right)$ 's as fibers and commuting maps $X \rightarrow \mathbf{Y}_{q}$

such that the map $X \rightarrow Y_{q}$ induces an isomorphism of homotopy groups in dimensions $\leq q-1$.

Such a sequence of fibrations is called a Postnikov tower of $X$. In view of (18.18) that every map in homotopy theory is a fibration, this proposition is perhaps not so surprising.

We first explain a procedure for killing the homotdpy groups of $X$ above a given dimension. For example, to construct $K\left(\pi_{1}, 1\right)$ we kill off the homotopy groups of $X$ in dimensions $\geq 2$ as follows. If $\alpha: S^{2} \rightarrow X$ represents a
nontrivial element in $\pi_{2}(X)$, we attach a 3 -cell to $X$ via a:

$$
x \cup e^{3}=x \amalg e^{3} / x \sim e(x), \quad x \in e_{3} .
$$

This procedure does not change the fundamental group of the speco-by Proposition 17.11 attaching an $n$-cell to $X$ could kill an element of $x_{n-1}(X)$ but does not affect the homotopy of $X$ in dimensions $\leq n-2$. For each generator of $\pi_{2}(X)$ we attach a 3 -cell to $X$ as above. In this way we create a new space $X_{1}$ with the same fundamental group as $X$ but with no $\pi_{2}$. Iterating this procedure we can kill all higher homotopy groups. This gives $\mathbf{Y}_{1}$.

Proor of propostrion 18.19. To construct $Y_{n}$ we kill off all homotopy of $X$ in dimensions $\geq n+1$ by attaching cells of dimensions $\geq n+2$. Then

$$
x_{k}\left(Y_{n}\right)= \begin{cases}0, & k \geq n+1 \\ x_{k}, & k=1,2, \ldots, n .\end{cases}
$$

Having constructed $Y_{n}$, the space $Y_{a-1}$ is obtained from $Y_{n}$ by killing the homotopy of $Y_{n}$ in dimension $n$ and above. By (18.18), the inclusions

$$
X \subset Y_{n} \subset Y_{n-1} \subset \cdots \subset Y_{1}
$$

may be converted to fiberings. From the exact homotopy sequence of a fibering we see that the fiber of $Y_{\mathbf{q}} \rightarrow Y_{\mathbf{q}-\mathrm{i}}$ is the Eilenberg-Mackane spece $K\left(\pi_{4}, q\right)$.

## Computation of $\pi_{4}\left(S^{3}\right)$

This computation of $\pi_{4}=\pi_{4}\left(S^{3}\right)$ is based on the fact that the homotopy group $\pi_{4}$ appears as the first nontrivial homology group of the EilenbergMacLane space $K\left(x_{4}, 4\right)$. If this Eilenberg-MacLane space can be fitted into some fibering, its homology may be found from the spectral sequence. Such a fibering is provided by the Postnikov approximation.

Let $Y_{4}$ be a space whose homotopy agrees with $\boldsymbol{S}^{3}$ up to and including dimenision 4 and vanishes in higher dimensions. To get such a space we kill off all homotopy groups of $\boldsymbol{S}^{3}$ in dimensions $\geq 5$ by attaching cells of dimensions $\mathbf{2 6}$. So

$$
\mathbf{Y}_{4}=S^{3} \cup e^{6} \cup \ldots
$$

By Proposition 17.12, $H_{4}\left(Y_{4}\right)=H_{s}\left(Y_{4}\right)=0$. The Postnikov approximation theorem gives us a fibering

$$
K\left(\pi_{4}, 4\right) \rightarrow Y_{4}
$$

The $E^{2}$ term of the homology spectral sequence of this fibering is

$K(\mathbb{Z}, 3)$
where the homology of $K(\mathbb{Z}, 3)$ is obtained from (18.11) and the universal coefficient theorem (15.14). Since $H_{4}\left(Y_{4}\right)=H_{5}\left(Y_{4}\right)=0$, the arrow shown must be an isomorphism. Hence $\pi_{4}\left(S^{3}\right)=\mathbb{Z}_{2}$.

More generally since $Y_{q}=S^{3} \cup e^{q+2} \cup \ldots$, by (17.12),

$$
H_{q}\left(Y_{q}\right)=H_{q+1}\left(Y_{q}\right)=0 .
$$

Hence from the homology $E^{2}$ term of the fibration

we get

$$
\begin{equation*}
\pi_{q}\left(S^{3}\right)=H_{4+1}\left(Y_{4-1}\right) . \tag{18.20}
\end{equation*}
$$

## The Whitehead Tower

The Whitehead tower is a sequence of fibrations, dual to the Postnikov approximation in a certain sense, which generalizes the universal covering of a space. Unlike the Postnikov construction, where we kill successively the homotopy groups above a given dimension, here the idea is to kill at each stage all the homotopy groups below a given dimension.

Up to homotopy the universal covering of a space $X$ may be constructed as follows. Write $\pi_{q}=\pi_{d}(X)$. By attaching cells to $X$ we can kill all $\pi_{g}$ for $q \geq 2$ as in (18.19). Let $Y=X \cup e^{3} \cup \cdots$ be the space so obtained; $Y$ is a $K\left(\pi_{1}, 1\right)$ containing $X$ as a subspace. Consider the space $\Omega_{*}^{X}$ of all paths in $\boldsymbol{Y}$ from a base point * to $X$ (Figure 18.6). The endpoint map: $\Omega_{*}^{\boldsymbol{X}} \rightarrow X$ is a

Figure 18.6
fibration with fiber $\Omega Y=\Omega K\left(\pi_{1}, 1\right)=K\left(\pi_{1}, 0\right)$. From the homotopy exact sequence of the fibering

$$
\begin{array}{r}
K\left(\pi_{1}, 0\right) \rightarrow \Omega_{*}^{X} \\
\\
\downarrow \\
X
\end{array}
$$

we see that $\pi_{1}\left(\Omega_{*}^{X}\right)=0$. Hence $X_{1}=\Omega_{*}^{X}$ is the universal covering of $X$ up to homotopy.

We will now generalize this procedure to obtain a sequence of fibrations

such that
(a) $X_{n}$ is $n$-connected, i.c., $\pi\left(X_{n}\right)=0$ for all $q \leq n$;
(b) above dimension $n$ the homotopy groups of $X_{n}$ and $X$ agree;
(c) the fiber of $X_{n} \rightarrow X_{n-1}$ is $K\left(\pi_{n}, n-1\right)$.

This is the Whitehead tower of $X$. To construct $X_{n}$ from $X_{n-1}$, we first kill all $\pi_{d}\left(X_{n-1}\right), q \geq n+1$, by attaching cells to $X_{n-1}$. This gives a

$$
K\left(\pi_{n}, n\right)=X_{n-1} \cup e^{n+2} \cup \ldots
$$

Next let $X_{n}=\Omega_{x_{n}-1}^{X_{n}}$ be the space of all paths in $K\left(\pi_{n}, n\right)$ from a base point * to $X_{n-1}$. The endpoint map: $X_{n} \rightarrow X_{n-1}$ has fiber $\Omega K\left(\pi_{n}, n\right)=K\left(\pi_{n}, n-1\right)$. From the homotopy exact sequence of the fibering

$$
\begin{aligned}
K\left(\pi_{n}, n-1\right) \rightarrow & X_{n} \\
& \downarrow \\
& X_{n-1}
\end{aligned}
$$

it is readily checked that $\pi_{q}\left(X_{n}\right)=\pi_{q}\left(X_{n-1}\right)$ for $q \geq n+1$; and $\pi_{q}\left(X_{n}\right)=0$ for $q \leq n-2$; furthermore,

$$
\begin{equation*}
0 \rightarrow \pi_{n}\left(X_{n}\right) \rightarrow \pi_{n}\left(X_{n-1}\right) \xrightarrow{0} \pi_{n-1}\left(\Omega K\left(\pi_{n}, n\right)\right) \rightarrow \pi_{n-1}\left(X_{n}\right) \rightarrow 0 \tag{18.21}
\end{equation*}
$$

is exact. Here $\pi_{n}\left(X_{n-1}\right)=\pi_{n}$ by the induction hypothesis, and the problem is to show that $\partial: \pi_{n}\left(X_{n-1}\right) \rightarrow \pi_{n-1}\left(\Omega K\left(\pi_{n}, n\right)\right)$ is an isomorphism. Now the inclusion $X_{n-1} \subset K\left(\pi_{n}, n\right)=X_{n-1} \cup e^{n+2} \cup \cdots$ induces by (17.11) an isomorphism

$$
\pi_{n}\left(X_{n-1}\right) \simeq \pi_{n}\left(K\left(\pi_{n}, n\right)\right) .
$$

Moreaver, the definition of the boundary map

$$
\partial: \pi_{n}\left(X_{n-1}\right) \rightarrow \pi_{n-1}\left(\Omega K\left(\pi_{n}, \underline{n}\right)\right)
$$

(see (17.4)) is precisely how $\pi_{n}\left(K\left(\pi_{n}, n\right)\right)$ was identified with $\pi_{n-1}\left(\Omega K\left(\pi_{n}, n\right)\right)$ in Proposition 17.2. Therefore $\partial$ is an isomorphism and $\pi_{n}\left(X_{n}\right)=\pi_{n-1}\left(X_{n}\right)=$ 0 in (18.21). This completes the construction of the Whitehead tower.

As a first application of the Whitehead tower we will prove Serre's theorem on the homotopy groups of the spheres. We call a sphere $S^{n}$ odd or even according to whether $n$ is ocid or even.

Theorem 18.22 (Serre). The homotopy groups of an odd sphere $S^{n}$ are torsion except in dimension $n$; those of an even sphere $S^{n}$ are torsion except in dimensions $n$ and $2 n-1$.

Proof. The essential facts to be used in this proof are the following:
(a) in the Whitehead tower of any space $X, \pi_{4+1}(X)=H_{4+1}\left(X_{4}\right)$; hence,

$$
\pi_{4+1}(X) \otimes \mathbb{Q}=H_{\mathbf{q}+1}\left(X_{\mathbf{q}} ; \mathbb{Q}\right) ;
$$

(b) the rational cohomology ring of $K(\pi, n)$ is trivial for a torsion finitely generated Abelian group $\pi$ and is free on one generator of dimension $n$ for $\pi=\mathbf{Z}$ (Exercises 18.9 and 18.12).

Since $S^{n}$ is $(n-1)$-connected and $\pi_{n}\left(S^{n}\right)=Z$, the Whitehead tower begins with

$$
\begin{equation*}
K(\mathbf{Z}, n-1) \rightarrow X_{n} \tag{18.22.1}
\end{equation*}
$$

For the rest of this proof we write $\pi_{q}$ for $\pi_{d}\left(S^{n}\right)$. First consider the case where $n$ is odd. We will assume $n \geq 3$. Then the rational cohomology of $K(\mathbb{Z}, n-1)$ is a polynomial algebra on one generator of dimension $n-1$ and the cohomology spectral sequence of the fibration (18.22.1) has $E_{2}$ term

(Here we are using the cohomology spectral sequence to take advantage of the product structure.) The bottom arrow is an isomorphism because $H_{n-1}\left(X_{n} ; \mathbb{Q}\right)=0$; the other arrows are isomorphisms by the product structure. From the spectral sequence we see that $X_{n}$ has trivial rational cohomology, hence trivial rational homology. By Remark (a) above, $\pi_{n+1}$ is torsion. Now consider the next step of the Whitehead tower:

$$
\begin{aligned}
K\left(\pi_{n+1}, n\right) \rightarrow & X_{n+1} \\
& \downarrow \\
& X_{n}
\end{aligned}
$$

Since both $X_{n}$ and $K\left(\pi_{n+1}, n\right)$ have trivial rational homology, so does $X_{n+1}$. By Remark (a) acain, $\pi_{n+2}=H_{n+2}\left(X_{n+1}\right)$ is torsion. By induction for all $q \geq n+1, X_{q}$ has trivial rational homology and $\pi_{q}$ is torsion.

Now suppose $n$ is even. Then the rational cohomology of $K(Z, n-1)$ is an exterior algebra and the $E_{2}$ term of the rational homology sequence of the fibration (18.22.1) has only four nonzero boxes:

The arrow shown is an isomorphism. because $X_{n}$ is $n$-connected. So

$$
H_{*}\left(X_{n} ; Q\right)= \begin{cases}Q & \text { in dimensions } 0,2 n-1 \\ 0 & \text { otherwise. }\end{cases}
$$

Suppose $n>2$. Then $n+1<2 n-1$. By Remark (a), $\boldsymbol{\pi}_{n+1}=H_{n+1}\left(\dot{X}_{n}\right)$ is
torsion. Since $H_{s}\left(K\left(\pi_{m+1}, n\right) ; \mathbf{Q}\right)$ is trivial, from the fibration

$$
\begin{aligned}
K\left(x_{n+1}, n\right) \rightarrow & X_{n+1} \\
& \downarrow \\
& X_{n}
\end{aligned}
$$

we conclude that $X_{n+1}$ has the same rational homology as $X_{n}$. This sets the induction going again, showing that $\pi_{9}$ is torsion, until we hit $\pi_{2 n-1}=$ $H_{2 n-1}\left(X_{2 n-2}\right)$, which is not torsion. In fact, $\pi_{2 n-1}$ has one infinite cyclic generator and possibly some torsion generators. At this point we may assume $n \geq 2$. By Remark (b), the rational cohomology ring .

$$
H^{*}\left(K\left(\pi_{2 n-1}, 2 n-2\right) ; \mathbf{Q}\right)
$$

is a polynomial algebra on one generator, so the cohomology $E_{2}$ term of the fibration

$$
\begin{aligned}
K\left(\pi_{2 m-1}, 2 n-2\right) \rightarrow & X_{2 n-1} \\
& \downarrow \\
& X_{2 m-2}
\end{aligned}
$$

is

Since $H_{2 n-1}\left(X_{2 n-1}\right)=0$, the arrows shown must all be isomorphisms. It follows that the rational cohomology groups of $X_{4}$ are trivial for all $q>2 n-1$ and the homotopy groupe $\pi\left(S^{(N)}\right.$ are torsion for all $q>2 n-1$.

Exercise 18.23. Give a proof of Theorem 18.22 based on the Postnikov approximation.

Computation of $\pi_{5}\left(S^{3}\right)$
If we try to compute $\pi_{5}\left(S^{3}\right)$ using the Postnikov approximation, we very quickly run up against an ambiguity in the spectral sequence. For by $(18.20), \pi_{5}\left(S^{3}\right)=H_{6}\left(Y_{4}\right)$, but to compute $H_{6}\left(Y_{4}\right)$ from the homology spectral
sequence of the fibering

we will have to decide whether the arrow shown is the zero map or an isomorphism. With the tools at our disposal, this cannot be done. (For the homology of $K\left(\mathbb{Z}_{2}, 4\right)$ and $K(Z, 3)$ see (18.16.1) and (18.11).).

In this case the Whitehead tower is more useful. Since $S^{3}$ is 2 -connected, the Whitehead tower up to $X_{4}$ is

$$
\begin{aligned}
K\left(\pi_{4}, 3\right) \rightarrow & X_{4} \\
& \downarrow \\
K(Z, 2) \rightarrow & X_{3} \\
& \downarrow \\
& S^{3} .
\end{aligned}
$$

From the construction of the Whitehead tower and the Hurewicz isomorphism, $\pi_{5}\left(S^{3}\right)=\pi_{5}\left(X_{4}\right)=H_{5}\left(X_{4}\right)$. So we can get $\pi_{5}$ by computing the homology of $X_{4}$. This method also gives $\pi_{4}\left(S^{3}\right)$, which is $H_{4}\left(X_{3}\right)$.

The cohomology of $X_{3}$ may be computed from the spectral sequence of the fibration $K(Z, 2) \rightarrow X_{3} \rightarrow S^{3}$, whose $E_{2}$ term is

Since $d_{2}$ is clearly zero, $E_{2}=E_{3}$. Next $d_{3}: E_{3}^{0.2} \rightarrow E_{3}^{3.0}$ is an isomorphism because $X_{3}$ is 3 -connected. By the antiderivation property of the differential $d_{3}$, which we will write as $d$ here,

$$
d\left(x^{n}\right)=n x^{-1} d x=n x^{-1} u
$$

Hence the integral cohomology and homology of $X_{3}$ are

| $q$ | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $H^{q}\left(X_{3}\right)$ | $Z$ | 0 | 0 | 0 | 0 | $Z_{2}$ | 0 | $Z_{3}$ | 0 | $Z_{4}$ | 0 | $Z_{5}$ |
| $H_{4}\left(X_{3}\right)$ | $Z$ | 0 | 0 | 0 | $Z_{2}$ | 0 | $Z_{3}$ | 0 | $Z_{4}$ | 0 | $Z_{5}$ | 0 |,

where the homology is obtained from the cohomology by the universal coefficient theorem (15.14.1).

The homology spectral sequence of the fibration $K\left(\pi_{4}, 3\right) \rightarrow X_{4} \rightarrow X_{3}$ has $E_{2}$ term

which shows that $\pi_{4}=\mathbf{Z}_{2}$, since $X_{4}$ is 4 connected.
By Exercise 18.16, $H_{4}\left(K\left(Z_{2}, 3\right)\right)=0$ and $H_{5}\left(K\left(Z_{2}, 3\right)\right)=Z_{2}$. Since the only homomorphism from $Z_{3}$ to $Z_{2}$ is the zero map, $d_{6}$ in the diagram above is zero. Hence $H_{5}\left(X_{4}\right)=Z_{2}$ and $\boldsymbol{\pi}_{5}\left(S^{3}\right)=\pi_{5}\left(X_{4}\right)=H_{5}\left(X_{4}\right)=Z_{2}$.

Exercise 18.24. Given a prime $p$, find the least $q$ such that the homotopy group $x_{d}\left(S^{3}\right)$ has $p$-torsion.

## §19 Rational Homotopy Theory

By some divine justice the homotopy groups of a finite polyhedron or a manifold seem as difficult to compute as they are easy to define. For a simpte space like $S^{3}$, already, the homotopy groups appear to be completely irregular. The computation of $\pi_{4}\left(S^{3}\right)$ and $n_{s}\left(S^{3}\right)$ in the preceding section should have given the reader some idea of the complexity that is involved.

However, if one is willing to forego the torsion information, by considering, for instance, the rational homotopy groups $\pi_{d}(X) \otimes Q$, then some general theorems are possible. One such result is Serre's theorem on the homotopy groups of the spheres (Th. 18.22). In the late sixties Dennis Sullivan shed new light on the computation of rational homotopy by the upe of difierential forms. This section is a brief introduction to Sullivan's worle At though Sullivan's theory, with an appropriate definition of the rational differential forms, is applicable to CW complexes, we will consider only differentiable manifolds. As applications we derive again Serre's theorem and also compute some low-dimensional homotopy groups of the wedge $S^{2} \vee S^{2}$.

## Minimal Models

Let $A=\bigoplus_{i \geqslant 0} A^{i}$ be a differential graded commutative algebra over $\mathbf{R}$; here the differential is an antiderivation of degree 1:

$$
d(a \cdot b)=(d a) \cdot b+(-1)^{d m a} a \cdot d b ;
$$

and the commutativity is in the graded sense:

$$
a \cdot b=(-1)^{\operatorname{dma}+\operatorname{dm}} b \cdot a
$$

In this section we will consider only finitely generated differential graded commutative algebras. Such an algebra is free if it satisfies no relations other than those of associativity and graded commutativity. We write $\mathbf{N}\left(x_{1}\right.$, $\ldots, x_{k}$ ) for the free algebra generated by $x_{1}, \ldots, x_{k}$; this algebra is the tensor product of the polynomial algebra on its even-dimensional penerators and the exterior algebra on its odd-dimensional genernoth. An clement in $A$ is said to be decomposable if it is a sum of products of poxitive elements in $A$, i.e, $a \in A^{+} \cdot A^{+}$, where $A^{+}=\bigoplus_{i>0} A^{i}$. A differential graded algebra $N$ is called a minimal model for $A$ if:
(a) $\mathcal{M}$ is free;
(b) there is a chain map $f: \mathscr{H} \rightarrow A$ which induces an isomorphien in - cohomology;
(c) the differential of a generator is either zero or decomposable (a differential graded algebra satisfying this condition is said to be minimal)

A minimal model of a manifold $M$ is by definition a minimal model of its algebra of forms $\mathbf{\Omega}^{\boldsymbol{*}}(\boldsymbol{M})$.

## Examples of Minimal Models

Exanple 19.1. The de Rham cohomology of the odd sphere $S^{2 n-1}$ is an exterior algobra on one generator. Hence a minimal model for $S^{2 e-2}$ is $\Lambda(x)$,
$\operatorname{dim} x=2 n-1$, with

$$
f: x \mapsto \text { volume form on } S^{2 n-1}
$$

Example 19.2. The de Rham cohomology of the even sphere $S^{2 n}$ is $\mathbf{R}[a] /\left(a^{2}\right), \operatorname{dim} a=2 n$. To construct a minimal model, we need a generator $x$ in dimension $2 n$ to map onto $a$ and a generator $y$ in dimension $4 n-1$ to kill off $x^{2}$. Since $\operatorname{dim} y$ is odd, $y^{2}=0$. So the complex $\Lambda(x, y), d x=0$, $d y=x^{2}$ can be visualized as the array

which shows that the cohomology of $\Lambda(x, y)$ is $R[x] /\left(x^{2}\right)$. The minimal model of $S^{2 n}$ is $\Lambda(x, y)$, and the map $f: \Lambda(x, y) \rightarrow \Omega^{*}\left(S^{2 n}\right)$ is given by

$$
\begin{aligned}
f & : x \mapsto \text { volume form } \omega \text { on } S^{2 n} \\
& y \mapsto 0 .
\end{aligned}
$$

Example 19.3. Since the de Rham cohomology of the complex projective space $C P^{n}$ is $\mathbf{R}[x] /\left(x^{n+1}\right)$, $\operatorname{dim} x=2$, by reasoning similar to the preceding example, a minimal model is $\Lambda(x, y), \operatorname{dim} y=2 n+1, d x=0, d y=x^{n+1}$.

A differential graded algebra $A$ is said to be 1-connected if $H^{0}(A)=\mathbf{R}$ and $H^{1}(A)=0$.

Proposition 19.4. If the differential graded algebra A is 1-connected and has finite-dimensional cohomology, then it has a minimal model.

Proof. Let $a_{1}, \ldots, a_{k}$ be the 2 -dimensional cycles in $A$ which represent a basis of the second cohomology $H^{2}(A)$. Define $\boldsymbol{N}_{2}=\boldsymbol{M}\left(a_{1}, \ldots, a_{k}\right)$ where $\operatorname{dim} a_{1}=2$ and $d a_{1}=0$, and set

$$
\begin{gathered}
f: \boldsymbol{N}_{2} \rightarrow A \\
a_{i} \mapsto a_{i} .
\end{gathered}
$$

At this stage $f$ induces an isomorphism in cohomblogy in dimensions less than 3 and an injection in dimension 3, because $\Lambda\left(a_{1}, \ldots, a_{k}\right)$ has nothing in dimension 3. We will prove inductively that for any $n$ there is a minimal free algebra $\boldsymbol{N}_{n}$ together with a chain map $f: \boldsymbol{M}_{n} \rightarrow A$ such that
(a) the algebra $\mathscr{K}_{n}$ has no elements in dimension 1 and no generators in dimensions greater than $n$;
(b) the map $f$ induces an isomorphism in cohomology in dimensions leas thap $n, 1$ and an injection in dimension $n+1$.

So suppose this is true for $n=q-1$. By hypothesis there are exact sequences

$$
0 \rightarrow H^{q}\left(\mathcal{N}_{4}-1\right) \rightarrow H^{q}(A) \rightarrow \text { coker } H^{q}(f) \rightarrow 0
$$

and

$$
0 \rightarrow \operatorname{ker} H^{\varrho^{+1}}(f) \rightarrow H^{++1}\left(\mathcal{M}_{\&-1}\right) \rightarrow H^{+1}(A)
$$

Let $\left\{\left[b_{i}\right]\right\}_{i_{G} I}$ be a basis of coker $H^{4}(f)$ and $\left\{\left[x_{j}\right]\right\}$ a basis of ker $H^{+1}(f)$, with $b_{i}$ in $A^{4}$ and $x_{j}$ in $\mathscr{M}_{q-1}^{q+1}$, where $\mathscr{M}_{-1}^{q+1}$ denotes the elements of degree $q+1$ in $\boldsymbol{M}_{q-1}$. The $x_{j}$ 's are decomposable because the generators of $\mathcal{N}_{q-1}$ are all of dimension $\leq q-1$. The idea is to introduce new elements in $\mathscr{M}_{q-1}$ to kill both coker $H^{4}(f)$ and ker $H^{++1}(f)$. Define

$$
\mathscr{M}_{i}=\mathscr{M}_{i-1} \otimes \Lambda\left(b_{i}, \xi_{j}\right), \quad \operatorname{dim} b_{i}=\operatorname{dim} \xi_{j}=q
$$

$\boldsymbol{N}_{4}$ is again a free minimal algebra, with differential

$$
\begin{aligned}
& d(m \otimes 1)=(d m) \otimes 1 \\
& d\left(1 \otimes b_{i}\right)=0 \\
& d\left(1 \otimes \xi_{j}\right)=x_{j} \otimes 1 .
\end{aligned}
$$

We extend $f: \mathscr{M}_{q-1} \rightarrow A$ to $f: \mathcal{M}_{q} \rightarrow A$ by

$$
\begin{aligned}
& f(m \otimes 1)=f(m), \\
& f\left(1 \otimes b_{i}\right)=b_{i}, \\
& f\left(1 \otimes \xi_{j}\right)=\alpha_{j},
\end{aligned}
$$

where $\alpha_{j}$ is an element of $A$ such that $f\left(x_{j}\right)=d \alpha_{j}$. It is easy to check that this new $f$ is again a chain map.

We now show that $H^{4}(f): H^{4}\left(\mathbb{N}_{\uparrow}\right) \rightarrow H^{4}(A)$ is an isomorphism. Suppose

$$
z=\sum v_{k}\left(m_{k} \otimes 1\right)+\sum \lambda_{i}\left(1 \otimes b_{i}\right)+\sum \mu_{j}\left(1 \otimes \xi_{j}\right)
$$

is a cocycle in $\boldsymbol{M}_{\mathbf{a}}$. Then -

$$
\sum v_{k} d m_{k}+\sum \mu_{j} x_{j}=0
$$

Since the classes $\left[x_{j}\right]$ are linearly independent, all $\mu_{j}=0$. If in addition $z \in$ ker $H^{\boxed{ }} f$ ), then

$$
\sum v_{k} f\left(m_{k}\right)+\sum \lambda_{i} b_{i}=0 .
$$

Since the $\left[b_{l}\right]$ form a basis of the cokernel of $H^{q}(f): H^{q}\left(\mu_{q-1}\right) \rightarrow H^{q}(A)$, all $\lambda_{i}=0$. Therefore, all the cocycles in $\mathcal{M}_{4}$ that map to zero come from $\boldsymbol{H}_{4-1}$, By the induction hypothesis these cocycles are exact. This proves the injeco tivity. The surjectivity follows directly from the definition of the $b_{i}$.

Finally, because $\boldsymbol{N}_{\mathbf{- 1}}$ has nothing in dimension 1 , the elements of dimension $q+1$ in $\boldsymbol{N}_{\mathbf{t}-1} \otimes \Lambda\left(b_{i}, \xi_{j}\right)$ all come from $\boldsymbol{N}_{\mathbf{i}-1}$; i.e,
$\mathscr{M}_{q}^{q+1}=\mathscr{M}_{q-1}^{q+1} \otimes 1$. Hence ker $H^{q+1}(f)$ is spanned by $x_{j} \otimes 1$. Since all of these elements are exact in $\mathscr{M}_{q}$ (they are the differentials of $\left.1 \otimes \xi_{j}\right), H^{q+1}(f)$ is injective.

## The Main Theorem and Applications

We will not prove the main theorem stated below. For a discussion of the proof, see Sullivan [1] and [2] and Deligne, Griffiths, Morgan and Sullivan [1].

Theorem 19.5. Let $M$ be a simply connected manifold and $\mathscr{M}$ its minimal model. Then the dimension of the vector space $\pi_{q}(M) \otimes \mathbb{Q}$ is the number of generators of the minimal model $\mathscr{M}$ in dimension $q$.

To make this theorem plausible, we will say a few words about the computation of the rational cohomology of $M$. The idea is to compute it from the Postnikov towers of $M$, whose fibers are the Eilenberg-MacLane spaces $K\left(\pi_{q}, q\right)$. Now there are two things to remember about the rational cohomology of $K\left(\pi_{q}, q\right)$ :
(a) a free summand $\mathbb{Z}$ in $\pi_{q}$ contributes a generator of dimension $q$ to the rational cohomology $H^{*}\left(K\left(\pi_{q}, q\right) ; \mathbb{Q}\right)$;
(b) a finite summand in $\pi_{q}$ contributes nothing.

In other words, the rational cohomology of $K\left(\pi_{q}, q\right)$ is a free algebra with as many generators as the rank of $\pi_{q}$ (see 18.9 and 18.12). As far as the rational cohomology is concerned, then, the finite homotopy groups in the Postnikov towers have no effect. If the minimal model of $M$ is to be built step by step out of its Postnikov towers, it makes sense that a generator appears in the model precisely when a rational homotopy element is involved. Hence it is not unreasonable that the dimension of the rational homotopy group $\pi_{d}(M) \otimes \mathbb{Q}$ is equal to the number of generators of the minimal model in dimension $q$. However, to make these arguments precise, considerable technical details remain to be resolved. In fact, at this writing there is no truly satisfactory exposition of rational homotopy theory available.

From this theorem and Examples 19.1 and 19.2 we have again Serre's "result (18.22) that the homotopy groups of an odd sphere $S^{\text {n }}$ are torsion except in dimension $n$, where it is infinite cyclic; for an even sphere $S^{\mathbf{n}}$, the exceptional dimensions are $n$ and $2 n-1$.

Example 19.6. The wedge of the spheres $S^{n}$ and $S^{m}$ is the union of $S^{n}$ and $S^{m}$ with one point in common, written $S^{n} \vee S^{m}$. As an application of Sullivan's theory we will compute the ranks of the first few homotopy groups of $S^{2} \vee S^{2}$. Since $S^{2} \vee S^{2}$ has the same homotopy type as $R^{3}-P-Q$, where $P$
and $Q$ are two distinct points of $\mathbb{R}^{\mathbf{3}}$, it suffices to construct a minimal model $\boldsymbol{M}$ for $\Omega^{*}\left(\mathbb{R}^{3}-P-Q\right)$.

At this stage we exploit the geometry of the situation to coresruct two closed 2 -forms $\bar{x}$ and $\bar{y}$ on $\mathbb{R}^{3}-P-Q$ that generate the cohomology. $H_{D R}\left(\mathbb{R}^{3}-P-Q\right)$ and that satisfy

$$
\bar{x}^{2}=\tilde{x} \bar{y}=\bar{y}^{2}=0
$$

For this purpose choose small spheres $S_{P}$ and $S_{Q}$ about $P$ and $Q$ respectively. Let $\omega_{P}$ be a bump form of mass 1 concentrated near the north pole of $S_{P}$ and let $\omega_{Q}$ be a similar form about the south pole of $S_{Q}$. The projection from $P$ defines a natural map

$$
\pi_{P}: \mathbb{R}^{3}-P-Q \rightarrow S_{P}
$$

similarly the projection from $Q$ defines a map

$$
\pi_{Q}: \mathbb{R}^{3}-P-Q \rightarrow S_{Q}
$$

Then

$$
\bar{x}=\pi_{P}^{*} \omega_{P} \quad \text { and } \quad \bar{y}=\pi_{Q}^{*} \omega_{Q}
$$

are easily seen to have the desired properties.
The minimal model is now constructed in a completely algebraic way as follows. First of all, the minimal model $\mathscr{M}$ must have two generators $\boldsymbol{x}$ and $y$ in dimension 2 mapping to $\bar{x}$ and $\bar{y}$. To kill $x^{2}, x y$, and $y^{2}$, we need three generators $a, b, c$ in dimension 3 with (sec Figure 19.1)

$$
\begin{aligned}
d a & =x^{2} \\
d b & =x y \\
d c & =y^{2}
\end{aligned}
$$

The map $f: \mathscr{M} \rightarrow \Omega^{*}\left(\mathbb{R}^{\mathbf{3}}-P-Q\right)$ up to this point is given by $x \mapsto \bar{x}, y \mapsto \bar{y}$, $a, b, c \mapsto 0$.

The differentials of the elements in dimension 5 are

$$
\begin{aligned}
& d(a x)=x^{3} \\
& d(a y)=x^{2} y \\
& d(b x)=x^{2} y \\
& d(b y)=x y^{2} \\
& d(c x)=x y^{2} \\
& d(c y)=y^{3}
\end{aligned}
$$

Hence $d(a y-b x)=0$ and $d(b y-c x)=0$. To kill these two closed forms,

Figure 19.1
there must be two elements $e$ and $g$ in dimension 4 such that

$$
\begin{aligned}
& d e=a y-b x \\
& d g=b y-c x .
\end{aligned}
$$

To find the generators in dimension 5 we need to know the closed forms in dimension 6 . By looking at the differentials of all the elements in dimension 6:

$$
\begin{aligned}
& d(e x)=a x y-b x^{2} \\
& d(e y)=a y^{2}-b x y \\
& d(g x)=b x y-c x^{2} \\
& d(g y)=b y^{2}-c x y \\
& d(a b)=b x^{2}-a x y \\
& d(b c)=c x y-b y^{2} \\
& d(a c)=c x^{2}-a y^{2}
\end{aligned}
$$

Th is radily determined that $e x+a b, g y+b c$, and $e y+g x+a c$ are closed. Fince the existing elements of dimension 5 do not map to these, we need prese gencrators $p, q, r$ in dimemsion $S$ with

$$
\begin{aligned}
& d p=e x+a b \\
& d q=g y+b c \\
& d r=e y+g x+a c .
\end{aligned}
$$

The reader is invited to continue this process one step further and show that in dimension 6 there are six generators.

In summary the generators in dimensions $\leq 6$ are

| $\operatorname{dim}$ | 2 | 3 | 4 | 5 | 6 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| generators | $x, y$ | $a, b, c$ | $e, g$ | $p, q, r$ | $s, t, u, v, w, z$ |

By Sullivan's theorem the rank of $\pi_{d}\left(S^{2} \vee S^{2}\right)$ is

| $q$ | 1 | 2 | 3 | 4 | 5 | 6 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\operatorname{dim} \pi_{\Omega}\left(S^{2} \vee S^{2}\right) \otimes Q$ | 0 | 2 | 3 | 2 | 3 | 6 |

This agrees with Hilton's result on the homotopy groups of a wedge of spheres (Hilton [1]), since by Hilton's theorem

$$
\begin{aligned}
\pi_{d}\left(S^{2} \vee S^{2}\right)= & \pi_{d}\left(S^{2}\right)+\pi_{d}\left(S^{2}\right)+\pi_{d}\left(S^{3}\right)+\pi_{d}\left(S^{4}\right)+\pi_{d}\left(S^{4}\right) \\
& +\sum_{3 \text { coppes }} \pi_{d}\left(S^{5}\right)+\sum_{6 \text { copes }} \pi_{d}\left(S^{6}\right)+\pi_{q} \text { of spheres of dimension } \geq 7 .
\end{aligned}
$$

## CHAPTER IV.

## Characteristic Classes

After the excursion into homotopy theory in the previous chapter, we return now to the differentiable category. Thus in this chapter, in the absence of explicit qualifications, all spaces are smooth manifolds, all maps are smooth maps, and $H^{*}(X)$ denotes the de Rham cohomology.

In Section 6 we first encountered the Euler class of a $C^{\infty}$ oriented rank 2 vector bundle. It is but one of the many characteristic classes-that is, cohomology classes intrisically associated to a vector bundle. In its modern form the theory of characteristic classes originated with Hopf, Stiefel, Whitney, Chern, and Pontrjagin. It has since found many applications to topology, differential geometry, and algebraic geometry.

In its most rudimentary form the point of view towards the Chern classes really goes back to the old Italian algebraic geometers, but in Section 20 we recast it along the ideas of Grothendieck. We introduce in Section 21 the computational and proof technique known as the splitting principle. This is followed by the Pontrjagin classes, which may be considered the real analogue of the Chern classes. We also include an application to the embedding of manifolds.

In the final section the Chern classes are shown to be the only complex characteristic classes in the following sense: any natural transformation from the complex vector bundles to the cohomology ring is a polynomial in the Chern classes. An added dividend is a classification theorem for complex vector bundles. With its aid we fulfill an earlier promise (see the remark following Prop. 11.9) to show that the vanishing of the Euler class of an oriented sphere bundle does not imply the existence of a section.

For the Euler class of a rank 2 bundle we had in (6.38) an explicit formula in terms of the patching data on the base manifold M. Elegant as the Grothendieck approach to the Chern classes is, it is not directly linked to the geometry of $M$, for it gives no such patching formulas. In the concluding remarks to this chapter we describe without proof a recipe for
constructing the Chern classes of a complex vector bundle $\pi: E \rightarrow M$ out of the transition functions of $E$ and a partition of unity on $M$ relative to some trivializing good cover for $E$.

## §20 Chern Classes of a Complex Vector Bundle

In this section we will study the characteristic classes of a complex vector bundle. To begin with we define the first Chern class of a complex line bundle as the Euler class of its underlying real bundle. Applying the LerayHirsch theorem, we then compute the cohomology ring of the projectivization $P(E)$ of a complex vector bundle $E$ and define the Chern classes of $E$ in terms of the ring structure of $H^{*}(P(E))$. We conclude with a list of the main properties of the Chern classes.

## The First Chern Class of a Complex Line Bundle

Recall that a complex vector bundle of rank $n$ is a fiber bundle with fiber $\mathbb{C}^{n}$ and structure group $G L(n$. $C$ ). A complex vector bundle of rank 1 is also called a complex line bundle. Just as the structure group of a real vector bundle can be reduced to the orthogonal group $O(n)$, so by the Hermitian analogue of (6.4), the structure group of a rank $n$ complex vector bundle can be reduced to the unitary group $U(n)$. Every complex vector bundle $E$ of rank $n$ has an underlying real vector bundle $E_{\mathbf{R}}$ of rank $2 n$, obtained by discarding the complex structure on each fiber. By the isomorphism of $U(1)$ with $S O(2)$, this sets up a one-to-one correspondence between the complex line bundles and the oriented rank 2 real bundles. We define the first Chern class of a complex line bundle $L$ over a manifold $M$ to be the Euler class of its underlying real bundle $L_{R}: c_{1}(L)=e\left(L_{R}\right) \in H^{2}(M)$.

If $L$ and $L^{\prime}$ are complex line bundles with transition functions $\left\{g_{\alpha}\right\}$ and $\left\{g_{\alpha \beta}^{\prime}\right\}$,

$$
g_{\alpha \beta}, g_{\alpha \beta}^{\prime}: U_{\alpha} \cap U_{\beta} \rightarrow C^{\star}
$$

then their tensor product $L \otimes L^{\prime}$ is the complex line bundle with transition functions $\left\{g_{\alpha \beta} \cdot g_{\alpha \beta}^{\prime}\right\}$. By the formula (6.38) which gives the Euler class in terms of the transition functions, we have

$$
\begin{equation*}
c_{1}\left(L \otimes L^{\prime}\right)=c_{1}(L)+c_{1}(L) \tag{20.1}
\end{equation*}
$$

Let $L^{*}$ be the dual of $L$. Since the line bundle $L \otimes L^{*}=\operatorname{Hom}(L, L)$ has a nowhere vanishing section given by the identity map, $L \otimes L^{*}$ is a trivial bundle, By (20.1), $c_{1}(L)+c_{1}\left(L^{*}\right)=c_{1}\left(L \otimes L^{*}\right)=0$. Therefore,

$$
\begin{equation*}
c_{1}\left(L^{*}\right)=-c_{1}(L) . \tag{20.2}
\end{equation*}
$$

Example 20.3 (Tautological bundles on a projective space). Let $V$ be a complex vector space of dimension $n$ and $P(V)$ its projectivization:

$$
P(V)=\{1 \text {-dimensional subspaces of } V\} .
$$

On $P(V)$ there are several God-given vector bundles: the product bundle $\hat{V}=P(V) \times V$, the universal subbundle $S$, which is the subbundle of $\hat{V}$ defined by

$$
S=\{(\ell, v) \in P(V) \times V \mid v \in \ell\}
$$

and the universal quotient bundle $Q$, defined by the exact sequence

$$
\begin{equation*}
0 \rightarrow S \rightarrow \hat{V} \rightarrow Q \rightarrow 0 . \tag{20.4}
\end{equation*}
$$

The fiber of $S$ above each point $\ell$ in $P(V)$ consists of all the points in $\ell$, where $\ell$ is viewed as a line in the vector space $V$. The sequence (20.4) is called the tautological exact sequence over $P(V)$, and $S^{*}$ the hyperplane bundle.

Consider the composition

$$
\sigma: S G P(V) \times V \rightarrow V
$$

of the inclusion followed by the projection. The inverse image of any point $v$ is

$$
\sigma^{-1}(v)=\{(\ell, v) \mid v \in \ell\} .
$$

If $v \neq 0, \sigma^{-1}(v)$ consists of precisely one point $(\ell, v)$ where $\ell$ is the line through the origin and $v$; if $v=0$, then $\sigma^{-1}(0)$ is isomorphic to $P(V)$. Thus $S$ may be obtained from $V$ by separating all the lines through the origin in $V$. This map $\sigma: S \rightarrow V$ is called the blow-up or the quadratic transformation of of $V$ at the origin. Over the real numbers the blow-up of a plane may be pictured as the portion of a helicoid in Figure 20.1 with its top and bottom edges identified. Indeed, we may view the $(x, y)$-plane as being traced out by a horizontal line rotating about the origin. In order to separate these lines at the origin, we let the generating line move with constant velocity along the $z$-axis while it is rotating horizontally. The resulting surface in $\mathbf{R}^{\mathbf{3}}$ is a helicoid.

We now compute the cohomology of $P(V)$. Endow $V$ with a Hermitian metric and let $E$ be the unit sphere bundle of the universal subbundle $S$ :

$$
E=\{(\ell, v) \mid v \in \ell,\|v\|=1\} .
$$

Note that $\sigma^{-1}(0)$ is the zero section of the universal subbundle $S$. Since $S-\sigma^{-1}(0)$ is diffeomorphic to $V-\{0\}$, we see that $E$ is diffeomorphic to the sphere $S^{2 n-1}$ in $V$ and that the map $\pi: E \rightarrow P(V)$ gives a fibering

$$
\begin{array}{r}
S^{1} \rightarrow S^{2 n-1} \\
\downarrow \\
P(V)
\end{array}
$$

Figure 20.1
By a computation similar to (14.32), the cohomology ring $H^{*}(P(V)$ ) is seen to be generated by the Euler class of the circle bundle E, ie, the first Chern class of the universal subbundle $S$. It is customary to take $x=c_{1}\left(S^{*}\right)=$ $-c_{1}(S)$ to be the generator and write

$$
\begin{equation*}
H^{*}(P(V))=R[x] /\left(x^{n}\right), \quad \text { where } n=\operatorname{dim}_{c} V \tag{20.5}
\end{equation*}
$$

We define the Poincuré series of a manifold $M$ to be

$$
P_{X}(M)=\sum_{i=0}^{\infty} \operatorname{dim} H^{( }(M) t^{t}
$$

By (20.5) the Poincare series of the projective space $P(V)$ is

$$
P_{A}(P(V))=1+t^{2}+\cdots+t^{2(m-1)}=\frac{1-t^{2 m}}{1-t^{2}}
$$

The Projectivization of a Vector Bundle
Let $\rho: E \rightarrow M$ be a complex vector bundie with transition functions $g_{a f}$ : $U_{a} \cap U_{\beta} \rightarrow G L(n, C)$. We write $E_{p}$ for the fiber over $p$ and $P G L(n, C)$ for the projective general linear group $G L(n, C) /\{$ acalar matrices $\}$. The projectivization of $E, \pi: P(E) \rightarrow M$, is by definition the fiber bundle whoee fiber at a point $p$ in $M$ is the projective space $P\left(E_{\eta}\right)$ and whose transition functions $\bar{g}_{a f}: U_{a} \cap U_{B} \rightarrow P G L(m, C)$ are induced from $g_{d}$. Thus a point of $P(B)$ is a line $\ell_{p}$ in the fiber $E_{p}$.

As on the projectivization of a vector spece, on $P(E)$ there are several
tautological bundles: the pullback $\pi^{-1} E$, the universal subbundle $S$, and the universal quotient bundle $Q$.

$$
0 \rightarrow S \rightarrow \pi^{-1} E \rightarrow Q \rightarrow 0
$$

The pullback bundle $\pi^{-1} E$ is the vector bundle over $P(E)$ whose fiber at $\ell_{p}$ is $E_{p}$. When restricted to the fiber $\pi^{-1}(p)$ it becor.es the trivial bundle,

$$
\left.\pi^{-1} E\right|_{P(E)_{p}}=P(E)_{p} \times E_{p}
$$

since $\rho: E_{p} \rightarrow\{p\}$ is a trivial bundle. The universal subbundle $S$ over $P(E)$ is defined by

$$
S=\left\{\left(\ell_{p}, v\right) \in \pi^{-1} E \mid v \in \ell_{p}\right\} .
$$

Its fiber at $\ell_{p}$ consists of all the points in $\ell_{p}$. The universal quotient bundle $Q$ is determined by the tautological exact sequence

$$
0 \rightarrow S \rightarrow \pi^{-1} E \rightarrow Q \rightarrow 0 .
$$

Set $x=c_{1}\left(S^{*}\right)$. Then $\dot{x}$ is a cohomology class in $H^{2}(P(E))$. Since the restriction of the universal subbundle $S$ on $P(E)$ to a fiber $P\left(E_{p}\right)$ is the universal subbundle $\tilde{S}$ of the projective space $P\left(E_{p}\right)$, by the naturality property of the first Chern class (6.39), it follows that $c_{1}(\tilde{S})$ is the restriction of $x$ to $P\left(E_{p}\right)$. Hence the cohomology classes $1, x, \ldots, x^{n-1}$ are global classes on $P(E)$ whose restrictions to each fiber $P\left(E_{p}\right)$ freely generate the cohomology of the fiber. By the Leray-Hirsch theorem (5.11) the cuhomology $H^{*}(P(E))$ is a free modulc over $H^{*}(M)$ with basis $\left\{1, x_{5} \ldots, x^{n-1}\right\}$. So $x^{n}$ can be written uniquely as a linear combination of $1, x, \ldots, x^{n-1}$ with coefficients in $H^{*}(M)$; these coefficients are by definition the Chern classes of the complex vector bundle $E$ :

$$
\begin{equation*}
x^{n}+c_{1}(E) x^{n-1}+\cdots+c_{n}(E)=0, \quad c_{i}(E) \in H^{2 i}(M) \tag{20.6}
\end{equation*}
$$

In this equation by $c_{i}(E)$ we really mean $\pi^{*} c_{i}(E)$. We call $c_{i}(E)$ the ith Chern class of $E$ and

$$
c(E)=1+c_{1}(E)+\cdots+c_{n}(E) \in H^{*}(M)
$$

its total Chern class. With this definition of the Chern classes, we see that the ring structure of the cohomology of $P(E)$ is given by

$$
\begin{equation*}
H^{*}(P(E))=H^{*}(M)[x] /\left(x^{n}+c_{1}(E) x^{n-1}+\cdots+c_{n}(E)\right), \tag{20.7}
\end{equation*}
$$

where $x=c_{1}\left(S^{*}\right)$ and $n$ is the rank of $E$. Since additively

$$
H^{*}(P(E))=H^{*}(M) \otimes H^{*}\left(P^{n-1}\right)
$$

the Poincare series of $P(E)$ is

$$
\begin{equation*}
P_{n}(P(E))=P_{s}(M) \frac{1-t^{2 n}}{1-t^{2}} \tag{20.8}
\end{equation*}
$$

We now have two definitions of the first Chern class of a line bundle $L$ : as the Euler class of $L_{\mathbb{R}}$, and as a coefficient in (20.6). To check that these two definitions agree we will temporarily reserve the notation $c_{1}()$ for the second definition. What must be shown is that $e\left(L_{R}\right)=c_{1}(L)$.

For a line bundle $L, P(L)=M, \pi^{-1} L=L$ and the universal subbundle $S$ on $P(L)$ is $L$ itself. Therefore, $x=e\left(S_{k}^{\phi}\right)=-e\left(S_{R}\right)=-e\left(L_{\mathbb{R}}\right)$. So the relation (20.6) is $x+e\left(L_{R}\right)=0$, which proves that $c_{1}(L)=e\left(L_{R}\right)$.

If $E$ is the trivial bundle $M \times V$ over $M$, then $P(E)=M \times P(V)$, so $x^{n}=0$. Hence all the Chern classes of a trivial bundle are zero. In this sense the Chern classes measure the twisting of a complex vector bundle.

## Main Properties of the Chern Classes

In this section we collect together some basic properties of the Chern classes.
(20.10.1) (Naturality) If $f$ is a map from $Y$ to $X$ and $E$ is a complex vector bundle sver $X$, then $c\left(f^{-1} E\right)=f^{*} c(E)$.

Proof. Basically this property follows from the functoriality of all the constructions in the definition of the Chern class. To be precise, by (6.39) the first Chern class of a line bundle is functorial. Write $S_{E}$ for the universal subbundle over $P E$. Now $f^{-1} P E=P\left(f^{-1} E\right)$ and $f^{-1} S_{E}^{*}=S_{f-1 E}^{\prime}$, so if $x_{E}=c_{1}\left(S_{E}^{z}\right)$, then

$$
x_{f-1 E}=c_{1}\left(S_{f-1 E}^{*}\right)=c_{1}\left(f^{-1} S_{E}^{*}\right)=f^{*} x_{E}
$$

Applying $f^{*}$ to

$$
x_{E}^{n}+c_{1}(E) x_{E}^{n-1}+\cdots+c_{n}(E)=0
$$

we get

$$
x_{f-1 E}^{n}+f^{*} c_{1}(E) x_{f-1 E}^{n-1}+\cdots+f^{*} c_{N}(E)=0 .
$$

Hence

$$
c_{1}\left(f^{-1} E\right)=f^{*} c_{1}(E)
$$

It follows from the naturality of the Chern class that if $E$ and $F$ are isomorphic vector bundles over $X$, then $c(E)=c(F)$.
(20.10.2) Let $V$ be a complex vector space. If $S^{*}$ is the hyperplane bundle over $P(V)$, then $c_{1}\left(S^{*}\right)$ generates the algebra $H^{*}(P(V))$.
This was proved earlier (20.5).
(20.10.3) (Whitney Product Formula) $c\left(E^{\prime} \oplus E^{\prime \prime}\right)=\alpha\left(E^{\prime}\right) c\left(E^{\prime \prime}\right)$.

The proof will be given in the next section.
In fact, these three properties uniquely characterize the Chern class (Hirzebruch [1, pp. 58-60]). For future reference we list below three more useful properties.
(20.10.4) If $E$ has rank $n$ as a complex vector bundle, then $c_{i}(E)=0$ for $i>n$. This is really a definition.
(20.10.5) If $E$ has a nonvanishing section, then the top Chern class $c_{N}(E)$ is zero.

Proof. Such a section $s$ induces a section $\tilde{s}$ of $P(E)$ as follows. At a point $p$ in $X$, the value of $\tilde{\tilde{s}}$ is the line in $E_{p}$ through the origin and $s(p)$.

$$
\begin{gathered}
P(E) \\
s|\mid \pi \\
X
\end{gathered}
$$

Then $\tilde{s}^{-1} S_{E}$ is a line bundle over $X$ whose fiber at $p$ is the line in $E_{p}$ spanned by $s(p)$. Since every line bundle with a nonvanishing section is isomorphic to the trivial bundle, we have the tautology

$$
5^{-1} S_{E} \simeq \text { the trivial line bundle. }
$$

It follows from the naturality of the Chern class that

$$
s^{*} c_{1}\left(S_{\mathrm{E}}\right)=0,
$$

which implies that

$$
s^{*} x=0
$$

Applying $\mathbf{s}^{*}$ to

$$
x^{n}+c_{1} x^{n-1}+\cdots+c_{n}=0
$$

we get

$$
s^{*} c_{n}=0
$$

By our abuse of notation this really means $\boldsymbol{s}^{\boldsymbol{*}} \boldsymbol{\pi}^{\boldsymbol{*}} c_{n}=0$. Therefore $c_{n}=0$.
(20.10.6) The top Chern class of a complex vector bundle $E$ is the Euler class of its realization :

$$
c_{\infty}(E)=e\left(E_{a}\right), \quad \text { where } n=\operatorname{rank} E .
$$

This proposition will be proved in the next section after we have established the splitting principle.

## §21 The Splitting Principle and Flag Manifolds

In this section we prove the Whitney product formula and compute a few Chern classes. The proof and the computations are based on the splitting principle, which, roughly speaking, states that if a polynomial identity in the Chern classes holds for direct sums of line bundles, then it holds for general vector bundles. In the course of establishing the spliting principle we introduce the flag manifolds. We conclude by computing the cohomology ring of a flag manifold.

## The Splitting Principle

Let $\tau: E \rightarrow M$ be a $C^{\infty}$ complex vector bundie of rank $n$ over a manifold $M$. Our goal is to construct a space $F(E)$ and a map $\sigma: F(E) \rightarrow M$ sych that:
(1) the pullback of $E$ to $F(E)$ splits into a direct sum of line bundles: $\sigma^{-1} E=L_{1} \oplus \cdots \oplus L_{n} ;$
(2) $\sigma^{*}$ embeds $H^{*}(M)$ in $H^{*}(F(E))$.

Such a space $F(E)$, which is in fact a manifold by construction, is called a split monnifoll of $E$.

If $E$ has rank 1 , there is nothing to prove.
If $E$ has rank 2, we can take as a split manifold $F(E)$ the projective
bundle $P(E)$, for on $P(E)$ there is the exact sequence

$$
0 \rightarrow S_{E} \rightarrow \sigma^{-1} E \rightarrow Q_{E} \rightarrow 0
$$

by the exercise below, $\sigma^{-1} E=S_{E} \oplus Q_{E}$, which is a direct sum of line bundle's.

Exercise 21.1. Let $0 \rightarrow A \rightarrow B \rightarrow C \rightarrow 0$ be a short exact sequence of $C^{\infty}$ complex vector bundles. Then $B$ is isomorphic to $A \oplus C$ as $C^{\infty}$ a bundle.

Now suppose $E$ has rank 3. Over $P(E)$ the line bundle $S_{E}$ splits off as before. The quotient bundle $Q_{E}$ over $P(E)$ has rank 2 and so can be split into a direct sum of line bundles when pulled back to $P\left(Q_{E}\right)$.

Thus we may take $P\left(Q_{E}\right)$ to be a split manifold $F(E)$. Let $x_{1}=\beta^{*} c_{1}\left(S_{E}^{*}\right)$ and $x_{2}=c_{1}\left(S_{0_{5}}^{*}\right)$. By the result on the cohomology of a projective bundle (20.7),

$$
\begin{gathered}
H^{*}(F(E))=H^{*}(M)\left[x_{1}, x_{2}\right] /\left(x_{1}^{3}+c_{1}(E) x_{1}^{2}+c_{2}(E) x_{1}+c_{3}(E)\right. \\
\left.x_{2}^{2}+c_{1}\left(Q_{E}\right) x_{2}+c_{2}\left(Q_{E}\right)\right) .
\end{gathered}
$$

The pattern is now clear; we split off one subbundle at a time by pulling back to the projectivization of a quotient bundle.

$$
\begin{equation*}
S_{1} \oplus \cdots \oplus S_{n-2} \oplus S_{n-1} \oplus Q_{n-1} \tag{21.2}
\end{equation*}
$$

So for a bundle $E$ of any rank $n$, a split manifold $F(E)$ exists and is given explicitly by (21.2). Its cohomology $H^{*}(F(E))$ is a free $H^{*}(M)$-module having as a basis all monomials of the form

$$
\begin{gather*}
x_{1}^{a_{1}} x_{2}^{a_{2}} \cdots x_{n-1}^{a_{n-1}}, a_{1} \leq n-1, a_{2} \leq n-2, \ldots, a_{n-1} \leq 1,  \tag{21.3}\\
a_{1}, \ldots, a_{n-1} \text { nonnegative, }
\end{gather*}
$$

where $x_{i}=c_{1}\left(S_{i}^{*}\right)$ in the notation of the diagram.
More generally, by iterating the construction above we see that given any number of vector bundles $E_{1}, \ldots, E_{r}$ over $M$, there is a manifold $N$ and a map $\sigma: N \rightarrow M$ such that the pullbacks of $E_{1}, \ldots, E_{r}$ to $N$ are all direct sums of line bundles and that $H^{*}(M)$ injecte into $H^{*}(N)$ under $\sigma^{*}$. The manifold $N$ is a split manifold for $E_{1}, \ldots, E_{r}$.

Because of the existence of the split manifolds we can formulate the following general principle

The Splitting Principle. To prove a polynomial identity in the Chern classes of complex vector bundles, it suffices to prove it under the assumption that the vector bundles are direct sums of line bundles.

For example, suppose we want to prove a certain polynomial relation $P(c(E), c(F), c(E \otimes F))=0$ for vector bundles $E$ and $F$ over a manifold $M$. Let $\sigma: N \rightarrow M$ be a split manifold for the pair $E, F$. By the naturality of the Chern classes

$$
\sigma^{*} P(c(E), c(F), c(E \otimes F))=P\left(c\left(\sigma^{-1} E\right), c\left(\sigma^{-1} F\right), c\left(\left(\sigma^{-1} E\right) \otimes\left(\sigma^{-1} F\right)\right)\right),
$$

where $\sigma^{-1} E$ and $\sigma^{-1} F$ are direct sums of line bundles. $S r$, if the identity holds for direct sums of line bundles, then

$$
\sigma^{*} P(c(E), c(F), c(E \otimes F))=0 .
$$

By the injectivity of $\sigma^{*}: H^{*}(M) \rightarrow H^{*}(N)$,

$$
P(c(E), c(F), c(E \otimes F))=0 .
$$

In the next two subsections we give some illustrations of this principle.

## Proof of the Whitney Product Formula and the Equality of the Top. Chern Class and the Euler Class

We consider first the case of a direct sum of line bundles:

$$
E=L_{1} \oplus \cdots \oplus L_{n} .
$$

By abuse of notation we write $\pi^{-1} E=L_{1} \oplus \cdots \oplus L_{n}$ for the pullback of $E$
to the projectivization $P(E)$. Over $P(E)$, the universal subbundle $S$ splits off from $\pi^{-1} E$.

Let $s_{i}$ be the projection of $S$ onto $L_{i}$. Then $s_{i}$ is a section of $\operatorname{Hom}\left(S, L_{i}\right)=$ $S^{*} \otimes L_{i}$. Since at every point $y$ of $P(E)$, the fiber $S$, is a 1 -dimensional subspace of $\left(\pi^{-2} E\right)_{\text {, }}$, the projections $s_{1}, \ldots, s_{n}$ cannot be simultaneously zero. It follows that the open sets

$$
U_{i}=\left\{y \in P(E) \mid s_{i}(y) \neq 0\right\}
$$

form an open cover of $P(E)$. Over each $U_{i}$ the bundle $\left.\left(S^{*} \otimes L_{i}\right)\right|_{U_{1}}$ has a nowhere-vanishing section, namely $s_{i} ;$ so $\left(S^{*} \otimes L_{i}\right) \mid v_{i}$ is trivial. Let $\xi_{i}$ be a closed global 2 -form on $P(E)$ representing $c_{1}\left(S^{*} \otimes L_{i}\right)$. Then $\xi_{i \mid U_{i}}=d \omega_{i}$ for some 1 -form $\omega_{i}$ on $U_{i}$. The crux of the proof is to find a global form on $P(E)$ that represents $c_{1}\left(S^{*} \otimes L_{i}\right)$ and that vanishes on $U_{i}$; because $\omega_{i}$ is not a global form on $P(E), \xi_{1}-d \omega_{i}$ won't do. However, by shrinking the open cover $\left\{U_{i}\right\}$ slightly we can extend $\xi_{i}-d \omega_{i}$ to a global form. To be precise we will need the following lemmas.

Exercise 21.4 (The Shrinking Lemma). Let $X$ be a normal topological space and $\left\{U_{i}\right\}_{i \in I}$ a finite open cover of $X$. Then there is an open cover $\left\{V_{i}\right\}_{i \in I}$ with

$$
\bar{V}_{i} \subset U_{i} .
$$

Exercise 21.5. Let $M$ be a manifold, $U$ an open subset, and $A$ a closed subset contained in $U$. Then there is a $C^{\infty}$ function $f$ which is identically 1 on $A$ and is 0 outside $U$.

It follows from these two lemmas that on $P(E)$ there exits an open cover $\left\{V_{i}\right\}$ and $C^{\infty}$ functions $p_{l}$ satisfying
(a) $\vec{V}_{i} \subset U_{i}$
(b) $\rho_{i}$ is 1 on $\bar{V}_{i}$ and is 0 outside $U_{i}$.

Now $\rho_{i} \omega_{i}$ is a giobal form which agrees with $\omega_{i}$ on $V_{i}$ so that

$$
\xi_{1}-d\left(\rho_{i} \omega_{i}\right)
$$

is a slobal fori幺 representing $c_{1}\left(S^{*} \otimes L_{i}\right)$ and vanishing on $V_{i}$. In summary,
there is an open cover $\left\{V_{i}\right\}$ of $P(E)$ such that $c_{1}\left(S^{*} \otimes L_{i}\right)$ may be represented by a global form which vanishes on $V_{i}$.

Since $\left\{V_{i}\right\}$ covers $P(E), \prod_{i=1}^{n} c_{1}\left(S^{*} \otimes L_{i}\right)=0$. Writing $x=c_{1}\left(S^{*}\right)$, this gives by (20.1)

$$
\prod_{i=1}^{n}\left(x+c_{1}\left(L_{i}\right)\right)=x^{n}+\sigma_{1} x^{n-1}+\cdots+\sigma_{n}=0
$$

where $\sigma_{i}$ is the $i$ th elementary symmetric polynomial of $c_{1}\left(L_{1}\right), \ldots, c_{1}\left(L_{n}\right)$. But this equation is precisely the defining equation of $c(E)$. Thus

$$
\sigma_{i}=c_{i}\left(E^{)}\right.
$$

and

$$
c(E)=\Pi\left(1+c_{1}\left(L_{i}\right)\right)=\Pi c\left(L_{1}\right) .
$$

So the Whitney product formula holds for a direct sum of line bundles. By the splitting principle it holds for any complex vector bundle. As an illustration of the splitting principle we will go through the argument in detail. Let $E$ and $E^{\prime}$ be two complex vector bundles of rank $n$ and $m$ respectively and let $\pi: F(E) \rightarrow M$ and $\pi^{\prime}: F\left(\pi^{-1} E^{\prime}\right) \rightarrow F(E)$ be the splitting constructions. Both bundles split completely when pulled back to $F\left(\pi^{-1} E^{\prime}\right)$ as indicated in the diagram below.

Let $\sigma=\pi^{\prime} \circ \pi$. Then

$$
\begin{aligned}
\sigma^{*} c\left(E \oplus E^{\prime}\right) & =c\left(\sigma^{-1}\left(E \oplus E^{\prime}\right)\right)=c\left(L_{1} \oplus \cdots \oplus L_{n} \oplus L_{1}^{\prime} \oplus \cdots \oplus L_{m}^{\prime}\right) \\
& =\prod c\left(L_{i}\right) c\left(L_{i}^{\prime}\right) \\
& =\sigma^{*} c(E) c^{*}\left(E^{\prime}\right)=\sigma^{*} c(E) c\left(E^{\prime}\right)
\end{aligned}
$$

Since $\sigma^{*}$ is injective, $c\left(E \oplus E^{\prime}\right)=c(E) c\left(E^{\prime}\right)$. This concludes the proof of the Whitney product formula.

Remark 21.6. By Exercise (21.1) and the Whitney product formula, whenever we have an exact sequence of $C^{\infty}$ complex vector biundles

$$
0 \rightarrow A \rightarrow B \rightarrow C \rightarrow 0,^{\prime}
$$

then $c(B)=C(A) c(C)$.

As an application of the existence of the split manifold and the Whitney product formula, we will prove now the relation (20.10.6) between the top Chern class and the Euler class. Let $E$ be a rank $n$ complex vector bundle and $\sigma: F(E) \rightarrow E$ its split manifold. Write $\sigma^{-1} E=L_{1} \oplus \cdots \oplus L_{n}$, where the $L_{i}$ 's are line bundles on the split manifold $F(E)$.

$$
\begin{aligned}
& \sigma^{*} c_{\infty}^{*}(E)=c_{\omega}\left(\sigma^{-1} E\right) \\
& =c_{1}\left(L_{1}\right) \cdots c_{1}\left(L_{2}\right) . \\
& =e\left(\left(L_{1}\right) a\right) \cdots e\left(\left(L_{n}\right)\right. \\
& =e\left(\left(L_{1}\right)_{n} \oplus \cdots \oplus\left(L_{n}\right)\right. \\
& =e\left(\left(\sigma^{-1} E\right),\right. \\
& =\sigma^{*}\left(E_{0}\right) . \\
& \text { by the naturality of } c_{n} \\
& \text { by the Whitney product formula } \\
& \text { (20.10.3) } \\
& \text { by the definition of the first Chern } \\
& \text { class of a complex line bundle } \\
& \text { by the Whitney product formula for } \\
& \text { the Euler class (12.5) }
\end{aligned}
$$

By the injectivity of $\sigma^{*}$ on cohomology, $c_{m}(E)=e\left(E_{R}\right)$.

## Computation of Some Chern Classes

Given a rank n complex vector bundle $\boldsymbol{E}$ we may write formally

$$
c(E)=\prod_{i=1}^{n}\left(1+x_{i}\right)
$$

where the $x_{i}$ 's may be thought of as the first Chern class of the line bundles into which $E$ splits when pulled back to the splitting manifold $F(E)$. Since the Chern classes $c_{1}(E), \ldots, c_{N}(E)$ are the elementary symmetric functions of $x_{1}, \ldots, x_{n}$, by the symmetric function theorem (van der Waerden [1, p. 99]) any symmetric polynomial in $x_{1}, \ldots, x_{n}$ is a polynomial in $c_{1}(E), \ldots, c_{N}(E)$; a similar result holds for power series.

Example 21.7 (Exterior powers, symmetric powers, and tensor products). Recall that if $V$ is a vector space with basis $\left\{v_{1}, \ldots, v_{n}\right\}$, then the exterior power $\Lambda^{P} V$ is the vector space with basis $\left\{v_{i_{1}} \wedge \cdots \wedge v_{i_{p}}\right\}_{1 \leqslant i_{1}<\ldots<i_{p} \leqslant n}$. So if $E$ is the direct sum of line bundies $E=L_{1} \oplus \cdots \oplus L_{n}$, then

$$
\Lambda^{P} E=\underset{1 \leqslant i_{1}<\cdots<\zeta_{6} \leqslant n}{\bigoplus}\left(L_{i_{1}} \otimes \cdots \otimes L_{1}\right)
$$

Hence

$$
\begin{aligned}
c\left(\Lambda^{P} E\right) & =\prod\left(1+c_{1}\left(L_{n_{1}} \otimes \cdots \otimes L_{i_{2}}\right)\right) & & \text { by the Whitney. product formula } \\
& =\prod\left(1+x_{i_{2}}+\cdots+x_{L_{1}}\right) & & \text { by }(20.1), \text { with } x_{i}=c_{1}\left(L_{i}\right),
\end{aligned}
$$

where the product is over all multi-indices $1 \leqslant i_{1}<\cdots<i_{n} \leqslant n$. Sirsce the right-hand side is symmetric in $x_{1}, \ldots, x_{n}$, it is expreasible as a polymon',
$Q$ in $c_{1}(E), \ldots, c_{\infty}(E), 80$

$$
c\left(\Lambda^{P} E\right)=Q\left(c_{1}(E), \ldots, c_{\infty}(E)\right)
$$

By the splitting principle this formula holds for every rank $n$ vector bundle, whether it is a direct sum or not. It should be pointed out that the polynomial $Q$ depends only on $n$ and $p$, not on $E, f$ fosesample, the Chern class of $\Lambda^{2} E$, where rank $E=3$, is given by ${ }^{-}$

$$
\begin{aligned}
c\left(\Lambda^{2} E\right)=Q\left(c_{1}, c_{2}, c_{3}\right) & =\left(1+c_{1}-x_{1}\right)\left(1+c_{1}-x_{2}\right)\left(1+c_{1}-x_{3}\right) \\
& =\left(1+c_{1}\right)^{3}-c_{1}\left(1+c_{1}\right)^{2}+c_{2}\left(1+c_{1}\right)-c_{3} .
\end{aligned}
$$

Similarly, if $V$ and $W$ are vector spaces with bases $\left\{v_{1}, \ldots, v_{n}\right\}$ and $\left\{w_{1}, \ldots\right.$, $\left.w_{m}\right\}$ respectively, then the pth symmetric power $S^{\rho} V$ of $V$ is the vector space with basis $\left\{v_{i_{1}} \otimes \cdots \otimes v_{i_{n}}\right\}_{1<i_{1} \leqslant \cdots \leqslant i_{5} \leqslant a}$ and the tensor product $V \otimes W$ is the vector space with basis $\left\{v_{i} \otimes w_{j}\right\}_{1 \leqslant 1 \leqslant m, 1 \leqslant j \leqslant m}$. By the same discussion as above, if $E$ is a rank $n$ vector bundle with $\alpha(E)=\prod_{i=1}\left(1+x_{1}\right)$ and $F$ is a rank $m$ vector bundle with $c(F)=\prod_{=1}\left(1+y_{j}\right)$, then

$$
\begin{equation*}
c\left(S^{P} E\right)=\prod_{1 \leqslant i_{1} \leqslant \cdots \leqslant i_{p} \leqslant n}\left(1+x_{i_{1}}+\cdots+x_{1}\right) \tag{21.8}
\end{equation*}
$$

and

$$
\begin{equation*}
d(E \otimes F)=\prod_{\substack{1<i<m \\ 1<j \leqslant m}}\left(1+x_{1}+y_{j}\right) \tag{21.9}
\end{equation*}
$$

In particular if $L$ is a complex line bundle with first Chern class $y_{y}$.then

$$
\begin{equation*}
d(E \otimes L)=\prod_{i=1}^{n}\left(1+y+x_{i}\right)=\sum_{i=0}^{n} c_{i}(E)(1+y)^{n-i} \tag{21.10}
\end{equation*}
$$

where by convention we et $c_{0}(E L)=1$.
Example 21.11 (The L-class and the Todd class). In the notation of the preceding example the power series

$$
\prod_{i=1}^{n} \frac{\sqrt{x_{i}}}{\tanh \sqrt{x_{i}}}
$$

is symmetric in $x_{1}, \ldots, x_{n}$, hence is some power series $L$ in $c_{1}(E), \ldots, c_{n}(E)$. This power series $L(E)=L\left(c_{1}(E), \ldots, c_{\mu}(E)\right)$ is called the $L$-class of $E$. By the splitting principle the $L$-class automatically satisfics the product formula

$$
\mu(E \oplus F)=\mu(E) L(P)
$$

Similarly,

$$
\prod_{i=1}^{n} \frac{x_{1}}{1-e^{x_{1}}}=\operatorname{Td}\left(c_{1}(E), \ldots, c_{\alpha}(E)\right)=\operatorname{Td}(E)
$$

defines the Told class of E. By the splitting principle the Todd class also automatically satisfies the product formula. The $L$-class and the Todd
class turn out to be of fundamental importance in the Hirzebruch signature formula (see Remark 22.9) and the Riemann-Roch theorem (see Hirzebruch [1]).

Example 21.12 (The dual bundle). Let $L$ be a complex line bundle. By (20.2),

$$
c_{1}\left(L^{*}\right)=-c_{1}(L) .
$$

Next consider a direct sum of line bundles

$$
E=L_{1} \oplus \cdots \oplus L_{n} .
$$

B: tho Whe rey product formula

$$
c^{\prime}(E)-c\left(L_{1}\right) \cdots c\left(L_{n}\right)=\left(1+c_{1}\left(L_{1}\right)\right) \cdots\left(1+c_{1}\left(L_{N}\right)\right) .
$$

On the other haud

$$
E^{*}=\dot{L}_{i}^{*} \oplus \cdots \oplus L_{n}^{*}
$$

and

$$
c\left(E^{*}\right)=\left(1-c_{1}\left(L_{1}\right)\right) \cdots\left(1-c_{1}\left(L_{N}\right)\right) .
$$

Therefore

$$
c_{d}\left(E^{*}\right)=(-1)^{\wedge} c_{d}(E) .
$$

By the splitting principle this result holds for all complex vector bundles $E$.
Example 21.13 (The Chern classes of the complex projective space). By analogy with the definition of a differentiable manifold, we say that a second countable, Hausdorff space $M$ is a complex manifold of dimension $n$ if every point has a neighborhood $U_{a}$ homeomorphic to some open ball in $C_{n}, \phi_{a}: U_{k} \rightarrow C^{n}$, such that the transition functions

$$
g_{a p}=\phi_{k} \cdot \phi_{\beta}^{-1}: \phi_{\phi}\left(U_{a} \cap U_{\beta}\right) \rightarrow C^{C^{n}}
$$

are holomorphic. Smooth maps and smooth vector bundles have obvious analogues in the holomorphic category. If $u_{1}, \ldots, u_{n}$ are the coordinate functions on $\mathrm{C}^{n}$, then $z_{i}=u_{i} \circ \phi_{a}, i=1, \ldots, n$, are the coordinate functions on $U_{a}$. At each point $p$ in $U_{a}$ the vectors $\partial / \partial z_{1}, \ldots, \partial / \partial z_{n}$ span over $C$ the holomorphic tangent bundle of $M$. It is a complex vector bundle of rank $n$. The Chern class of a complex manifold is defined to be the Chern class of its holomorphic tangent bundle.

The complex projective space CP ${ }^{\boldsymbol{*}}$ is an example of a complex manifold, since, as in Exercise 6.44, the transition functions $g_{j i}$ relative to the standard open cover are given by multiplication by $z_{i} / z_{j}$, which are holomorphic functions from $\phi_{i}\left(U_{i} \cap U_{j}\right)$ to $\phi_{j}\left(U_{1} \cap U_{j}\right)$. Recall that there is a tautological exact sequence on $C P^{m}$

$$
0 \rightarrow S \rightarrow \mathrm{C}^{n+1} \rightarrow Q \rightarrow 0
$$

where $\mathrm{C}^{\boldsymbol{n + 1}}$ denotes the trivial bundle of rank $n+1$ over $C P$. A tangent

Figure 21.1
vector to $C P^{n}$ at a line $\ell$ in $C^{n+1}$ may be regarded as an infinitenimat motion of the line $l$ (Figure 21.1). Such a motion corresponds to a limest map from $\ell$ to the quotient space $\mathrm{C}^{n+1} / \ell$, which may be represented by the complementary subspace of $\ell$ in $\mathrm{C}^{+1}$ (relative to some metric). Thus donoting the holomorphic tangent bundle by $T$, we have

$$
T \simeq \operatorname{Hom}(S, Q)=Q \otimes S^{\oplus}
$$

We will compute the Chern class of $T$ in two ways.
(1) Tensoring the tautological sequence with $S^{*}$, we get

$$
0 \rightarrow C \rightarrow S^{\star} \otimes C^{+1} \rightarrow S^{\dagger} \otimes Q \rightarrow 0
$$

By the Whitney product formula

$$
c(T)=c\left(S^{*} \otimes Q\right)=c\left(S^{*} \otimes C^{n+1}\right)=c\left(S^{*} \oplus \cdots \oplus S^{*}\right)=(1+x)^{n+1}
$$

where $x=c_{1}\left(S^{*}\right)$.
(2) From the tautological exact sequence and the Whitney product formmis

$$
G(Q)=\frac{1}{d(S)}=\frac{1}{1-x}=1+x+\cdots+x^{n}
$$

since $x^{n+1}=0$ in $H^{*}\left(C P^{m}\right)$. By (21.10)

$$
\begin{aligned}
C\left(C P^{n}\right)=c\left(Q \otimes S^{+}\right) & =\sum_{i=0}^{n} c\left(Q x(1+x)^{-1}=\sum_{i=0}^{n} x^{n}(1+x)^{n-1}\right. \\
& =(1+x)^{n} \sum_{i=0}^{n}\left(\frac{x}{1+x}\right)^{1} \\
& =(1+x)^{n}\left[\left(1-\left(\frac{x}{1+x}\right)^{n+1}\right) /\left(1-\frac{x}{1+x}\right)\right] \\
& =(1+x)^{n+1}\left[1-\left(\frac{x}{1+x}\right)^{n+1}\right] \\
& =(1+x)^{n+1}-x^{n+1} \\
& =(1+x)^{n+1}
\end{aligned}
$$

Exercise 21.14. Chern classes of a hypersurface in a complex projective space. Let $H$ be the hyperplane bundle over the projective space CP (see (20.3)), and $H^{\otimes k}$ the tensor product of $k$ copies of $H$. The line bundle $H$ is in fact more than a $C^{\infty}$ complex line bundle; because its transition functions are holomorphic, it is a holomorphic line bundle. The total space of a holomorphic bundle over a complex manifold is again a complex manifold, so that the notion of a holomorphic section makes sense. The zero locus of a holomorphic section of $H^{\infty k}$ is called a hypersurface of degree $k$ in $\mathbb{C} P^{n}$. If the section is transversal to the zero section, then the hypersurface is a smooth complex manifold. Compute the Chern classes of a smooth hypersurface of degree $k$ in $\mathbb{C P}^{\text {m }}$. (Hint: apply Prop. 12.7 to get the normal bundle of the hypersurface.)

## Flag Manifolds

Given a complex vector space $V$ of dimension $n$, a flay in $V$ is a sequence of subspaces $A_{1} \subset A_{2} \subset \cdots \subset A_{n}=V, \operatorname{dim}_{c} A=i$. Let $F l(V)$ be the collection of all flags in $V$. Clearly any flag can be carried into any other flag in $V$ by an element of the general linear group $G L(n, C)$, and the stabilizer at a flag is the group $H$ of the upper triangular matrices. So as a set $F l(V)$ is isomorphic to the coset space $G L(n, C) / H$. Since the quotient of a Lie group by a closed subgroup is a manifold (Warner [1, p. 120]), $F(V)$ can be made into a manifold. It is called the flag manifold of $V$.

Given a vector bundle $E$, just as one can form its projectivization $P(E)$, so one can form its associated flag bundle $F l(E)$. The bundle $F l(E)$ is obtained from $E$ by replacing each fiber $E_{0}$ by the flag manifold $F l\left(E_{p}\right)$; the local trivialization $\phi_{a}:\left.E\right|_{U_{a}} \leadsto U_{a} \times \mathbb{C}^{n}$ induces a natural trivialization $\left.F l(E)\right|_{U_{a}} \simeq U_{a} \times F l\left(\mathbb{C}^{n}\right)$. Since $G L(n, \mathbb{C})$ acts on $F l\left(\mathbb{C}^{n}\right)$, we may take the transition functions of $F l(E)$ to be those of $E$, but note that $F l(E)$ is not a vector bundle.

Propocition 21.15. The associated flag bundle $F((E)$ of a vector bundle is the split manifold $F(E)$ constructed earlier.

Proof. We first show this for $E=V$ a vector space of dimension 3, viewed as a rank 3 vector bundle over a point.

In what follows all lines and planes go through the origin. A point in $P(V)$ is a line $L$ in $V$. A point of $P\left(Q_{V}\right)$ is a line $L$ in $V$ and a line $L^{\prime}$ in $V / L$. $L^{\prime}$ may be regarded as a 2 -plane in $V$ containing $L$. Thus $F l(V)=$ $P\left(Q_{V}\right)=\left\{A_{1} \subset A_{2} \subset V, \operatorname{dim} A_{i}=i\right\}=F(V)$.

Now let $E$ be a vector bundle of rank $n$ over $M$. The split manifold $F(E)$ is obtained by a sequence of $n-1$ projectivizations as in (21.2). A point of $P(E)$ is a pair $(p, \ell)$, where $p$ is in $M$ and $\ell$ is a line in $E_{p}$. By introducing a Hermitian metric on $E$, we may regard all the quotient bundles $Q_{1}, \ldots$, $Q_{n-1}$ in (21.2) as subbundles of $E$. Then a point of $P\left(Q_{1}\right)$ over $\left(p, \ell_{1}\right)$ in $P(E)$ is a triple $\left(p, \ell_{1}, \ell_{2}\right)$ where $\ell_{2}$ is a line in the orthogonal complement of $\ell_{1}$ in $E_{p}$. A point of $P\left(Q_{2}\right)$ over $\left(p, \ell_{1}, \ell_{2}\right)$ in $P\left(Q_{1}\right)$ is a 4-tuple $\left(p, \ell_{1}, \ell_{2}, \ell_{3}\right)$ where $\ell_{3}$ is a line in the orthogonal complement of $\ell_{1}$ and $\ell_{2}$ in $E_{p}$. Thus, more generally, a point in the split manifold $F(E)=P\left(Q_{n-1}\right)$ may be identified with the flag

$$
\left(p, \ell_{1} \subset\left\{\ell_{1}, \ell_{2}\right\} \subset\left\{\ell_{1}, \ell_{2}, \ell_{3}\right\} \subset \cdots \subset E_{p}\right)
$$

This proves the equality of the split manifold $F(E)$ and the flag bundle $F(E)$.
From now on the notations $F(E)$ and $F l(E)$ will be used interchangeably.
The formula (21.3) gives one description of the vector space structure of the cohomology of a flag bundle. To compute its ring structure we first recall from (20.7) that if $E$ is a rank $n$ complex vector bundle over $M$, then the cohomology ring of its projectivization is

$$
H^{*}(P(E))=H^{*}(M)[x] /\left(x^{n}+c_{1}(E) x^{n-1}+\cdots+c_{d}(E)\right), \text { where } x=c_{1}\left(S^{*}\right)
$$

Notation. If $A$ is a polynomial ring, and $a, b, c, f \in A$, then ( $a, b, c$ ) denotes the ideal generated by $a, b$, and $c$, while $(f=0)$ the ideal generated by the homogeneous components of $f$.

There is an alternate description of the ring structure which is sometimes very useful. We write $H^{*}(M)[c(S), c(Q)]$ for $H^{*}(M)\left[c_{1}(S), c_{1}(Q), \ldots, c_{n-1}(Q)\right]$, where $S$ and $Q$ are the universal subbundle and quotient bundle on $P(E)$.

Proposition 21.16. $\left.H^{*}(P(E))=H^{*}(M)[d S), c(Q)\right] /\left(c(S) c(Q)=\pi^{*} c(E)\right)$.
Proof. The idea is to eliminate the feperators $c_{1}(Q), \ldots, c_{z-1}(Q)$ by using the relation $c(S) c(Q)=\pi^{*} c(E)$. Let $x=c_{1}\left(S^{*}\right) y_{1}=c_{d}(Q)$ and $c_{i}=\pi^{+} c_{(E)}$. Equating the terms of equal degrees in

$$
(1-x)\left(1+y_{1}+\cdots+y_{n-1}\right)=1,+c_{1}+\cdots+c_{n}
$$

we get

$$
\begin{gathered}
y_{1}-x=c_{1} \\
y_{2}-x y_{1}=c_{2} \\
y_{3}-x y_{2}=c_{3} \\
\vdots \\
y_{n-1}-x y_{n-2}=c_{n-1} \\
-x y_{n-1}=c_{n}
\end{gathered}
$$

By the first $n-1$ equations, $y_{1}, \ldots, y_{n-1}$ can be expressed in terms of $x$ and elements of $H^{*}(M)$, and so can be eliminated as generators of $H^{*}(M)[c(S), c(Q)] /\left(c(S) c(Q)=\pi^{*} c(E)\right)$. The last equation $-x y_{n-1}=c_{n}$ translates into
(*)

$$
x^{n}+c_{1} x^{n-1}+\cdots+c_{n}=0
$$

Hence $H^{*}(M)[c(S), c(Q)] /\left(c(S) c(Q)=\pi^{*} c(E)\right)$ is isomorphic to the polynomial ring over $H^{*}(M)$ with the single generator $x$ and the single relation (*).

By (21.2) and (21.15) the flag bundle $F l(E)$ is obtained from a sequence of $n-1$ projectivizations. Applying Proposition 21.16 to (21.2), we have

$$
\begin{aligned}
& H^{*}\left(P\left(Q_{1}\right)\right) \\
& \quad=H^{*}(P(E))\left[c\left(S_{2}\right), c\left(Q_{2}\right)\right] /\left(c\left(S_{2}\right) c\left(Q_{2}\right)=c\left(Q_{1}\right)\right) \\
&=H^{*}(M)\left[c\left(S_{1}\right), c\left(Q_{1}\right), c\left(S_{2}\right), c\left(Q_{2}\right)\right] /\left(c\left(S_{1}\right) c\left(Q_{1}\right)=c(E), c\left(S_{2}\right) c\left(Q_{2}\right)=c\left(Q_{1}\right)\right) \\
& \quad=H^{*}(M)\left[c\left(S_{1}\right), c\left(S_{2}\right), c\left(Q_{2}\right)\right] /\left(c\left(S_{1}\right) c\left(S_{2}\right) c\left(Q_{2}\right)=c(E)\right)
\end{aligned}
$$

By induction

$$
\begin{aligned}
& H^{*}\left(P\left(Q_{n-2}\right)\right) \\
& \quad=H^{*}(M)\left[c\left(S_{1}\right), \ldots, c\left(S_{n-1}\right), c\left(Q_{n-1}\right)\right] /\left(c\left(S_{1}\right) \cdots c\left(S_{n-1}\right) c\left(Q_{n-1}\right)=c(E)\right) .
\end{aligned}
$$

Writing $x_{i}=c_{1}\left(S_{i}\right), i=1, \ldots, n-1$, and $x_{n}=c\left(Q_{n-1}\right)$, the cohomology ring of the flag bundle $F l(E)$ is

$$
H^{*}\left((F l(E))=H^{*}(M)\left[x_{1}, \ldots, x_{n}\right] /\left(\prod_{i=1}^{n}\left(1+x_{i}\right)=c(E)\right)\right.
$$

Specializing this theorem to a complex vector space $V$, considered as the trivial bundle over a point, we obtain the cohomology ring of the flag manifold

$$
H^{*}\left((F l(V))=R\left[x_{1}, \ldots, x_{n}\right] /\left(\prod_{i=1}^{n}\left(1+x_{i}\right)=1\right)\right.
$$

As for the Poincare polynomial of the flag manifold we note again that the flag manifold is obtained by a sequence of $n-1$ projectivizations (21.2).

By (20.8) each time we projectivize a rank $k$ vector bundle, the Poincaré polynomial is multiplied by $\left(1-t^{2 k}\right) /\left(1-t^{2}\right)$. So the Poincare polynomial of the flag manifold $F l(V)$ is

$$
P_{t}(F l(V))=\frac{1-t^{2 n}}{1-t^{2}} \cdot \frac{1-t^{2 n-2}}{1-t^{2}} \cdots \cdot \frac{1-t^{2}}{1-t^{2}} .
$$

This discussion may be summarized in the following proposition.
Proposition 21.17. Let $V$ be a complex vector space of dimension $n$. The cohomology ring of the flag manifold $F(V)$ is

$$
H^{*}(F l(\dot{V}))=\mathbb{R}\left[x_{1}, \ldots, x_{n}\right] /\left(\prod_{i=1}^{n}\left(1+x_{i}\right)=1\right)
$$

It has Poincaré polynomial

$$
P_{त}(F l(V))=\frac{\left(1-t^{2}\right)\left(1-t^{4}\right) \cdots\left(1-t^{2 n}\right)}{\left(1-t^{2}\right)\left(1-t^{2}\right) \cdots\left(1-t^{2}\right)}
$$

Remark 21.18. Similarly, if $E$ is a rank $n$ complex vector bundle over a manifold $M$, then the cohomology ring of the fiag bundle $F(E)$ is

$$
H^{*}(F l(E))=H^{*}(M)\left[x_{1}, \ldots, x_{n}\right] /\left(\prod_{l=1}^{n}\left(1+x_{l}\right)=c(E)\right),
$$

and the Poincaré series is

$$
P_{N}\left(F l\left(E_{j}\right)=P_{d}(M) \frac{\left(1-t^{2}\right)\left(1-t^{4}\right) \cdots\left(1-t^{2 m}\right)}{\left(1-t^{2}\right)\left(1-t^{2}\right) \cdots\left(1-t^{2}\right)}\right.
$$

Remark 21.19. Since projectivization does not introduce any torsion element in integer cohomology, the integer cohomology ring of the flag manifold $F l(V)$ is torsion-free and is given by the same formula as (21.17) with $\mathbf{Z}$ in place of $\mathbb{R}$. The integer cohomology ring of a flag bundle is given by the same formula as (21.18). In fact, with a little care, the entire discussion can be translated into the Cech theory.

## §22 Pontrjagin Classes

Although the Chern classes are invariants of a complex bundle, they can be used to define invariants of a real vector bundle, called the Pontrjagin classes. In this section we define the Pontrjagin classes, compute a few examples, and as an application obtain an embedding criterion for differentiable manifolds.

## Conjugate Bundles

Let $V$ be a complex vector space. If $z \in \mathbb{C}$ and $v \in V$, the formula

$$
z * v=\bar{z} v
$$

defines an action of $\mathbb{C}$ on $V$. The underlying additive group of $V$ with this action as scalar multiplication is called the conjugate vector space of $V$, denoted $\bar{V}$. The conjugate space $\bar{V}$ may be thought of as $V$ with the opposite complex structure; as a vector space, $\bar{V}$ is anti-isomorphic to $V$. A linear map $f: V \rightarrow W$ of two complex vector spaces $V$ and $W$ is also a linear map of the conjugate vector spaces $f: \bar{V} \rightarrow \bar{W}$; we denote both by $f$ as they are represented by the same matrix.

Given a complex vector bundle $E$ with trivialization

$$
\phi_{a}:\left.E\right|_{U_{a}} \neq U_{a} \times \mathbb{C}^{n}
$$

we construct the conjugate vector bundle $\bar{E}$ by replacing each fiber of $E$ by its conjugate. The trivialization of $\vec{E}$ is given by

$$
\bar{\phi}_{\varepsilon}:\left.\bar{E}\right|_{U_{s}} \simeq U_{a} \times \mathbb{C}^{n}
$$

which is the composition

$$
\left.\bar{E}\right|_{U_{a}} \stackrel{\phi_{a}}{\mathcal{O}} U_{a} \times \overline{\mathbf{C}}^{n} \xrightarrow{\text { conjugation }} U_{a} \times \mathbb{C}^{n}
$$

In terms of transition functions, if the cocycle $\left\{g_{\alpha \beta}\right\}$ defines $E$, then its conjugate $\left\{\bar{g}_{a \beta}\right\}$ defines $\bar{E}$.

As in (6.4), by endowing a complex vector bundle on a manifold with a Hermitian metric, we can reduce its structure group to the unitary group. Since unitary matrices $g_{a \beta}$ satisfy $\tilde{g}_{a \beta}=\left(g_{a \beta}^{d}\right)^{-1}$, we see that the conjugate bundle $\bar{E}$ and the dual bundle $E^{*}$ have the same transition functions and hence are isomorphic. So by Example 21.12, if $c(E)=\Pi\left(1+x_{i}\right)$, then $c(E)=\prod\left(1-x_{i}\right)$.

## Realization and Complexification

By simply forgetting the complex structure, we can regard a linear map of complex vector spaces $L: \mathbb{C}^{n} \rightarrow \mathbb{C}^{n}$ with coordinates $z_{1}, \ldots, z_{n}$ as a linear map of the underlyi., real vector spaces $L_{\mathbf{R}}: \mathbf{R}^{2 n} \rightarrow \mathbf{R}^{2 n}$ with coordinates $x_{1}, \ldots, x_{2 n}$ where $z_{k}=x_{2 k-1}+i x_{2 k}$. Conversely, via the natural embedding of $\mathbf{R}^{n}$ in $\mathbb{C}^{n}$, a linear map of real vector spaces $L: \mathbf{R}^{n} \rightarrow \mathbf{R}^{n}$ gives rise to a $\operatorname{map} L \otimes \mathbb{C}: \mathbb{C}^{n} \rightarrow \mathbb{C}^{n}$. The first operation is called realization and the second, complexification. The complexification of a real matrix is the matrix itself, but with the entries viewed as complex numbers. The realization of a complex matrix is described in Examples 22.2 and 22.3 below. In terms of
matrices these tho operations give a sequence of embeddings

$$
U(n) \hookrightarrow \quad O(2 n) \quad \hookrightarrow U(2 n)
$$

$$
\begin{gather*}
G L(n, \mathbb{C}) \hookrightarrow G L(2 n, \mathbb{R}) \hookrightarrow G L(2 n, \mathrm{C})  \tag{22.1}\\
A \mapsto \quad A_{\mathbb{R}} \mapsto A_{\mathbb{R}} \otimes \mathrm{C} .
\end{gather*}
$$

Example 22.2. Let $L: \mathbb{C} \rightarrow \mathbb{C}$ be given by multiplication by the complex number $\lambda=\alpha+i \beta$. Since

$$
(\alpha+i \beta)\left(x_{1}+i x_{2}\right)=\left(\alpha x_{1}-\beta x_{2}\right)+i\left(\beta x_{1}+\alpha x_{2}\right)
$$

as a linear map from $\mathbb{R}^{2}$ to $R^{\prime}, L_{R}$ is given by

$$
\binom{x_{1}}{x_{2}} \mapsto\left(\begin{array}{rr}
\alpha & -\beta \\
\beta & \alpha
\end{array}\right)\binom{x_{1}}{x_{2}} .
$$

Thus

$$
(\alpha+i \beta)_{m}=\left(\begin{array}{rr}
\alpha & -\beta \\
\beta & \alpha
\end{array}\right)
$$

Example 22.3 Let $L: \mathbb{C}^{2} \rightarrow \mathbb{C}^{2}$ be given by the complex matrix $\left(\begin{array}{ll}\lambda_{1} & \lambda_{2} \\ \lambda_{3}\end{array}\right)$ where $\lambda_{k}=\alpha_{k}+i \beta_{k}$. A little computation shows that $L_{R}: \mathbf{R}^{4} \rightarrow \mathbf{R}^{4}$ is given by

$$
\left(\begin{array}{l}
x_{1} \\
x_{2} \\
x_{3} \\
x_{4}
\end{array}\right) \mapsto\left(\begin{array}{rrrr}
\alpha_{1} & -\beta_{1} & \alpha_{2} & -\beta_{2} \\
\beta_{1} & \alpha_{1} & \beta_{2} & \alpha_{2} \\
\alpha_{3} & -\beta_{3} & \alpha_{4} & -\beta_{4} \\
\beta_{3} & \alpha_{3} & \beta_{4} & \alpha_{4}
\end{array}\right)\left(\begin{array}{l}
x_{1} \\
x_{2} \\
x_{3} \\
x_{4}
\end{array}\right)
$$

Thus

$$
\left(\begin{array}{ll}
\lambda_{1} & \lambda_{2} \\
\lambda_{3} & \lambda_{4}
\end{array}\right)_{R}=\left(\begin{array}{ll}
\left(\lambda_{1}\right)_{R} & \left(\lambda_{2}\right)_{R} \\
\left(\lambda_{3}\right)_{R} & \left(\lambda_{4}\right)_{R}
\end{array}\right)
$$

It is clear from these two examples what the realization of an $n$ by $n$ complex matrix should be.

Lemma 22.4. Let $A$ be an $n$ by $n$ complex matrix. There is a $2 n$ by $2 n$ matrix $B$, independent of $A$, such that $A_{\mathbb{R}} \otimes C$ is similar to $\left(\begin{array}{cc}1 & 0 \\ 0 & 1\end{array}\right)$ via $B$.

Proof. In the 1 by 1 case, this is a matter of diagonalizing

$$
(\alpha+i \beta)_{Q} \otimes C=\left(\begin{array}{rr}
\alpha & -\beta \\
\beta & \alpha
\end{array}\right)
$$

Corresponding to the eigenvalues $\alpha+i \beta$ and $\alpha-i \beta$ are the eigenvectors $\binom{1}{-i}$ and $\binom{1}{1}$. Therefore, $B=\left(\begin{array}{ll}1 & 1 \\ -i & i\end{array}\right)$.

Now consider the 2 by 2 case:

$$
\begin{gathered}
A=\left(\begin{array}{ll}
\lambda_{1} & \lambda_{2} \\
\lambda_{3} & \lambda_{4}
\end{array}\right), \quad \lambda_{k}=\alpha_{k}+i \beta_{k} \\
A_{R} \otimes C=\left(\begin{array}{ll}
A_{1} & A_{2} \\
A_{3} & A_{4}
\end{array}\right) \text { where } A_{k}=\left(\begin{array}{cr}
\alpha_{k} & -\beta_{k} \\
\beta_{k} & \alpha_{k}
\end{array}\right) .
\end{gathered}
$$

Note that

$$
\begin{gathered}
\left(\begin{array}{ll}
A_{1} & A_{2} \\
A_{3} & A_{4}
\end{array}\right)\left(\begin{array}{r}
1 \\
-i \\
0 \\
0
\end{array}\right)=\left(\begin{array}{r}
\lambda_{1} \\
-i \lambda_{1} \\
\lambda_{3} \\
-i \lambda_{3}
\end{array}\right)=\left(\begin{array}{rrrl}
1 & 0 & * & * \\
-i & 0 & * & * \\
0 & 1 & * & * \\
0 & -i & * & *
\end{array}\right)\left(\begin{array}{l}
\lambda_{1} \\
\lambda_{3} \\
0 \\
0
\end{array}\right) \\
\left(\begin{array}{ll}
A_{1} & A_{2} \\
A_{3} & A_{4}
\end{array}\right)\left(\begin{array}{rrrr}
1 & 0 & 1 & 0 \\
-i & 0 & i & 0 \\
0 & 1 & 0 & 1 \\
0 & -i & 0 & i
\end{array}\right)=\left(\begin{array}{rrrr}
1 & 0 & 1 & 0 \\
-i & 0 & i & 0 \\
0 & 1 & 0 & 1 \\
0 & -i & 0 & i
\end{array}\right)\left(\begin{array}{llll}
\lambda_{1} & \lambda_{2} & \\
\lambda_{3} & \lambda_{4} & & \\
& & \bar{\lambda}_{1} & \bar{\lambda}_{2} \\
& & \bar{\lambda}_{3} & \lambda_{4}
\end{array}\right)
\end{gathered}
$$

So

$$
B=\left(\begin{array}{rrrr}
1 & 0 & 1 & 0 \\
-i & 0 & i & 0 \\
0 & 1 & 0 & 1 \\
0 & -i & 0 & i
\end{array}\right)
$$

For the $n$ by $n$ case, we can take $B$ to be

If $E$ is a complex vector bundle of rank $n$ with transition functions $\left\{g_{a \beta}\right\}$, then $E_{\mathbf{R}} \otimes C$ is the complex vector bundle of rank $2 n$ with transition functions $\left\{\left(g_{a f}\right)_{R} \otimes \mathbb{C}\right\}$. By Lemma 22.4,
(22.5)

$$
E_{R} \otimes C \simeq E \oplus \vec{E}
$$

This result may be seen alternatively as follows. On the complex vector space $E_{\mathbf{R}} \otimes \mathbb{C}$, multiplication by $i$ is a linear transformation $J$ satisfying $J^{2}=-1$. Therefore, the eigenvalues of $J$ are $\pm i$ and $E_{R} \otimes C$ accordingly decomposes into a direct sum

$$
E_{R} \otimes C=(i \text {-eigenspace }) \oplus((-i) \text {-eigenspace })
$$

On the $i$-eigenspace, $J$ acts as multiplication by $i$, hence

$$
(i \text {-eigenspace }) \supset E .
$$

Similarly,

$$
((-i) \text {-eigenspace }) \supset \bar{E} .
$$

It follows by reasons of dimension that

$$
E_{\boldsymbol{a}} \otimes \mathbb{C}=E \oplus \bar{E} .
$$

## The Pontrjagin Classes of a Real Vector Bundle

By their naturality property the Chern classes of a $C^{\infty}$ complex vector bundle are $C^{\infty}$ invariants of the bundle. For a real vector bundle $E$ similar invariants may be obtained by considering the Chern classes of its complexification $E \otimes_{R} \mathbb{C}$; these are the Pontrjagin classes of $E$. More preciecly, if $E$ is a rank $n$ real vector bundle over $M$, then its total Pontrjagin class is

$$
\begin{aligned}
p(E) & =1+p_{1}(E)+\cdots+p_{n}(E) \\
& =1+c_{1}(E \otimes \mathbb{C})+\cdots+c_{n}(E \otimes \mathbb{C}) \in H^{*}(M)
\end{aligned}
$$

It follows from the corresponding properties of the total Chern class that the Pontrjagin class is functorial and satisfies the Whitney product formula

$$
p\left(E \oplus E^{\prime}\right)=p(E) p\left(E^{\prime}\right)
$$

The Pontrjagin class of a manifold is defined to be that of its tangent bundle.

Remark 22.6. Let $E$ be a real vector bundle. Because the transition functions of $E \otimes C$ are the same as those of $E$, they are real-valued, and therefore $E \otimes C$ is isomorphic to its conjugate $E \otimes C$. It follows that $c_{i}(E \otimes \mathbb{C})=c_{i} \overline{(E \otimes C)}=(-1)^{i} c_{i}(E \otimes C)$. For an odd $i$, then, $2 c_{i}(E \otimes C)=0$. Thus the odd Pontrjagin classes, as we have defined them, are zero in the de Rham cohomology, and torsion of order 2 in the integral cohomology. The usual definition of the Pontrjagin classes in the literature (see, for instance, Milnor and Stasheff [1, p. 174]) ignores these odd Chern classes and defines $p_{l}(E)$ to be

$$
(-1)^{i} c_{2 i}(E \otimes \mathrm{C})
$$

Example 22.7. (The Pontrjagin class of the sphere). Since the sphere $S^{n}$ is orientable, its normal bundle $N$ in $\mathbb{R}^{n+1}$ is trivial. From the exact sequence

$$
\left.0 \rightarrow T_{S_{n}} \rightarrow T_{R_{n}+1}\right|_{S_{n}} \rightarrow N \rightarrow 0,
$$

we see by the Whitney product formula that

$$
p\left(S^{n}\right) p(N)=p\left(\left.T_{R_{n+1}}\right|_{S_{n}}\right) .
$$

Therefore,

$$
p\left(S^{\prime \prime}\right)=1
$$

Example 22.8 (The Pontrjagin class of a complex manifold). The Pontrjagin class of a complex manifold $M$ is defined to be that of the underlying real manifold $M_{\mathbb{R}}$. Let $T$ be the holomorphic tangent bundle to $M$. Then the tangent bundle to $M_{R}$ is the realization of $T$ and

$$
p(M)=p\left(T_{\mathbf{R}}\right)=c\left(T_{\mathbf{R}} \otimes \mathbb{C}\right)=c(T \oplus \vec{T})=c(T) c(\vec{T})
$$

So if the total Chern class of the complex manifold $M$ is $c(M)=\Pi\left(1+x_{i}\right)$, then the Pontrjagin class is $p(M)=\Pi\left(1-x_{i}^{2}\right)$.

Remark 22.8.1. If we had followed the usual sign convention for the Pontrjagin classes (see Remark 22.6), the Pontrjagin class of a complex manifold would be $p(M)=\Pi\left(1+x_{i}^{2}\right)$, where the $x_{i}$ 's are defined as above. To have only positive terms in this formula is one of the reasons for the sign in $(-1)^{i} c_{2 i}(E \otimes C)$ in the usual definition of the Pontrjagin class.

Remark 22.9. Let $M$ be a compact oriented manifold of dimension $4 n$. By Poincare duality the wedge product $\wedge: H^{2 n}(M) \otimes H^{2 n}(M) \rightarrow \mathbb{R}$ is a nondegenerate symmetric bilinear form and hence has a signature; this is called the signature of $M$. Recall that the signature of a symmetric matrix is the number of positive eigenvalues minus the number of negative eigenvalues. Hirzebruch proved that the signature is expressible in terms of the Pontrjagin classes.
Hirzebruch signature formula:

$$
\text { signature of } \left.M=\int_{M} L_{1} p_{1}(M), \ldots, p_{4 n}(M)\right)
$$

where $L$ is the polynomial defined in Example 21.11. For a proof of the signature formula, see Milnor and Stasheff [1, p. 224].

Application to the Embedding of a Manifold in a Euclidean Space

Using the Pontrjagin class one can sometimes decide if a conjectured embedding is possible. We illustrate this with the following example.

Example 22.10. Decide if $C P^{4}$ can be differentiably embedded in $\mathbf{R}^{9}$.
By (22.8) and (21.13) the Pontrjagin class of $C P^{4}$ is

$$
p\left(\mathbb{C} P^{4}\right)=c\left(T_{\mathbf{C P}}\right) c\left(\bar{T}_{\mathbf{C P}}\right)=(1+x)^{5}(1-x)^{5}=\left(1-x^{2}\right)^{5} .
$$

If $\mathbb{C} P^{4}$ can be differentiably embedded in $\mathbf{R}^{9}$, then there is an exact sequence

$$
\left.0 \rightarrow\left(T_{C P 4}\right)_{\mathbf{R}} \rightarrow T_{R 9}\right|_{C P 4} \rightarrow N \rightarrow 0,
$$

where $\left(T_{\mathbf{C P 4}}\right)_{\mathbf{R}}$ is the realization of the holomorphic tangent bundle $T_{\mathbf{C P A}}$ and $N$ is the normal bundle of $\mathbb{C} P^{4}$ in $\mathbb{R}^{9}$. By the Whitney product formula

$$
\begin{equation*}
p\left(\left.T_{\mathbf{R}^{9}}\right|_{C^{4} \boldsymbol{q}}\right)=p\left(\left(T_{\mathbf{C P}^{4}}\right)_{\mathbb{R}}\right) p(N) . \tag{22.11}
\end{equation*}
$$

Since the restriction $\left.T_{\mathbf{R}}\right|_{C^{4} 4}$ is the pullback of $T_{R^{9}}$ to $\mathbb{C} P^{4}$ under the embedding $i: \mathbb{C} P^{4} \rightarrow \mathbb{R}^{9}$, by the functoriality of the Pontrjagin class

$$
p\left(T_{R^{9}} \mid c P^{4}\right)=i^{*} p\left(T_{R^{9}}\right)=1 .
$$

Therefore, by (22.11)

$$
\begin{equation*}
p(N)=\frac{1}{p\left(\left(T_{C P 4}\right)_{q}\right)}=\frac{1}{\left(1-x^{2}\right)^{5}}=1+5 x^{2}+15 x^{4} \tag{22.12}
\end{equation*}
$$

Since $N$ is a real line bundle, the top component of $p(N)$ should be in $H^{2}\left(\mathbb{C} P^{4}\right)$. This contradicts the fact that $5 x^{2}$ and $15 x^{4}$ are nonzero classes in $H^{4}\left(\mathbb{C} P^{4}\right)$ and $H^{8}\left(\mathbb{C} P^{4}\right)$. Thus $\mathbb{C} P^{4}$ cannot be embedded in $\mathbf{R}^{9}$.

From (22.12), if $\mathbb{C} P^{4}$ can be embedded in $\mathbf{R}^{n}$, then the normal bundle has rank at least 4, since the top-degree term of the Pontrjagin class of a rank $k$ real bundle is in dimension $2 k$. It follows that $C P^{4}$ cannot be embedded in a Euclidean space of dimension 11 or less.

## §23 The Search for the Universal Bundle

Let $f: M \rightarrow N$ be a complex map between two manifolds and $E$ a complex bundle over $N$. The pullback $f^{-1} E$ is a bundle over $M$. If the Chern classes of $E$ vanish, by the naturality property (20.10.1), sa do those of $f^{-1} E$. Taking the Chern classes to be a measure of the twisting of a bundle, we may assert that pulling back "dilutes" a bundle, i.e., makes it less twisted. One extreme example is when $f$ is constant; in this case $f^{-1} E$ is trivial. Another example is the flag construction of Section 21; pulling $E$ back to the split manifold $F(E)$ splits $E$ into a direct sum of line bundles. One may wonder if there exists a bundle which is so twisted that every bundle is a pullback of this universal bundle. Such a bundle indeed exists, at least for manifolds of finite type; it is the universal quotient bundle on the Grassmannian $G_{k}\left(C^{n}\right)$ for $n$ sufficiently large. We will prove this result and conclude from it that every natural transformation from the complex vector
bundles to the cohomblogy classes is expressible in terms of the Chern classes, all for manifolds of finite type. We also indicate how the theorems generalize to an arbitrary manifold.

## The Grassmannianf

Let $V$ be a complex vector space of dimension $n$. The complex Grassmannian $G_{k}(V)$ is the set of all subspaces of complex codimension $k$ in $V$. We sometimes call such a subspace an ( $n-k$ )-plane in $V$. Given a Hermitian metric on $V$, the unitary group $U(n)$ is the group of all metric-preserving endomorphisms of $V$. Clearly $U(n)$ acts transitively on the collection of all ( $n-k$ )-planes in $V$. Since a unitary matrix which sends an $(n-k)$-plane to itself must also fix the complementary orthogonal $k$-plane, the stabilizer of an $(n-k)$-plane in $V$ is $U(n-k) \times U(k)$. Thus the Grassmannian can be represented as a homogeneous space

$$
G_{k}(V)=\frac{U(n)}{U(k) \times U(n-k)} .
$$

As the coset space of a Lie group by a closed subgroup, $G_{k}(V)$ is a differentiable manifold (Warner [1, p. 120]). Note that $G_{n-1}(V)$ is the projective space $P(V)$.

Just as in the case of the projective space, over the Grassmannian $G_{k}(V)$ there are three tautological bundles: the universal subbundle $S$, whose fiber at each point $\Lambda$ of $G_{k}(V)$ is the $(n-k)$-plane $\Lambda$ itself; the product bundle $\hat{V}=G_{k}(V) \times V$; and the universal quotient bundle $Q$ defined by

$$
0 \rightarrow S \rightarrow \hat{V} \rightarrow Q \rightarrow 0 .
$$

This exact sequence is called the tautological sequence on $G_{k}(V)$. Over $G_{k}(V)$ the universal subbundle $S$ has rank $n-k$ and the universal quotient bundle has rank $k$.

Similarly, if $V$ is a real vector space, one can define the real Grassmannian $G_{k}(V)$ of codimension $k$ real subspaces of $V$, and the analogous real universal bundles. The real Grassmannian can also be represented as a homogeneous space

$$
G_{k}\left(\mathbb{R}^{n}\right)=\frac{O(n)}{O(k) \times O(n-k)} .
$$

Proposition 23.1. The cohomology of the complex Grassmannian $G_{k}(V)$ has Poincaré polynomial

$$
P_{A}\left(G_{k}(V)\right)=\frac{\left(1-t^{2}\right) \cdots\left(1-t^{2 n}\right)}{\left(1-t^{2}\right) \cdots\left(1-t^{2 k}\right)\left(1-t^{2}\right) \cdots\left(1-t^{2(n-k)}\right)}
$$

Proof. The flag manifold $F(V)$ may be obtained from the Grassmannian $G_{k}(V)$ by a series of flag constructions as follows. Let $\hat{Q}$ be the pullback of $Q$ to the flag bundle $F(S)$.

A point of $F(S)$ is a pair $\left(\Lambda, L_{1} \subset \cdots \subset \Lambda\right)$ consisting of an $(n-k)$-plane $\Lambda$ in $V$ together with a flag in $\Lambda$. Therefore a point in $F(\hat{Q})$ consists of a point in $F(S),\left(\Lambda, L_{1} \subset \cdots \subset \Lambda\right)$, together with a flag in $V / \Lambda$, i.e., a point in $F(Q)$ is given by $\left(\Lambda, L_{1} \subset \cdots \subset L_{n-k-1} \subset \Lambda \subset L_{n-k+1} \subset \cdots \subset V\right)$. So $F(\hat{Q})$ is the flag manifold $F(V)$, and $F(V)$ is obtained from the Grassmannian $G_{k}(V)$ by two flag constructions. By (21.18); the Poincaré polynomials of $F(V)$ and $G_{k}(V)$ satisfy the relation

$$
P_{\lambda}(F(V))=P_{\lambda}\left(G_{k}(V)\right) \frac{\left(1-t^{2}\right) \cdots\left(1-t^{2(n-k)}\right)\left(1-t^{2}\right) \cdots\left(1-t^{2 h}\right)}{\left(1-t^{2}\right) \cdots\left(1-t^{2}\right)\left(1-t^{2}\right) \cdots\left(1-t^{2}\right)} .
$$

From (21.17) it follows that

$$
P_{त}\left(G_{k}(V)\right)=\frac{\left(1-t^{2}\right) \cdots\left(1-t^{2 n}\right)}{\left(1-t^{2}\right) \cdots\left(1-t^{2(n-k)}\right)\left(1-t^{2}\right) \cdots\left(1-t^{2 k}\right)} .
$$

As for the ring structure of the cohomology of the Grassmannian $G_{k}\left(V_{h}\right.$ we have the following.

Proposition 23.2. Let $V$ be a complex vector space of dimension $n$.
(a) As a ring

$$
H^{*}\left(G_{k}(V)\right)=\frac{R\left[c_{1}(S), \ldots, c_{n-k}(S), c_{1}(Q), \ldots, c_{k}(Q)\right]}{(c(S) c(Q)=1)}
$$

(b) The Chern classes $c_{1}(Q), \ldots, c_{k}(Q)$ of the quotient bundle generate the cohomology ring $H^{*}\left(G_{k}(V)\right)$.
(c) For a fixed $k$ and a fixed $i$ there are no polynomial relations of degree $i$ among $c_{1}(Q), \ldots, c_{k}(Q)$ if the dimension of $V$ is large enough.
Proof. In the proof of Proposition 23.1, we saw that the flag manifold $F(V)$ is obtained from the Grassmannian by two flag constructions

By (21.18) the cohomology ring of the flag manifold is

$$
H^{*}(F(V))=\frac{H^{*}\left(G_{k}(V)\right)\left[x_{1}, \ldots, x_{n-k}, y_{1}, \ldots, y_{k}\right]}{\left(\prod\left(1+x_{i}\right)=c(S), \prod\left(1+y_{j}\right)=c(Q)\right)}
$$

On the other hand, we've computed the cohomology of $F(V)$ in (21.17) to be
(*) $\quad H^{*}(F(V))=\mathbb{R}\left[x_{1}, \ldots, x_{n-k}, y_{1}, \ldots, y_{k}\right] /\left(\prod\left(1+x_{i}\right) \prod\left(1+y_{j}\right)=1\right)$.
Thus in $H^{*}\left(G_{k}(V)\right)$ the Chern classes of $S$ and $Q$ can satisfy no relation other than $c(S) c(Q)=1$, for any relation among them would appear as a relation among the $x_{i}$ 's and $y_{j}$ 's in (*). It follows that there is an injection of algebras

$$
\begin{equation*}
\frac{\mathbb{R}[c(S), c(Q)]}{(c(S) c(Q)=1)} \hookrightarrow H^{*}\left(G_{k}(V)\right) . \tag{23.2.1}
\end{equation*}
$$

From the digression following this proof, the Poincare series of $\mathbb{R}\left[c_{1}(S), \ldots, c_{n-k}(S), c_{1}(Q), \ldots, c_{k}(Q)\right] /(c(S) c(Q)=1)$ is

$$
P_{t}\left(\frac{\mathbb{R}[c(S), c(Q)]}{(c(S) c(Q)=1)}\right)=\frac{\left(1-t^{2}\right) \cdots\left(1-t^{2 n}\right)}{\left(1-t^{2}\right) \cdots\left(1-t^{2(n-k)}\right)\left(1-t^{2}\right) \cdots\left(1-t^{2 k}\right)} .
$$

But this is also the Poincare series of $H^{*}\left(G_{k}(V)\right)$. Thus the injection (23.2.1) is an isomorphism. This proves (a).

Writing $c(S)=1 / c(Q)$, we see from the description of the ring structure in (a) that $c_{1}(Q), \ldots, c_{k}(Q)$ generate the cohomology ring of $G_{k}(V)$.

The equation $c(S)=1 / c(Q)$ not only allows one to eliminate $c_{1}(S), \ldots$, $c_{n-k}(S)$ in terms of $c_{1}(Q), \ldots, c_{k}(Q)$, but also gives polynomial relations of degrees $2(n-k+1), \ldots, 2 n$ among $c_{1}(Q), \ldots, c_{k}(Q)$. Thus for a given degree $i$, if the dimension $n$ of the vector space $V$ is so large that $2(n-k+1)>i$, then there are no polynomial relations of degree $i$ among the Chern classes of $Q$.

## Digression on the Poincaré Series of a Graded Algebra

Let $k$ be a field and $A=\bigoplus_{i=1}^{\infty} A_{i}$ a graded algebra over $k$. The Poincaré, series of $A$ is defined to be

$$
P_{\ell}(A)=\sum_{\ell=0}^{\infty}\left(\operatorname{dim}_{k} A_{i}\right) t^{l} .
$$

If $A$ is a graded $\mathbb{Z}$-module, its Poincare series is defined to be that of the $\mathbb{Q}$-algebra $A \otimes_{z} \mathbb{Q}$.

Example. Let $A$ be the polynomial ring $\mathbb{R}[x]$, where $x$ is an element of degree $n$. Then

$$
P_{n}(A)=1+t^{n}+t^{2 n}+\cdots=\frac{1}{1-t^{n}} .
$$

Example. Let $A$ and $B$ be two graded algebras. Suppose a basis for $A$ as a vector space is $\left\{x_{i}\right\}_{i \in I}$ and a basis for $B$ is $\left\{y_{j}\right\}_{j \in J}$. Then a vector space basis for $A \otimes B$ is $\left\{x_{l} \otimes y_{j}\right\}_{i \in I, j \in J}$. Therefore

$$
P_{t}(A \otimes B)=P_{d}(A) P_{d}(B)
$$

Example. Let $A=\mathbb{R}[x, y]$, with $\operatorname{deg} x=m$ and $\operatorname{deg} y=n$. Then since $\mathbb{R}[x, y]=\mathbb{R}[x] \otimes \mathbb{R}[y]$,

$$
P_{t}(A)=P_{d}(\mathbb{R}[x]) P_{t}(\mathbb{R}[y])=\frac{1}{1-t^{m}} \cdot \frac{1}{1-t^{n}}
$$

We next investigate the effect of a relation on the Poincare series of a graded algebra.

Proposition 23.3. Let $A=\bigoplus_{i=0}^{\infty} A_{i}$ be a graded algebra over a field $k$, and $x a$ homogeneous element of degree $n$ in $A$. If $x$ is not a zero-divisor, then

$$
P_{r}(A / x A)=P_{r}(A)\left(1-t^{n}\right) .
$$

Proof. Because $x$ is not a zero-divisor, multiplication by $x$ is an injection. Hence for each integer $i$ there is an exact sequence of vector spaces

$$
0 \rightarrow A_{i} \xrightarrow{x} A_{i+n} \rightarrow(A / x A)_{i+n} \rightarrow 0
$$

By the additivity of the dimension,

$$
\operatorname{dim} A_{i+n}=\operatorname{dim} A_{i}+\operatorname{dim}(A / x A)_{i+n}
$$

Summing over all $\boldsymbol{i}$,

$$
\sum_{i=-n}^{\infty}\left(\operatorname{dim} A_{i+n}\right) t^{i+n}=\sum_{i=-n}^{\infty}\left(\operatorname{dim} A_{i}\right) t^{i+n}+\sum_{i=-n}^{\infty} \operatorname{dim}(A / x A)_{i+n} t^{i+n}
$$

where we set $A_{i}=\{0\}$ if $i$ is negative. Hence

$$
P_{N}(A)=P_{N}(A) t^{n}+P_{N}(A / x A)
$$

Example. If $x, y$, and $z$ are elements of degree 1, then the Poincare series of $A=R[x, y, z] /\left(x^{3} y+y^{2} z^{2}+x y^{2} z\right)$ is

$$
\begin{aligned}
P_{V}(A) & =P_{V}(R[x, y, z])\left(1-t^{4}\right) \\
& =\left(1-t^{4}\right) /\left(1-t^{3}\right)
\end{aligned}
$$

To generalize Proposition 23.3, we will need the notion of a regular sequence.

Definition. Let $A$ be a ring. A sequence of elements $a_{1}, \ldots, a_{r}$ in $A$ is a regular sequence if $a_{1}$ is not a zero-divisor in $A$ and for each $i \geq 2$, the image of $a_{i}$ in $A /\left(a_{1}, \ldots, a_{i-1}\right)$ is not a zero-divisor.

Proposition 23.4. Let $A$ be a graded algebra over a field $k$ and $a_{1}, \ldots, a_{r} a$ regular sequence of homogeneous elements of degrees $n_{1}, \ldots, n_{r}$. Then

$$
P_{N}\left(A /\left(a_{i}, \ldots, a_{r}\right)\right)=P_{R}(A)\left(1-t^{n_{1}}\right) \cdots\left(1-t^{\star}\right) .
$$

Proof. This is an immediate consequence of Proposition 23.3 and induction on $r$.

Let $I$ be the ideal in $\mathbb{R}\left[x_{1}, \ldots, x_{j}, y_{1}, \ldots, y_{k}\right]$ generated by the homogeneous terms of $\left(1+x_{1}+\cdots+x_{j}\right)\left(1+y_{1}+\cdots+y_{k}\right)-1$. We will now compute the Poincare series of $\mathbb{R}\left[x_{1}, \ldots, x_{j}, y_{1}, \ldots, y_{k}\right] / I$.

Lemma 23.5. Let A be a graded algebra over a field $k$. If $a_{1}, \ldots, a_{1}$ is a regular sequence of homogeneous elements of positive degrees in $A$, so is any permutation of $a_{1}, \ldots, a_{r}$.

Proof. Since any permutation is a product of transpositions of adjacent elements, it suffices to show that $a_{1}, \ldots, a_{i-1}, a_{i+1}, a_{i}, \ldots, a_{r}$ is a regular sequence. For this it is enough to show that in the ring $A /\left(a_{1}, \ldots, a_{t-1}\right)$, the images of $a_{i+1}, a_{i}$ form a regular sequence. In this way the lemma is reduced to the case of two elements: if $a, b$ is a regular sequence of elements of positive degrees in the graded algebra $A$, so is $b, a$.

If $x$ is an element of $A$, we write $\bar{x}$ for the image of $x$ in whatever quotient ring of $A$ being discussed. Assume that $a, b$ is a regular sequence in A.
(1) Suppose $b x=0$ in $A$. Then $\bar{b} \bar{x}=0$ in $A /(a)$. Since $\bar{b}$ is not a zero-divisor in $A /(a), x=a x_{1}$ for some $x_{1}$ in $A$. Therefore, $a b x_{1}=0$ in $A$. Since $a$ is not a zero divisor, $b x_{1}=0$. Repeating the argument, we get $x_{1}=a x_{2}$, $x_{2}=a x_{3}$, and so on. Thus $x=a x_{1}=a^{2} x_{2}=a^{3} x_{3}=\ldots$, showing that $x$ is divisible by all the powers of $a$. Since $a$ has positive degree, this is possible only if $x=0$. Therefore $b$ is not a zero-divisor in $A$.
(2) Next we show that $\bar{a}$ is not a zero-divisor in $A /(b)$. Suppose $\bar{a} \bar{x}=0$ in $A /(b)$. Then $a x=b y$ for some $y$ in $A$. It follows that $b \bar{y}=0$ in $A /(a)$. Since $\bar{b}$ is not a zero-divisor in $A /(a), y=a z$ for some $z$. Therefore, $a x=a b z$. Since $a$ is not a zero-divisor in $A, x=b z$; hence, $\bar{x}=0$ in $A /(b)$.

Lemms 23.6. If $a_{1}, \ldots, a_{r}, b$ and $a_{1}, \ldots, a_{r}, c$ are regular sequences in a ring $A$, then so is $a_{1}, \ldots, a_{r}, b c$.

Proof. It suffices to check that $b c$ is not a zero-divisor in $A /\left(a_{1}, \ldots, a_{r}\right)$. This is clear since by hypothesis neither $b$ nor $c$ is a zero-divisor in $A /\left(a_{1}, \ldots, a_{r}\right)$.

Proposition 23.7. The homogeneous terms of

$$
\left(1+x_{1}+\cdots+x_{j}\right)\left(1+y_{1}+\cdots+y_{k}\right)-1
$$

form a reaular sequence in $A=\mathbb{R}\left[x_{1}, \ldots, x_{j}, y_{1}, \ldots, y_{k}\right]$.
Proof. The proof proceeds by induction on $j$ and $k$. Suppose $j=1$ and $k=1$. Then $\mathbb{R}\left[x_{2}, y_{1}\right] /\left(x_{1}+y_{1}\right)=\mathbb{R}\left[x_{1}\right]$ and the image of $x_{1} y_{1}$ in $\mathbb{R}\left[x_{1}\right.$, $\left.y_{1}\right] /\left(x_{1}+y_{1}\right)$ is $-x_{1}^{2}$, which is not a zero divisor. So $x_{1}+y_{1}, x_{1} y_{1}$ is a regular sequence in $\mathbb{R}\left[x_{1}, y_{1}\right]$. For a general $j$ and $k$, let $f_{1}$ be the homogeneous term of degree $i$ in $\left(1+x_{1}+\cdots+x_{j}\right)\left(1+y_{1}+\cdots+y_{k}\right)-1$. We first show that $f_{1}, \ldots, f_{j+k-1}, x_{j}$ and $f_{1}, \ldots, f_{j+k-1}, y_{k}$ are regular sequences. By Lemma $23.5, f_{1}, \ldots, f_{j+k-1}, x_{j}$ is a regular sequence if and only if $x_{j}, f_{1}, \ldots$, $f_{f+k-1}$ is. Let $f_{i}$ be the image of $f_{i}$ in $A /\left(x_{j}\right)$. Since $x_{j}$ is not a zero-divisor in $A$, it suffices to show that $\bar{f}_{1}, \ldots, \bar{f}_{j+k-1}$ is a regular sequence in $A /\left(x_{j}\right)$. This is true by the induction hypothesis, since

$$
A /\left(x_{j}\right)=\mathbf{R}\left[x_{1}, \ldots, x_{j-1}, y_{1}, \ldots, y_{k}\right]
$$

and

$$
1+\bar{f}_{1}+\cdots+\bar{f}_{j+k-1}=\left(1+x_{1}+\cdots+x_{j-1}\right)\left(1+y_{1}+\cdots+y_{k}\right) .
$$

Therefore, $f_{1}, \ldots, f_{j+k-1}, x_{j}$ is a regular sequence in $A$. Similarly, $f_{1}, \ldots$, $f_{j+k-1}, y_{k}$ is also a regular sequence in $A$. By Lemma 23.6 , so is $f_{1}, \ldots$, $f_{j+k-1}, x_{j} y_{k}$.

By Propositions 23.4 and 23.7, if $I$ is the ideal in

$$
A=R\left[x_{1}, \ldots, x_{n-k}, y_{1}, \ldots, y_{k}\right]
$$

generated by the homogeneous terms of

$$
\left(1+x_{1}+\cdots+x_{n-k}\right)\left(1+y_{1}+\cdots+y_{k}\right)-1,
$$

where deg $x_{i}=2 i$ and $\operatorname{deg} y_{i}=2 i$, then the Poincaré series of $A / I$ is

$$
P_{n}(A / I)=\frac{\left(1-t^{2}\right) \cdots\left(1-t^{2 \eta}\right)}{\left(1-t^{2}\right) \cdots\left(1-t^{2(t-k)}\right)\left(1-t^{2}\right) \cdots\left(1-t^{2 h}\right)}
$$

## The Classification of Vector Bundles

We now show that the vector bundles over a manifold $M$ may be classified up to isomorphism by the homotopy classes of maps from $M$ into a Grassmannian. We will first discuss this in the complex case and then extend it by analogy to the real case.

Lemma 23.8. Let $E$ be a rank $k$ complex vector bundle over a differentiable manifold $M$ of finite type. There exist on $M$ finitely many smooth sections of $E$ which span the fiber at every point.

Proof. Let $\left\{U_{i}\right\}_{i \in I}$ be a finite good cover for $M$. Since $U_{i}$ is contractible, $\left.E\right|_{U_{i}}$ is trivial and so we can find $k$ sections $s_{i, 1}, \ldots, s_{i, k}$ over $U_{i}$ which form a basis of the fiber above any point in $U_{i}$. By the Shrinking Lemma (see (21.4) and (21.5)), there is an open cover $\left\{V_{i}\right\}_{i \in I}$ with $\bar{V}_{i} \subset U_{i}$ and smooth functions $f_{i}$ such that $f_{i}$ is identically 1 on $V_{i}$ and identically 0 outside $U_{i}$. Then $\left\{f_{i} s_{i, 1}, \ldots, f_{i} s_{i, k}\right\}_{i \in I}$ are global sections of $E$ which span the fiber at every point.

Proposition 23.9. Let $E$ be a rank $\dot{k}$ complex vector bundle over a differentiable manifold $M$ of finite type. Suppose there are $n$ global sections of $E$ which span the fiber at every point. Then there is a map from $M$ to some Grassmannian $G_{k}\left(\mathbb{C}^{n}\right)$ such that $E$ is the pullback under $f$ of the universal quotient bundle $Q$; that is, $E=f^{-1} Q$.

Proof. Let $s_{1}, \ldots, s_{n}$ be $n$ spanning sections of $E$ and let $V$ be the complex vector space with basis $s_{1}, \ldots, s_{n}$. Since $s_{1}, \ldots, s_{n}$ are spanning sections, for each point $p$ in $M$ the evaluation map

$$
\mathrm{ev}_{p}: V \rightarrow E_{p} \rightarrow 0
$$

is surjective. Hence ker $\mathrm{ev}_{p}$ is a codimension $k$ subspace of $V$, and the fiber of the universal quotient bundle $Q$ at the point $\mathrm{ker} \mathrm{ev}_{p}$ of the Grassmannian $G_{k}(V)$ is $V / \operatorname{ker}^{\mathrm{ev}} \mathrm{v}_{p}=E_{p}$. If the map $f: M \rightarrow G_{k}(V)$ is defined by

$$
f: p \mapsto \text { ker } e v_{p}
$$

then the quotient bundle $Q$ pulls back to $E$. We can identify $V$ with $\mathbb{C}^{n}$, and $G_{k}(V)$ with $G_{k}\left(\mathbb{C}^{n}\right)$.

This map $f: M \rightarrow G_{k}\left(\mathbb{C}^{n}\right)$ is called a classifying map for the bundle $E$.
In the proposition above, if $\left\{s_{1}^{\prime}, \ldots, s_{n}^{\prime}\right\}$ is another choice of global sections which span the fiber at every point, and $V^{\prime}$ the vector space with basis $s_{1}^{\prime}, \ldots, s_{n}^{\prime}$, then there is a natural isomorphism of $V$ with $V^{\prime}$, and of $G_{k}(V)$ with $G_{k}\left(V^{\prime}\right)$. Therefore the classifying map $f: M \rightarrow G_{k}\left(C^{n}\right)$ is well-defined up to the identification of $V$ with $\mathbb{C}^{a}$, independent of the choice of the $n$ spanning sections. More precisely, any two such maps $f$ and $f^{\prime}$ from $M$ to $G_{k}\left(C^{n}\right)$ differ by the action of an element $B$ of $G L(n, C)$ on $G_{k}\left(\mathbb{C}^{\prime \prime}\right)$; that is,

$$
f^{\prime}=B \circ f, \quad \text { where } \quad B: G_{k}\left(\mathbb{C}^{\prime \prime}\right) \rightarrow G_{k}\left(\mathbb{C}^{\prime \prime}\right)
$$

Since $G L(n, \mathbb{C})$ is connected, there is a path $\gamma(t)$ joining the identity element $I$ and $B$ in $G L(n, \mathbb{C})$. Then $f_{t}=\gamma(t) \circ f$ is a homotopy between $f$ and $f^{\prime}$. Therefore we may refine Proposition 23.9 to include the following statement.
(23.9.1) The homotopy class of the classifying map $f: M \rightarrow G_{k}\left(C^{n}\right)$ of the vector bundle $E$ is uniquely determined by $E$.

In fact, if $g: E \rightarrow E^{\prime}$ is an isomorphism of vector bundles over $M$, then $g$ gives a one-to-one correspondence between the sections of $E$ and the sections of $E^{\prime}$. So by the same reasoning as in (23.9.1), we see that $E$ and $E^{\prime}$ determine homotopic classifying maps $f$ and $f^{\prime}$ from $M$ to the Grassmannian $G_{k}\left(\mathbb{C}^{n}\right)$. Writing $\operatorname{Vect}_{k}(M ; \mathbb{C})$ for the isomorphism classes of the rank $k$ complex vector bundles over $M$ and $[X, Y]$ for the set of all homotopy classes of maps from $X$ to $Y$, we have the following.
(23.9.2) For $n$ sufficiently large, there is a well-defined map

$$
\beta: \operatorname{Vect}_{k}(M ; \mathbb{C}) \rightarrow\left[M, G_{k}\left(C^{n}\right)\right]
$$

given by the classifying map of a vector bundle.
Remark 23.9.3. Frem the proof of Lemma 23.8 , if $M$ has a good cover with $r$ open sets, then every rank $k$ bundle over $M$ has a set of $r k$ spanning sections. Thus in (23.9) given the manifold $M$ of finite type and the integer $k$, if $n$ is an integer $\geq r k$, then the Grassmannian $G_{k}\left(C^{n}\right)$ classifies, all vector bundles of rank $k$ over $M$.

Theorem 23.10. Let $M$ be a manifold having a good cover consisting of $r$ open. sets and let $k$ be a positive integer, For every integer $n \geq k r$, there is a one-to-one correspondence

$$
\operatorname{Vect}_{k}(M ; \mathbb{C}) \simeq\left[M, G_{k}\left(\mathbb{C}^{N}\right)\right]
$$

between the isomorphism classes of rank $k$ complex vector bundles over $M$ and the homotopy classes of maps from $M$ into the complex Grassmannian. $G_{k}\left(\mathrm{C}^{n}\right)$.

Proof. By the homotopy property of vector bundles (Theorem 6.8), there is a map

$$
\alpha:\left[M, G_{k}\left(\mathbb{C}^{n}\right)\right] \rightarrow \operatorname{Vect}_{k}(M ; \mathbb{C})
$$

given by the pullback of the universal quotient bundle over $G_{k}\left(\mathbb{C}^{n}\right)$ :

$$
f \mapsto f^{-1} c
$$

By (23.9), (23.9.2), and (23.9.3), for any integer $n \geq r k$, the map

$$
\beta: \operatorname{Vect}_{k}(M ; \mathbb{C}) \rightarrow\left[M, G_{k}\left(\mathbb{C}^{\prime}\right)\right]
$$

given by the homotopy class of the classifying map of a vector bundle, is inverse to $\alpha$.

As a corollary of the existence of the universal bundle (23.9), we now show that in a precise sense the Chern classes are the only cohopological invariants of a smooth complex vector bundle.

Proposition 23.11. Every natural transformation from the isomorphism classes of complex vector bundles over a manifold of finite type to the de Rham cohomology can be given as a polynomial in the Chern classes.

Proof. Let $T$ be a natural transformation from the functor Vect $_{k}(; \mathbb{C})$ to the functor $H^{*}()$ in the category of manifolds of finite type. By Proposition 23.9 and the naturality of $T$, if $E$ is any rank $k$ complex vector bundle over $M$ and $f: M \rightarrow G_{k}\left(C^{\prime \prime}\right)$ a classifying map for $E$, then

$$
T(E)=T\left(f^{-1} Q\right)=f^{*} T(Q) .
$$

Because the cohomology of the Grassmannian $G_{k}\left(C^{\prime \prime}\right)$ is generated by the Chern classes of $Q$ (Prop. 23.2(b)), $T(Q)$ can be written as

$$
T(Q)=P_{T}\left(c_{1}(Q), \ldots, c_{k}(Q)\right)
$$

for some polynomial $P_{T}$ depending on $T$. Therefore

$$
T(E)=f^{*} T(Q)=P_{T}\left(f^{*} c_{1}(Q), \ldots, f^{*} c_{k}(Q)\right)=P_{T}\left(c_{1}(E), \ldots, c_{k}(E)\right)
$$

Of course there is an analogue of Theorem 23.10 for real vector bundles. Recall that we write $\operatorname{Vect}_{k}(M)$ for the isomorphism classes of the rank $k$ real vector bundles over M.

Theorem 23.12. Let $M$ be a manifold having a good cover consisting of $r$ open sets and $k$ a positive integer. For every integer $n \geq r k$, there is a one-to-one correspondence

$$
\operatorname{Vect}_{k}(M) \simeq\left[M, G_{k}\left(R^{\prime \prime}\right)\right]
$$

The proof is completely analogous to that of Theorem 23.10.
We now classify the vector bundles over spheres and relate them to the homotopy groups of the orthogonal and unitary groups.

Exercise 23.13. (a) Use Exercise 17.24 and the homotopy exact sequence of the fibration

to show that

$$
\pi_{\&}\left(G_{k}\left(\mathbb{R}^{n}\right)\right)=\pi_{q-1}(O(k)) \text { if } n \geq k+q+2
$$

(b) Similarly show that

$$
\pi_{d}\left(G_{k}\left(\mathbb{C}^{n}\right)\right)=\pi_{q-1}(U(k)) \text { if } n \geq(2 k+q+1) / 2
$$

Casobining these formulas with Proposition 17.6.1 concerning the relation of free versus base-point perserving homotopies we find that for $n$
sufficiently large,

$$
\begin{aligned}
\operatorname{Vect}_{k}\left(S^{q}\right) & =\left[S^{q}, G_{k}\left(\mathbb{R}^{q}\right)\right] \\
& =\pi_{q}\left(G_{k}\left(\mathbb{R}^{q}\right)\right) / \pi_{1}\left(G_{k}\left(\mathbf{R}^{\prime}\right)\right) \\
& =\pi_{q-1}(O(k)) / \pi_{0}(O(k))
\end{aligned}
$$

Exactly the same computation works for the complex vector bundles over $S^{\ell}$. We summarize the results in the following.

Proposition 23.14. The isomorphism classes of the differentiable rank $k$ real vector bundles over the sphere $S^{4}$ are given by

$$
\operatorname{Vect}_{k}\left(S^{q}\right) \simeq \pi_{q-1}(O(k)) / \mathbf{Z}_{2} ;
$$

the isomorphism classes of the complex vector bundles are given by

$$
\operatorname{Vect}_{k}\left(S^{\varphi} ; \mathrm{C}\right) \simeq \pi_{e-1}(U(k))
$$

Remark 23.14.1 If $G$ is a Lie group and $a \in G$, then conjugation by $a$ defines an automorphism $h_{a}$ of $G$ :

$$
h_{a}(g)=a g a^{-1}
$$

Let $m$ be any integer. The map $h_{a}$ induces a map of homotopy groups:

$$
\left(h_{a}\right)_{*}: \pi_{m}(G) \rightarrow \pi_{m}(G)
$$

If two elements $a$ and $b$ in $G$ can be joined by a path $\gamma(t)$ in $G$, then $h_{a}$ is homotopic to $h_{b}$ via the homotopy $h_{\gamma(t)}$. Consequently $\left(h_{a}\right)_{z}=\left(h_{b}\right)_{*}$. In this way conjugation induces an action of $\pi_{0}(G)$ on $\pi_{m}(G)$, called the adjoint action.

We know from (17.6) that for any space $X$ with base point $x$, conjügation on the loop space $\Omega_{x} X$ induces an action of $\pi_{1}(X)$ on $\pi_{8}(X)$. With a little more classifying space theory, it can be shown that the action of $\pi_{0}(O(k))$ on $\pi_{q-1}(O(k))$ corresponding to the action of $\pi_{1}\left(G_{k}\left(\mathbb{R}^{n}\right)\right)$ on $\pi_{q}\left(G_{k}\left(\mathbb{R}^{n}\right)\right)$ under the identification of $\pi_{\mathbf{q}-1}(O(k))$ with $\pi_{\&}\left(G_{k}\left(R^{\prime \prime}\right)\right)$ is precisely the adjoint action.

Remark 23.14.2. It is in fact possible to explain the correspondence (23.14) directly. Let $E$ be a rank $k$ vector bundle over $S^{4}$ with structure group $O(k)$, and let $U_{0}$ and $U_{1}$ be small open neighborhoods of the upper and lower hemispheres. Because $U_{0}$ and $U_{1}$ are contractible, $E$ is trivial over them. Hence $E$ is completely determined by the transition function

$$
g_{01}: U_{0} \cap U_{1} \rightarrow O(k)
$$

$g_{01}$ is called a clutching function for E. Then Proposition 23.14 may be interpreted as a correspondence between the isomorphism classes of vector bundles over a sphere and the free homotopy classes of the clutching functions.

Exercise 23.15. Compute $\operatorname{Vect}_{k}\left(S^{1}\right), \operatorname{Vect}_{k}\left(S^{2}\right)$, and $\operatorname{Vect}_{k}\left(S^{3}\right)$.
Example 23.16 (An orientable sphere bundle with zero Euler class but no section). Because $S^{4}$ is simply connected, every vector bundle over $S^{4}$ is orientable (Proposition 11.5). For a line bundle orientability implies triviality. Therefore,

$$
\operatorname{Vect}_{1}\left(S^{4}\right)=0 .
$$

By (23.14),

$$
\begin{aligned}
\operatorname{Vect}_{2}\left(S^{4}\right) & =\pi_{3}(S O(2)) / \mathbb{Z}_{2}=\pi_{3}\left(S^{1}\right) / \mathbb{Z}_{2}=0 \\
\operatorname{Vect}_{3}\left(S^{4}\right) & =\pi_{3}(S O(3)) / \mathbb{Z}_{2}=\pi_{3}\left(\mathbb{R} P^{3}\right) / \mathbb{Z}_{2} \\
& =\pi_{3}\left(S^{3}\right) / \mathbb{Z}_{2}=\mathbb{Z} / \mathbb{Z}_{2}
\end{aligned}
$$

Consequently there is a nontrivial rank 3 vector bundle $E$ over $S^{4}$. The Euler class of $E$ vanishes trivially, since $e(E)$ is in $H^{3}\left(S^{4}\right)=0$. If $E$ has a nonzero global section, it would split into a direct sum $E=L \oplus F$ of a line bundle and a rank 2 bundle. Since $\operatorname{Vect}_{1}\left(S^{4}\right)=\operatorname{Vect}_{2}\left(S^{4}\right)=0$, this would imply that $E$ is trivial, a contradiction. Therefore the unit sphere bundle of $E$ relative to some Riemannian metric is an orientable $S^{2}$-bundle over $S^{4}$ with zero Euler class but no section. This example shows that the converse of Proposition 11.9 is not true.

Remark 23.16.1 Actually $\operatorname{Vect}_{3}\left(S^{4}\right) \simeq \mathbb{Z}$, because the action of $\mathbb{Z}_{2}$ on $\pi_{3}(S O(3))$ is trivial. Indeed, by Remark 23.14 .1 this action is induced by the action of $-1 \in O(3)$ under conjugation on $S O(3)$. But conjugating by -1 clearly gives the identity map.

In general, by the same reasoning, if $k$ is odd, then the action of $\pi_{0}(O(k))$ on $\pi_{q}(O(k))$ is trivial for all $q$.

## The Infinite Grassmannian

We will now say a few words about vector bundles over manifolds not having a finite good cover. For Theorem 23.10 to hold here the analogue of the finite Grassmannian is the infinite Grassmannian. Given a sequence of complex vector spaces

$$
\cdots \subset V_{r} \subset V_{r+1} \subset V_{r+2} \subset \cdots \quad \operatorname{dim}_{c} V_{1}=i
$$

there is a naturally induced sequence of Grassmannians

$$
\cdots \subset G_{k}\left(V_{r}\right) \subset G_{k}\left(V_{r+1}\right) \subset G_{k}\left(V_{r+2}\right) \subset \cdots
$$

The infinite Grassmannian $G_{k}\left(V_{\infty}\right)$ is the telescope constructed from this sequence. Over each $G_{k}\left(V_{r}\right)$ there are the universal quotient bundles $Q_{r}$ and there are maps

$$
\cdots \subset Q_{r} \subset Q_{r+1} \subset Q_{r+2} \subset \cdots .
$$

By the telescoping construction again there is a bundle $Q$ of rank $k$ over $G_{k}\left(V_{\infty}\right)$. A point of $G_{k}\left(V_{\infty}\right)$ is a subspace $\Lambda$ of codimension $k$ in $V$ and the fiber of $Q$ over $\Lambda$ is the $k$-dimensional quotient space $V_{\infty} / \Lambda$.

Unfortunately the infinite Grassmannian is infinite-dimensional and so is not a manifold in our sense of the word. Since to discuss infinitedimensional manifolds would take us too far afield, we will merely indicate how our theorems may be extended. By the countable analogue of the Shrinking Lemma (Ex. 21.4), with the finite cover replaced by a countable locally finite cover, one can show just as in Lemma 23.8 that every vector bundle over an arbitrary manifold $M$ has a collection of countably many spanning sections $s_{1}, s_{2}, \ldots$. If $V_{\infty}$ is the infinite-dimensional vector space with basis $s_{1}, s_{2}, \ldots$, there is again a surjective evaluation map at each point $p$ in $M$ :

$$
\mathrm{ev}_{p}: V_{\infty} \rightarrow E_{p} \rightarrow 0 .
$$

The kernel of $\mathrm{ev}_{p}$ is a codimension $k$ subspace of $V_{\infty}$. So the function $f(p)=\operatorname{ker} \mathrm{ev}_{p}$ sends $M$ into the infinite Grassmannian $G_{k}\left(V_{\infty}\right)$. This map $f$ is a classifying map for the vector bundle $E$ and there is again a one-to-one correspondence

$$
\operatorname{Vect}_{k}(M ; \mathbb{C}) \simeq\left[M, G_{k}\left(\mathbb{C}^{\infty}\right)\right]
$$

All this can be proved in the same way as for manifolds of finite type. From Proposition 23.2, it is reasonable to conjecture that the cohomology ring of the infinite Grassmannian $G_{k}\left(\mathbb{C}^{\infty}\right)$ is the free polynomial algebra

$$
\mathbb{R}\left[c_{1}(Q), \ldots, c_{k}(Q)\right] .
$$

This is indeed the case. (For a proof see Milnor and Stasheff [1, p. 161] or Husemoller [1, Ch. 18, Th. 3.2, p. 269].) Hence Proposition 23.11 extends to a general manifold.
, $k$
Exercise 23.17. Let $V$ be a vector space over $\mathbf{R}$ and $V^{*}=\operatorname{Hom}(V, R)$ its dual.
(a) Show that $P\left(V^{*}\right)$ may be interpreted as the set of all hyperplanes in $V$.
(b) Let $Y \subset P(V) \times P\left(V^{*}\right)$ be defined by

$$
Y=\left\{([v],[H]) \mid H(v)=0, v \in V, H \in V^{*}\right\} .
$$

In other words, $Y$ is the incidence correspondence of pairs (line in $V$, hyperplane in $V$ ) such that the line is contained in the hyperplane. Compute $H^{*}(Y)$.

Concluding Remarks
In the preceding sections the Chern classes of a vector buncile $E$ over $M$ were first defined by studying the relations in the cohomology ring $H^{*}(P E)$ of the projective bundle, where the ring was considered as an algebra over
$H^{*}(M)$. This somewhat ad hoc procedure turned out to yield all characteristic classes of $E$ only after we learned that all bundles of a given rank were pullbacks of a universal bundle and that the cohomology ring of the universal base space (the classifying space) was generated by the Chern classes of the universal bundle.

From a purely topological point of view one could therefore dispense with the original definition, for by designating a set of generators of the cohomology ring of the classifying space as the universal Chern classes, one can define the Chern classes of any vector bundle simply as the pullbacks via the classifying map of the universal Chern classes. On the other hand, from the differential-geometric point of view the projective-bundle definition is more appealing, starting as it does, with $c_{1}\left(S^{*}\right)$, a class that we understand rather thoroughly and that furnishes us with a canonical generator for $H^{*}(P E)$ over $H^{*}(M)$. However, this $c_{1}$ is taken on the space $P(E)$ rather than on $M$ and is therefore not directly linked to the geometry of $M$. The question arises whether one can write down a form representing $c_{k}(E)$ in terms of the following data:
(1) a good cover $\mathfrak{U}=\left\{U_{a}\right\}$ of $M$ which trivializes $E$;
(2) the transition functions

$$
g_{\alpha \beta}: U_{a} \cap U_{\beta} \rightarrow G L(n, \mathbb{C})
$$

for $E$ relative to such a trivialization;
(3) a partition of unity subordinate to the open cover $\mathfrak{U}$.

The answer to this question is yes and the reader is referred to Bott [2] for a thoroughgoing discussion. Here we will describe only the final recipe, for to understand it properly, we would have to explore the concepts of connections and curvature, which are beyond the scope of this book.

Observe first that we are already in possession of the desired formula for :he first Chern class of a complex line bundle $L$ (see (6.38)). Indeed, if $g_{\alpha \beta}$ is .he transition function for $L$, the element

$$
c^{1,1}=\frac{i}{2 \pi} d \log g_{a f}
$$

in the Cech-de Rham complex $C^{*}\left(\mathfrak{U}, \Omega^{*}\right)$ is both $d$ - and $\delta$-closed. By the collating formula (9.5), once a partition of unity is selected, this cocycle yields a global form. The cohomology class of this global form is $c_{1}(L)$.

In the general case one can construct a cocyle $\sum_{\substack{k=1 \\ k}}^{\substack{1 \\ k}} c^{k-q . k+q}$, with $c^{k-q . k+q}$ in $C^{k-q}\left(u, \Omega^{k+q}\right)$, that represents the $k$-th Chern class $c_{k}(E)$ by the following unfortunately rather formidable "averaging" procedure.

Let $I=\left(i_{0}, \cdots, i_{q}\right)$ correspond to a nonvacuous intersection, set

$$
U_{I}=U_{i_{0}} \cap \cdots \cap U_{i_{4}},
$$

and let

$$
g_{0 j}: U_{i_{0}} \cap U_{i j} \rightarrow G L(n, \mathbb{C})
$$

be the pertinent transition matrix function for $E$. Consider the expression

$$
\theta_{I}=\sum_{j=0}^{q} t_{j} g_{0 j}^{-1} d g_{0 j}
$$

as a matrix of 1 -forms on $U_{I} \times \mathbb{R}^{+1+1}$, the $t$ 's being linear coordinates in $\mathbb{R}^{+1}$. From $\theta$ one can construct the matrix of 2 -forms

$$
K_{I}=d \theta_{I}+\frac{1}{2} \theta_{I}^{2}
$$

on $U_{I} \times \mathbb{R}^{q+1}$ and set

$$
c_{A}(E)=\operatorname{det}\left(1+\frac{i}{2 \pi} K_{I}\right)
$$

Our recipe is now completed by the following ansatz. Let

$$
\Delta_{q}=\left\{\left(t_{1}, \cdots, t_{q+1}\right) \mid t_{j} \geq 0, \sum t_{j}=1\right\}
$$

be the standard $q$-simplex in $\mathbf{R}^{+1}$. The $2 k$-form $c_{r}^{k}(E)$ restricted to $U_{1} \times \Delta_{q}$, and integrated over the "fiber $\Delta_{q}$ " yields the desired form on $U_{s}$ :

$$
c_{1}^{k-q, k+q}(E)=\int_{\Delta_{1}} c_{d}^{k}(E) .
$$

In other words, $c_{k}(E)$ is represented by the chain

$$
\sum_{i=0}^{k-1} c^{k-\varepsilon, k+4} \in C^{*}\left(\mathbb{U}, \Omega^{*}\right) .
$$

Note that for dimensional reasons this chain has no component below the diagonal and also no component in the zero-th column. This fact has interesting applications in foliation theory (Bott [1]). In any case, the collating procedure (9.5) now completes the construction of the forms $c_{k}(E)$ in terms of the specified data.

## List of Notations*

| $\Omega_{+}^{*}(M)$ | de Rham complex with compact supports 18 |
| :---: | :---: |
| $H_{c}^{*}(M)$ | compact de Rham cohomology 18 |
| $\boldsymbol{M}-\mathbf{P}-\boldsymbol{Q}$ | complement of P and Q in M 19 |
| $\operatorname{Hom}(A, B)$ | homomorphisms from $A$ to $B \quad 20$ 促 |
| $1 /$ | identity map from $A$ to $A 20$ |
| $U \cap V$ | intersection 20 |
| Gap | transition function 20，48 |
| $\partial f / \delta x_{1}$ | partial derivative 21 |
| $\left\{p_{a}\right\}_{\text {eal }}$ | partition of unity 21 |
| $\boldsymbol{U} \cup \boldsymbol{V}$ | union 22 |
| $U$ UV | disjoint union 22 |
| $S^{\mathbf{n}}$ | n－sphere 24， 36 |
| coker | cokernel 24 |
| $M \times N$ | Cartesian product 26 |
| $j_{\text {F }}$ | extension by zero 26 |
| $\pi_{*}$ | integration along the fiber 37 |
| $e_{*}$ | wedge with e 38 |
| $f_{*}$ | induced map on tangent spaces 42 induced map on homotopy groups 149， 209 induced map on homology groups 219 |
| $\gamma_{*}$ | action of $\boldsymbol{\pi}_{1}$ on $\boldsymbol{\pi}_{\mathbf{4}} \mathbf{2 1 0}$ |
| $\int_{m} f\left\|d x_{1} \cdots d x_{n}\right\|$ | Riemann integral 27 |
| $\left(x_{1}, \ldots, x_{n}\right)$ | point in $\mathrm{P}^{\mathbf{\prime \prime}} 28$ |
| $\operatorname{sgn} \pi$ | sign of a permutation 28 |
| $J(T)$ | Jacobian determinant det $\left(\partial x_{*} / \partial y_{j}\right) 28$ |
| ［M］ | orientation on M 29 |
| дM | boundary of M $\mathbf{3 0}$ |
| $\mathbf{H a}^{\text {a }}$ | upper half space 30 |
| $\left.\omega\right\|_{s}$ | restriction of a form to a subset 31 |
| $\boldsymbol{K}$ | homotopy operator 34，94 |
|  | differential complex 90 |
|  | simplicial complex 142 |
|  | cone construction 184 |
| $\\|$ | length of a vector 36，123 |
| U， $\boldsymbol{B}$ | open covers 42，43 |
| 〈，〉 | Riemannian structure 42 |
| $\boldsymbol{u}>\boldsymbol{B}$ | $\mathfrak{U}$ is refined by $\mathfrak{B} 43$ |
| $V^{*}$ | dual of a vector space 44 |
| $\Pi$ | direct product 46 |
| $\left.E\right\|_{s}$ | restriction of a vector bundle to a subset 47 |
| $\operatorname{Diff}(F)$ | diffeomorphism group 48 |
| G | inclusion map 50 |
| ［ $\eta_{s}$ ］ | Poincaré dual of $S 51$ |
| GL（ $n, R$ ） | real general linear group 53 |

| $G L(m, C)$ | complex general linear group 54 |
| :---: | :---: |
| $\Gamma(U, E)$ | group of sections of a vector bundle over $U 54$ |
| $G L^{+}(\boldsymbol{m}, \mathbf{R})$ | $n$ by $n$ real matrices with positive determinant |
| $T_{M}$ | tangent bundle of a manifold 55 |
| $T_{x} M$ | tangent space to $M$ at the point $x$ SS |
| $O(n)$ | orthogonal group 55 |
| SO(n) | special orthogonal group ${ }^{3} 55$ |
| $f^{\prime}$ | transpose 56 |
| $f^{-1} E$ | pullback bundle 56 |
| Vect ${ }_{\text {L }}(\mathbf{M})$ | isomorphism classes of real rank $k$ vector bundles 57 |
| Vect ${ }_{\text {L }} \mathbf{M}$; C $)$ | isomorphism classes of complex rank $k$ vector bundles 299 |
| Iso( $V, W$ ) | isomorphisms from $V$ to $W 57$ |
| $D(f)$ | Jacobian matrix 60 |
| $\mathbf{\Omega}_{\text {co }}^{*}(E)$ | forms with compact support in the vertical direction 61 |
| $H_{c v}^{*}(E)$ | compact vertical cohomology 61 |
| 5 | Thom isomorphism 64 |
| $\Phi(E)$ | Thom class of an oriented vector bundle .64,65 |
| $N_{S / M}$ | normal bundle of S in M 66 |
| $T$ | tubular neighborhood 66 |
| codim | codimension 69 |
| $\psi$ | angular form 70,71, 121 |
| $E^{0}$ | complement of the zero section of a vector bundie 71 |
| $e(E)$ | Euler class 72,117 |
| $C P^{\text {m }}$ | complex projective space 75 |
| $C P^{\text {c }}$ | infinite complex projective space 242 |
| C | complex $n$-space 53 |
| $\left[z_{0}, \ldots, z_{n}\right]$ | homogeneous coordinates on complex projective space 75 |
| $[a, b]$ | closed interval from $a$ to $b 18$ |
| $(a, b)$ | open interval from $a$ to $b$ <br> point in $\mathbf{R}^{2} 151$ |
|  | bidegree 164 |
|  | greateat common divisor 194 |
| $\Omega^{*}(\Omega)$ | relative de Rham complex 78 |
| $H^{*}(f)$ or $H^{(M, S}(\mathbb{S})$ | relative de Rham cohomology 78,79 |
| $H^{4}(f)$ | induced map in cohomology 261 |
| $\mathrm{A}^{4} \mathrm{E}$ | exterior power 80, 278 |
| $\boldsymbol{\Omega}^{\boldsymbol{*}}(\mathbf{M}, E)$ | difierential forms with values in a vector bundle 79 |
| $\boldsymbol{\Omega}(M, E), d$ | complex of E-valued forms relative to a trivialization 80 |
| $\operatorname{sgn}$ | sign function 84 |

| 314 | List öf Notations |
| :---: | :---: |
| $L$ | orientation bundle 84 |
| $\Lambda^{n} T_{*}^{*} \otimes L$ | density bundle 85 |
| $C^{*}\left(\mathfrak{U}, \Omega^{*}\right)$ | Cech-de Rham complex 89 |
| $\delta$ | difference operator $90,93,110$ Cech boundary operator 186 |
| D | differential operator on the Cech-de Rham complex 90,95 |
| $D^{\prime \prime}$ | $(-1)^{p} d 90$ |
| $H_{D}\left\{C^{*}\left(\underline{U}, \Omega^{*}\right)\right\}$ | Cech-de Rham cohomology 91 |
| $r$ | restriction 91 |
| $U_{\alpha \beta}$ | pairwise intersection 92 |
| $U_{a \beta y}$ | triple intersection 92 |
| $\partial_{i}$ | inclusion 92 |
|  | component of $\omega 93$ |
| $C^{*}(\mathfrak{U}, \mathbb{R})$ | Cech complex with coefficients in the constant presheaf $\mathbb{R} 97$ |
| $H^{*}(\mathfrak{U}, \mathbb{R})$ | Cech cohomology of an open cover 97 |
| $N(\mathfrak{U})$ | nerve of a cover 100 |
| RP ${ }^{\text {a }}$ | real projective space 77, 105, 241 |
| $\pi^{-1} \mathfrak{U}$ | inverse cover 106 |
| $\rho_{V}^{U}$ | restriction from $U$ to $V 109$ |
| Open ( $X$ ) | category of open sets and inclusions 109 |
| $\mathscr{H}^{q}, \mathscr{H}^{q}(F)$ | cohomology presheaf of a fibration 109 |
| $C^{p}(\mathfrak{U}, \mathscr{F})$ | $p$-chains on an open cover with values in a presheaf 110 |
| $H_{\delta} C^{*}(\mathfrak{U}, \mathscr{F})$ or $H^{*}(\mathfrak{U}, \mathscr{F})$ | Cech cohomology of an open cover 110 |
| $H^{*}(X, \mathscr{F})$ | Cech cohomology 110 |
| $S(E)$ | unit sphere bundle 114 |
| $\operatorname{det} E$ | determinant bundle 116 |
| $\stackrel{\varepsilon}{\Sigma}$ | Cech cocycle representing the Euler class 116 |
| $\sum$ | sum 116 |
| $\chi(M)$ | Euler characteristic 126 |
| $\Delta$ | diagonal 127 |
| $C^{*}\left(\pi^{-1} \mathfrak{U}, \Omega_{c v}^{*}\right)$ | Cech-de Rham complex with compact vertical supports 130 |
| $H^{\text {P }}{ }^{\text {q }}$ | elements of degree ( $p, q$ ) in d-cohomology 130 |
| $\mathscr{H}^{\underline{q}}{ }_{\text {c }}$ | compact vertical cohomology presheaf 130 |
| $\mathscr{H}^{\text {c }}$ | compact cohomology functor 141. |
| $K^{\prime}$ | first barycenfric subdivision of a simplicia! complex 142 |
| $\pi_{1}(K)$ | edge path group of a simplicial complex 146 |
| $\pi_{1}(X)$ | fundamental group of a topological space 147 |
| $\|K\|$ | support of a simplicial complex 142 |
| $\mathrm{N}_{2}(1){ }_{2}$ | 2-skeleton of nerve " 148 |
| $S^{1} \vee S^{2}$ | wedge 153,262 |

Czech cohomolugy
is isomorphic to the Cech-de Rham cohomology 98
is isomorphic to the de Rham cohomology 98, 104, 112
is the same for all good covers 99
of a circle 100
of an open cover 97,99,110
of a space 112
with values in a presheaf 110
Čech-de Ram complex 96
Cech-de Ram isomorphism
as an application of the Mayer - Vietoris principle 98
as graded algebras 175
explicit formula for 104
spectral sequence proof of 166
tic-tac-toe proof of 138
Cech-singular complex
in cohomology 190
in homology 196. 197
Chain homotopic 34
Chain-homotopy inverse 104
Chain map 17
Characteristic classes 8, 266 (See also Chern classes; Euler class; Pontrjagin classes)
Churn classes 267,270. 304
are the only cohomological invariants of a complex vector bundle 299
as generators of the cohomology ring of a Grassmannian 29.3
first Chen class 267
in terms of the patching data 304
naturality 271
of a complex projective space 281
of a direct sum 272
of a hypersurface 282
of a symmetric power 279
of a tensor product 279
of a trivial bundle 271
of an exterior power 278. 279
of the dual bundle 280
top Chern class is the Euler class 272, 278
universal Chern classes 304
Whitney product formula 272, 275
Churn, Shing-shen 8. 266
Circle
as an Eilenberg - MacLane space 240

Structure group 47
of a complex vector bundle $54 ; 267$
of a fiber bundie 47 is:

Structure group (cons.)
of a real vector bundle 53
of a sphere bundie 113
of an orientable vector bundle 55
reduction of (See Reduction of the structure group)
Subcomplex 156
Subdivision
barycentric 142
Sullivan, Dennis 259, 263
Support
of a form 24
of a function 18
of a simplicial complex 142
Surface with boundary 231
Sylvester's theorem 220
Symmetric function theorem 278
Symmetric power 279
Chern classes of 279

## Tangent bundle 55

holomorphic tangent bundle 280
of a sphere (See Tangent bundle of a sphere)
Tangent bundle of a sphere
cohomology 194
Euler class 125
unit tangent bundle of the 2 -sphere is SO(3) 195
Tangent space 21
Tangent vector field (See Vector field)
Tautological exact sequence
over a Grassmaninian 292
over a projective bundie 270
over a projective space 268
Telescoping construction. 241
infinite complex projective space
infinite Grassmannian 302
infinite Lens space 243
infinite real projective space 241
infinite sphere 242
Tensor product
exactmess 169
Chern classes of 267, 279
of vector bundles 56
product structure 176
Thom class 64, 232
a characterization of 64
as a relative cohomology class 78
in terms of the global angular form 74, 132
in terms of the patching data 75
of a direct sum 65
pulls back to the Euler class 74, 132
relation to the Poincaré dual 67
Thom isomorphism 63
and Poincaré duality 60 ;
nonorientable 88,131
3 -sphere 243
$\pi_{4}\left(S^{3}\right) \quad 251$
$\pi_{5}\left(S^{3}\right) \quad 257$
Tic-tac-toe lemma 135
Tic-tac-toe proof
of Poincaré duality 141
of the generalized Mayer-Vietoris principle 138
of the Künneth formula 105
of the Leray-Hirsch theorem 108
Todd class 279
Tor functor 193, 194
Torsion 9, 182, 194
Torus 221
good cover on 105
Total space 48
Total Chern class 270 (See also Chern classes)
Total Pontrjagin class 289 (See also
Pontrjagin classes)
of a complex manifold 290
of a sphere 290
Transition functions
for a fiber bundle 48
for a manifold 20
for a vector bundle 53
for the conjugate bundle 286
for the density bundle 85
for the direct sum 56
for the dual bundle 56
for the tensor product 56
reduction of the structure group 54
242 Transgression 247
Transgressive element 247
Transversal intersection 68,69
codimension is additive 69
is dual to the wedge product 69
normal bundle of 69
Transversality theorem 123
Triangularizable space 190
good covers are cofinal 190
Triangulation 190
of a manifold 190
Tricks
basic tricks in homotopy theory 249
Trivial presheaf 109
Trivialization
and transition functions 54
of a coordinate open cover $21^{*}$ locally constant 80
Tubular neighborhood 65, 214
Tubular neighborhood theorem 66
Twisted cohomology 80,82
and trivialization 80,83
invariant under the refinement of open covers 82
Twisted de Rham cohomology 84
is the same as the de Rham cohomology on an orientable manifold 85
Twisted de Rham cohomology with compact supports 84
Twisted de Rham complex 85

Unit sphere bundle 114
Unit tangent bundle of a sphere cohomology of 195
Unitary group 196, 292 integer cohomology of 196
reduction of the structure group to
stable homotopy groups of 239
Universal Chern classes 304
Universal coefficient theorems 194
Universal covering 252
of a circle. 152
Universal quotient bundle
and the cohomology of a Grassmannian 293
classification of vector bundles 298
over a Grassmannian 292, 298
over a projective bundle 270
over a projective space 268
Universal subbundle 77,270
over a Grassmannian 292
over a projective bundle 270
over a projective space 268
Upper half space 30
n-small chain 185

Vector bundles (See also oriented vector bundle)
classification 299
cohomology 60
compact cohomology 60,65
compact vertical cohomology 61,63
complex vector bundle 54
Euler class 72, 118
exact sequence of 65
flat $\mathbf{8 0}$

God-given 268
isomorphic $\Longleftrightarrow$ cocycles are. equivalent 54
orientability of 54
orientable $\Longleftrightarrow$ associated sphere bundles are 115
orientable $\Longleftrightarrow$ determinant bundles are 116
over a contractible manifold 59.
over a simply connected manifold 116
over a sphere 302
real vector bundle 53
reduction of the structure group 54,267
splitting of 274
to "dilute" a vector bundle 291
unit sphere bundle of 114
Vector field 21
Hopf index theorem 129
index of a zero 128
on a sphere 125
Volume integral 3
Volume form
on a sphere 27
on the 2 -sphere 235

Wedge of spheres 153,262
minimal model 263
ranks of the homotopy groups 265
Wedge product of differential forms 14
is Poincaré dual to a transversal intersection 69

- Weil, André 5, 10, 89

Whitehead tower 252, 253, 257
Whitney embedding theorem 213
Whithey, Hassler 7, 217, 266
Whitney product formula
for the Chern class 272, 275
for the Euler class 133
for the L-class 279
for the Pontrjagin class 289
for the Todd class 279

Yang-Mills 8

Zero locus of a section
normal bundle of 133
orientation on 134
Poincaré dual of 134
Zig-zag 95

## Interdependence of the Sections

[^0]:    *: In fact two manifolds have the same homotopy type in the $C^{\infty}$ sense if and only if they have the same homotopy type in the usual (continuous) sense. This is because every continuous map between two manifolds is continwously hopaotopic to a $C^{\infty}$ map (see Proposition 17,8).

[^1]:    * However, a locally constant sheaf on a simply connected space is constant.
