HOMOTOPY THEORETIC CONSEQUENCES OF N. LEVITT’S OBSTRUCTION THEORY TO TRANSVERSALITY FOR SPHERICAL FIBRATIONS

GREGORY W. BRUMFIEL AND JOHN W. MORGAN

The main goal of this paper is a detailed analysis of the problem of imposing a topological bundle structure on a spherical fibre space over a simply connected base. The method involves a careful study of the notion of fibre homotopy transversality due to N. Levitt. The point is, a topological disc bundle satisfies strong transversality properties for maps from manifolds to the associated Thom space. These properties can be formulated at least for spherical fibre spaces. Thus, obstructions to transversality can be interpreted as obstructions to imposing a topological bundle structure on a spherical fibre space. It turns out that over a simply connected base the obstructions to transversality coincide exactly with the obstructions to a topological structure.

The obstructions to transversality for a spherical fibre space $\xi$ can be interpreted as obstructions to a deformation of the identity map on the Thom space $T_\xi$ to a certain subcomplexes $W_\xi$. The fibre of the map $W_\xi \to T_\xi$ is a space with a suitable iterated loop space homotopy equivalent to $G/\text{TOP}$. The total obstruction to transversality becomes the obstruction to a $\text{KO}_{\mathbb{Z}}$ orientation of the Thom space $T_\xi$, mixed with certain cohomology classes of $T_\xi, \xi \in H^{n+1}(T_\xi, \mathbb{Z}_2)$ and $\xi \in H^{n+1}(T_\xi, \mathbb{Z}/2)$. These obstructions are then also interpretable as the obstructions to lifting in the fibration sequence $G/\text{TOP} \to \text{BSTOP} \to \text{BSG}$.

In this introduction, we give a rather detailed outline of our results and describe the relationship with work of others, particularly, N. Levitt [10], F. Quinn [18], and L. Jones [8]. Suppose that $\pi: \xi \to B_\xi$ is a spherical fibre space, with Thom space $T_\xi$, and let $f: M \to T_\xi$ be a map from a PL manifold to $T_\xi$. The primary question is, very roughly, when can one deform $f$, so that $f^-(B_\xi) \subset M$ is a Poincaré duality space?

If $\xi \to B_\xi$ is a (block) PL sphere bundle, the answer is always. In fact, in this case we may deform $f$ so that $L = f^-(B_\xi) \subset M$ is a PL submanifold of $M$, with a tubular neighborhood $V = f^-(D_\xi)$, where $D_\xi$ is the associated PL block bundle of $\xi$. $V$ is a block bundle over $L$ and $f$ induces a bundle map.
Note that $V$ itself is Poincaré duality space, homotopy equivalent to $L$, and the inclusion of the boundary $\partial V \subset V$ is, up to homotopy, a spherical fibration.

These considerations lead one to a correct definition of transversality if $\pi: \xi \to B\xi$ is only a spherical fibration. Namely, let $\mathcal{M}\xi = \xi \times I \cup_{\xi \times \{0\}} B\xi$ be the mapping cylinder of $\pi: \xi \to B\xi$. (If $\xi$ is an honest sphere bundle, $\mathcal{M}\xi$ is the associated disc bundle $D\xi$.) Then $T\xi = \mathcal{M}\xi \cup_{\xi} C\xi$, where $C\xi$ is the cone on $\xi$.

**Definition (approximate).** $f: M \to T\xi$, $M$ a closed manifold, is **globally Poincaré transversal** if the inclusion $f^{-1}(\xi) \subset f^{-1}(\mathcal{M}\xi)$ is a spherical fibration, induced by $f$ from $\xi \subset \mathcal{M}\xi$.

If $\xi^q$ has fibre $S^{q-1}$ and $M$ has dimension $q + i$, the definition implies that $f^{-1}(\mathcal{M}\xi)$ is a Poincaré duality space (PD space) of formal dimension $i$. There is an analogous definition if the manifold $M$ has a boundary; in this case, $(f^{-1}(\mathcal{M}\xi), f^{-1}(\mathcal{M}\xi) \cap \partial M)$ is a PD space with boundary.

Now the theory of Levitt states that if $B\xi^q$ is 1-connected, $q \geq 3$, there is an Eilenberg-MacLane obstruction theory, with obstructions in $H^{q+i+1}(M, Q_i)$, to deforming $f: M \to T\xi^q$ to a transversal map, where (at least if $i > 4$) the group $Q_i$ is isomorphic to the surgery obstruction group

$$P_i = \mathbb{Z}, 0, \mathbb{Z}/2, 0 \quad \text{as} \quad i \equiv 0, 1, 2, 3 \pmod{4}.$$  

Quinn's theory of surgery on PD spaces implies that if $M$ has dimension $q + j + 1$, there is a single obstruction, in $P_j$ to deforming $f: M \to T\xi^q$ to a transversal map. This discrepancy is easy to explain. By "transversal map," Levitt means that $M$ is triangulated such that for each simplex $\Delta \subset M$, $f|_\Delta: \Delta \to T\xi^q$ is Poincaré transversal, whereas Quinn uses "transversal map" in the global sense of the definition above. One problem which interested us then was whether we could identify a global, "top" obstruction in the context of Levitt's cell-by-cell obstruction theory. We do define a global obstruction to transversality, using the Levitt theory, much as one picks out the surgery obstruction from all the invariants of a normal map. However, the methods of this paper only enable us to prove that this top obstruction is the obstruction to cobording (rather than homo-
toping) a map \( f: M \to T_ξ \) to a transversal map. Our obstruction does agree with Quinn's, however, and thus from his theory it follows that it is the obstruction to homotoping \( f \) to a globally transversal map.

A second problem was to extend the results of Levitt and Morgan [11] relating Poincaré transversality and topological structures on a spherical fibration \( ξ \). They prove (roughly) that if the base space \( B_ξ \) is 4-connected and if every map \( f: M \to T_ξ \) can be made Poincaré transversal, then \( ξ \) admits a topological structure. In fact, there is a \( 1 - 1 \) correspondence between topological structures on \( ξ \) and "Poincaré transversality structures" on \( ξ \). We extend these results to 1-connected base spaces. A homotopy theoretic reformulation of these geometric results gives that at odd primes \( p \), a topological structure on \( ξ \) is equivalent to a \( KO \otimes Z_p \)-theory orientation of \( T_ξ \), (this is a well-known theorem of Sullivan [23]) and at \( p = 2 \), a topological structure is equivalent to null-homologies of certain stable cohomology characteristic classes of \( ξ \), \( \tilde{\mathcal{H}}(ξ) \in H_4^*(B_ξ, Z/2) \) and \( \tilde{\mathcal{D}}(ξ) \in H_4^{*+1}(B_ξ, Z_{(2)}) \). Similar results were proved by Quinn [Q1, Q2]; the \( p = 2 \) results have also been proved by Madsen and Milgram [12] and Jones [8]. A very precise definition of the classes \( \tilde{\mathcal{H}}(ξ) \) and \( \tilde{\mathcal{D}}(ξ) \) and a detailed study of their properties accounts for much of the bulk of the present paper.

Our third main problem was to understand the relations between the top obstruction to Poincaré transversality in dimensions \( 4n + 1 \) and the index of Poincaré duality spaces. We prove, for example, that the obstruction \( \tilde{\mathcal{D}}(ξ) \in H_4^{*+1}(B_ξ, Z_{(2)}) \) to a topological structure (or to Poincaré transversality, since these are the same) is the Bockstein (for the coefficient sequence \( 0 \to Z_{(2)} \to Z_{(2)} \to Z/8 \to 0 \)) of a characteristic class \( l(ξ) \in H_4^*(B_ξ, Z/8) \). Among the properties of \( l(ξ) \) is this: if \( K^\infty \) is a \( 4n \)-dimensional PD space and \( ν_κ \) is its stable normal spherical fibration, then \( \langle l(ν_κ) \rangle, [K] \rangle = \text{index}(K) (\text{mod} 8) \). (The existence of such a class was shown by D. Frank, also using Levitt's theory of transversality. We gives additional properties of \( l(ξ) \) which characterize it uniquely.) The result \( \tilde{\mathcal{D}}(ξ) = βl(ξ) \) is intimately related to the theorem of Morgan and Sullivan [15] that there is a \( Z_{(2)} \) characteristic class \( L(ξ) \in H_4^*(B_ξ, Z_{(2)}) \) of topological bundles \( ξ \), which measures the index in \( Z \) of topological manifolds. \( L \) is defined using topological transversality, and reduces modulo 8 to our class \( l(ξ) \). The connection is clear: if one has enough transversality, the \( Z/8 \) index class \( l(ξ) \) lifts to a \( Z_{(2)} \) index class \( L(ξ) \), which gives a homology of \( \tilde{\mathcal{D}}(ξ) = βl(ξ) \) to 0.

We now begin a more detailed outline of the individual sections of the paper. Chapter I, consisting of the first four sections, contains
the geometric machinery and results of the paper. In §1 we develop a modified version of the Levitt obstruction theory. Namely, we strengthen the definition of a Poincaré transversal $q + 2$ simplex, $f : \Delta^{q+2} \to T_\xi^q$, by adding the condition that $f^{-1}(\mathcal{M}_\xi) \subset \Delta^{q+2}$ have the homotopy type of a 2-manifold with boundary. In other dimensions, the definition is unchanged. It is an old conjecture [24] that all 2-dimensional PD spaces are homotopy equivalent to manifolds. If this is true, our obstruction theory agrees with Levitt's. The advantage of the stronger definition is that it is possible to compute the obstruction groups in all dimensions, whereas Levitt's low dimensional obstruction groups were unknown.

The fundamental lemma in §1 is the following local result.

**THEOREM A.** Suppose that the spherical fibration $\xi^q$ admits a PL structure, $q \geq 3$, $\pi_1(B_\xi^q) = 0$, and let $f : D^{q+i+1} \to T_\xi^q$ be a map such that $f|_{S^q} : S^{q+i} \to T_\xi^q$ is Poincaré transversal. Assume further that if $i = 2$, $f^{-1}(\mathcal{M}_\xi) \cap S^{q+i}$ is homotopic to a 2-manifold. Then there is a well-defined obstruction $\alpha(f) \in P_i$ such that $f$ deforms rel $\partial D$ to a Poincaré transversal map if and only if $\alpha(f) = 0$.

$\alpha(f) \in P_i$ is the surgery obstruction of a degree one normal map $L' \to L$, where $L'$ is an $i$-dimensional PL manifold and $L$ is an $i$-dimensional PD space. Namely, $L = f^{-1}(\mathcal{M}_\xi) \cap S^{q+i}$, and $L' \subset L$ is obtained by deforming $f : D^{q+i+1} \to T_\xi^q$ slightly to a PL transversal map, keeping $f^{-1}(\mathcal{M}_\xi)$ setwise fixed.

Using the local result, we set up an obstruction theory, with obstructions in $H^{q+i+1}(M, P_i)$, to deforming a map $f : M \to T_\xi^q$ to a strongly transversal map, where $\xi^q$ is any spherical fibre space with simply connected base. The idea is, we may cover the base $B_\xi^q$ by simply connected, open sets $U_\alpha$, all containing the base point such that $\xi^q|_{U_\alpha}$ admits a PL structure. This induces a cover $\{V_\alpha\}$ of $T_\xi^q$, and our first step is to triangulate $M$ such that for each simplex $\Delta \subset M$, $f(\Delta) \subset V_\alpha$ for some $\alpha$. If $f$ is strongly transversal on the $q+i$ skeleton of $M$, the local result enables us to define an obstruction cocycle in $C^{q+i+1}(M, P_i)$, which vanishes if and only if $f$ deforms rel the $q+i$ skeleton to a map which is strongly transversal on the $q+i+1$ skeleton.

In §2 we reformulate the obstruction theory. Specifically, let $W_\xi^q$ be the subcomplex of the singular complex of $T_\xi^q$ consisting of simplexes $f : \Delta^{q+i} \to T_\xi^q$ which are Poincaré transversal, with $f(\Delta^{q+i}) \subset V_\alpha$, some $V_\alpha \subset \{V_\alpha\}$, and with $f^{-1}(\mathcal{M}_\xi) \subset \Delta^{q+i}$ homotopic to a 2-manifold if $i = 2$. As a corollary of the obstruction theory of §1, we deduce

$$\pi_{q+i+1}(T_\xi^q, W_\xi^q) \to P_i.$$
In fact, the obstructions to deforming $f: M \to T_\xi^\ast$ to a strongly transversal map can be interpreted as the obstructions to lifting $f$ to a map $\tilde{f}$ in the diagram

$$
\begin{array}{ccc}
W_\xi & \longrightarrow & T_\xi^{\ast} \\
\downarrow f & & \downarrow f \\
M
\end{array}
$$

The space $W_\xi$ was also studied by Levitt, without the extra condition on $q + 2$ simplexes. Our space $W_\xi$ is more natural for studying topological structures on $\xi^i$, since if $\xi^i$ is a topological bundle, topological transversal simplexes $A^{i+1} \to T_\xi^\ast$ clearly belong to $W_\xi$. On the other hand, Levitt's original space was more closely related to Poincaré duality cobordism, the problem he was studying at the time.

Let $F_\xi$ be the fibre of the natural map $W_\xi \to T_\xi^{\ast}$. In §2 we also define very powerful homomorphisms on the $\mathbb{Z}/n$ bordism of $F_\xi$, $n \geq 0$,

$$
\mathcal{O}_\ast: \Omega_{x+1}(F_\xi, \mathbb{Z}/n) \longrightarrow P, \otimes \mathbb{Z}/n.
$$

(A $\mathbb{Z}/n$ manifold is an oriented manifold $M$, together with an orientation preserving isomorphism of the boundary of $M$ with $n$ disjoint copies of a manifold $\partial M$, $\phi: \coprod_n \partial M \cong \partial M$. A $\mathbb{Z}/0$ manifold is thus a closed, oriented manifold. $\partial M$ is called the Bockstein of $M$; a $\mathbb{Z}/n$ bordism element must map the $n$ copies of the Bockstein equivariantly.) To define $\mathcal{O}_\ast$, we first give a geometric interpretation of bordism elements of $F_\xi$. Namely, $\varphi: M \to F_\xi$ corresponds to a strongly transversal map $f: M \to T_\xi^\ast$, together with a homotopy $F: M \times I \to T_\xi^\ast$ from $F_0 \equiv f$ to $F_1 \equiv \infty$, $\infty \in T_\xi^\ast$ the cone point. Using the obstruction theory of §1, we show that if $M^{i+1}$ is a $\mathbb{Z}/n$ manifold, there is a well-defined obstruction $\mathcal{O}_\ast[M, \varphi] \in P, \otimes \mathbb{Z}/n$ to deforming $F: M \times I \to T_\xi^\ast$, rel $M \times \partial I$, to a globally transversal map. $\mathcal{O}_\ast[M, f]$ is (not surprisingly) the surgery obstruction of a degree one normal map $L' \to L$, where $L'$ is a $\mathbb{Z}/n$ PL manifold and $L$ is a $\mathbb{Z}/n$ PD space.

To see how these surgery problems arise, suppose first that $\xi^i$ admits a PL structure. Shift $F: M \times I \to T_\xi^\ast$ slightly to a PL transversal map, $G$, keeping $F^{-1}(\mathbb{M} \xi^i)$ setwise fixed. Then $L' = G^{-1}(B^{i+1}(\peri{\xi}^i) \cap M \times \{0\}) \subset G^{-1}(\mathbb{M} \xi^i) \cap M \times \{0\} = F^{-1}(\mathbb{M} \xi^i) \cap M \times \{0\} = L$ is a degree one normal map.

If $\xi^i$ is an arbitrary special fibre space, we use the obstruction theory to produce a normal map. Namely, since $H^\ast(M \times I, M \times \{0\})=0$, we may deform $F$ rel $M \times \{0\}$ to a strongly transversal map $G: M \times I \to T_\xi^\ast$, such that $G_{|_{M \times \{1\}}}: M \times \{1\} \to T(\xi^i|_0)$, where $U$ is a contractible neighborhood of the basepoint of $B^{i+1}(\peri{\xi}^i)$. (See Chapter I for details.)
Moreover, \( G|_{M \times \{1\}} : M \times \{1\} \to T(\xi_q|_U) \) is homotopic to the constant map \( \infty, \infty \in T\xi_q \), since \( G \) is the deformation of \( F \). Now \( \xi_q|_U \) admits a \( PL \) structure since \( U \) is contractible, hence we apply the construction of the paragraph above to \( G|_{M \times \{1\}} \) to obtain a normal map.

We point out that if \( \xi_q \) admits a \( PL \) structure, the normal map produced by this general construction is cobordant to the normal map produced directly from \( PL \) transversality. Thus the surgery obstruction is well defined.

The resulting homomorphisms \( \sigma_n : \Omega_{q+i}(F_{\xi_q}, Z/n) \to P_i \otimes Z/n \) satisfy properties essentially identical to the properties of the classical surgery obstruction homomorphisms of Sullivan;

\[
S_n : \Omega_q(G/TOP, Z/n) \to P_i \otimes Z/n .
\]

The most important properties are (i) the composition

\[
\pi_{q+i}(F_{\xi_q}) \to \Omega_{q+i}(F_{\xi_q}) \to P_i
\]

is an isomorphism and (ii) \( \sigma_n \) satisfies a multiplicative formula like those of [15] with respect to the index; that is, if \( \phi : M^{q+i} \to F_{\xi_q} \) is a \( Z/n \) bordism element and \( N^i \) is a \( Z/n \) manifold, then

\[
\sigma_n[M^{q+i} \times N^i, \phi \pi_i] = \sigma_n[M^{q+i}, \phi \cdot \text{index}(N^i)] .
\]

(See [15] for a definition and properties of the "product" \( M^{q+i} \times N^i \) of \( Z/n \) manifolds.)

Just as Sullivan showed that the surgery obstruction homomorphisms \( S_n : \Omega_q(G/TOP, Z/n) \to P_i \otimes Z/n \) completely determine the homotopy type of \( G/TOP \), we show in §5 that the obstructions \( \sigma_n : \Omega_{q+i}(F_{\xi_q}, Z/n) \to P_i \otimes Z/n \) completely determine the homotopy type of \( F_{\xi_q} \). The result is that \( F_{\xi_q} \) is a copy of \( G/TOP \), shifted \( q \)-dimensions. (We will discuss this further below.)

These results of §2 were known earlier to Levitt and Morgan [11] for the \((q + 4)\)-connected cover of \( F_{\xi_q} \). The results of this paper simply extend their results, thanks to the stronger definition of transversality in dimension \( q + 2 \).

In §3 we define obstructions to global transversality, up to cobordism. The main idea is that, in the stable range, \( i \ll q \), there is an isomorphism

\[
\Omega_{q+i+1}(W_{\xi_q}, F_{\xi_q}, Z/n) \sim \tilde{\sigma}_{q+i+1}(T\xi_q, Z/n) .
\]

Composing the \( \sigma_n \) of §2 with the boundary homomorphism for the pair \( W_{\xi_q}, F_{\xi_q} \), thus defines homomorphisms

\[
s_n : \Omega_{q+i+1}(T\xi_q, Z/n) \to P_i \otimes Z/n ,
\]
for \( i \ll q, q \geq 3 \). We prove

**Theorem B.** If \( i \) is even (resp. \( i \) odd) and \( f: M^{q+i} \rightarrow T_{\xi}^{q} \) is a \( \mathbb{Z}/n \) manifold, then \([M, f]\) is \( \mathbb{Z}/n \)-bordant to a globally transversal map if and only if \( s_{n}[M, f] = 0 \in P_{i} \otimes \mathbb{Z}/n \) (resp. \( s(\delta M, f|_{\delta M}) = 0 \in P_{i-1} \)).

As remarked earlier, Quinn [18] has sharper results about these obstructions to global transversality, namely that these are the obstructions to homotoping \( f: M \rightarrow T_{\xi}^{q} \) to a globally transversal map.

As a corollary of Theorem B, note that any map \( f: M^{q+i} \rightarrow T_{\xi}^{q}, M \) closed, is cobordant to globally transversal map \( g: N^{q+i} \rightarrow T_{\xi}^{q} \). Let \( L^{s} = g^{-1}(\mathcal{M}_{\xi}) \subset N^{q+i} \) be the associated PD space. We prove in §3 the following.

**Lemma C.** Index \( (L^{s}) \in \mathbb{Z}/8 \) in an invariant of the bordism class of \([M, f]\).

Since there is a null-homotopic PD transversal map \( g: S^{q+i} \rightarrow S^{q} = T_{\xi}^{q} \), with \( g^{-1}(\mathcal{M}_{\xi}) = W^{q+i} \), where \( W^{q+i} \) is the almost parallelizable Milnor manifold of index 8, we see that the modulo 8 reduction of the index is the best invariant we can obtain from a transversal map \( g: N^{q+i} \rightarrow T_{\xi}^{q} \).

In §8 we generalize Lemma C to \( \mathbb{Z}/8 \) manifolds. Not all \( \mathbb{Z}/8 \) manifolds \( f: M^{q+i} \rightarrow T_{\xi}^{q} \) are cobordant to globally transversal maps, because of the obstruction \( s[\delta M, f|_{\delta M}] \in P_{q+i-2} = \mathbb{Z}/2 \), provided by Theorem B. However

**Lemma D.** If \( g: N^{q+i} \rightarrow T_{\xi}^{q} \) is a globally transversal \( \mathbb{Z}/8 \) manifold, and \( L^{s} = g^{-1}(\mathcal{M}_{\xi}) \subset N^{q+i} \) is the associated \( \mathbb{Z}/8 \) PD space, then index \( (L^{s}) \in \mathbb{Z}/8 \) is an invariant of the \( \mathbb{Z}/8 \) bordism class of \([N, g]\).

This is the main result we need to define \( \mathbb{Z}/8 \) characteristic class of spherical fibrations, which measures the index (mod 8) of PD spaces. (We will discuss this further below.)

In §4, we extend the main result of Levitt and Morgan [11] concerning the equivalence of topological structures on bundles \( \xi^{q} \) over 4-connected base spaces and liftings \( l \) in the diagram

\[
\begin{array}{ccc}
W_{\xi^{q}} & \longrightarrow & T_{\xi}^{q} \\
\downarrow & & \downarrow \text{Id} \\
T_{\xi}^{q} & \longrightarrow & T_{\xi}^{q}
\end{array}
\]
Our result is

**Theorem E.** If $\xi$ is a spherical fibration over a simply connected base, $q \geq 3$, then there is a natural bijection between equivalence classes of topological structures on $\xi$ and equivalence classes of lifting $l$ in the diagram

\[
\begin{array}{ccc}
W_\xi & \longrightarrow & T_\xi \\
\downarrow \ & \ & \downarrow \text{Id} \\
T_\xi & \longrightarrow & T_\xi .
\end{array}
\]

The proof breaks into two parts. The first part uses topological transversality to construct a lifting $l$ for a topological bundle $\xi$. This step is somewhat indirect since topological transversality cannot be assumed in codimension 4. We use a "crossing with $CP(2)$ trick" to overcome this difficulty. The second part of the proof essentially uses the fact that $G_q/\text{TOP}_q$ and $F_\xi$ are very closely related to establish that the map from topological structures on $\xi$ to liftings $l$ in the diagram is a bijective correspondence.

Chapter II, consisting of §§5 through 7, deals with homotopy theoretic consequences of the geometric results of Chapter I. In §5, we show how the homomorphisms \( \varphi_n : \Omega_{q+i}(F_\xi, \mathbb{Z}/n) \to P_{i} \otimes \mathbb{Z}/n \), $n \geq 0$, determine the homotopy type of $F_\xi$. In particular, the 2-localization of $F_\xi$ is a product of Eilenberg-MacLane spaces,

\[
(F_\xi)_{(2)} \cong \prod_{i \geq 1} K(\mathbb{Z}/2, q + 4i - 2) \times K(\mathbb{Z}/2, q + 4i) .
\]

The $p$-localization of $F_\xi$, $p$ odd, is a loop space of a connected cover of $BO(p)$. Except for computing the low dimensional homotopy groups of $F_\xi$, these results were proved in [11] by the same techniques.

The 2-localization result is equivalent to establishing a cohomological formula for $\varphi : \Omega_{q+i}(F_\xi) \to P_{i}$ and for $\varphi_r : \Omega_{q+i}(F_\xi, \mathbb{Z}/2^r) \to P_{i} \otimes \mathbb{Z}/2^r$, $r \geq 1$. Namely, we prove

**Theorem F.** There are unique cohomology classes

\[
\mathcal{X} = \sum_{i \geq 1} \mathcal{X}_{q+4i-2} \in H^{i+4i-2}(F_\xi, \mathbb{Z}/2)
\]

and

\[
\mathcal{L} = \sum_{i \geq 1} \mathcal{L}_{q+4i} \in H^{i+4i}(F_\xi, \mathbb{Z}_{(2)})
\]

such that given $f : M^{q+4i-2} \to F_\xi$, $M$ a $\mathbb{Z}/2$ manifold,

\[
\varphi_{i}[M, f] = \langle V^i(M) \cdot f^*(\mathcal{X}), [M] \rangle \in \mathbb{Z}/2
\]

and given $g : N^{q+4i} \to F_\xi$, $N$ a closed or a $\mathbb{Z}/2^r$ manifold,
\[ C_\ast[M, f] = \langle L(N) \cdot g^*(\mathcal{L}), [N] \rangle + i \langle VSq^i V(\delta M) \cdot g^*(\mathcal{K}), [\delta N] \rangle \in \mathbb{Z}/2^r \]

where \( i : \mathbb{Z}/2 \rightarrow \mathbb{Z}/2^r \) is the inclusion.

The formulae of Theorem F giving \( C_\ast : \Omega_{q+i-2}(F_\xi, \mathbb{Z}/2) \rightarrow \mathbb{Z}/2 \) in terms of \( \mathcal{K} \) and giving \( C_\ast : \Omega_{q+i}(F_\xi, \mathbb{Z}/n) \rightarrow \mathbb{Z}/n, n = 0 \) or \( 2^r \), in terms of \( \mathcal{L} \) and \( \mathcal{K} \), are identical to the formulae in [15] for the surgery obstruction homomorphisms \( S_\ast : \Omega_{i}(G/TOP, \mathbb{Z}/n) \rightarrow P_i \otimes \mathbb{Z}/n \) in terms of cohomology classes

\[ \mathcal{K} \in H^{*-i}(G/TOP, \mathbb{Z}/n) \quad \text{and} \quad \mathcal{L} \in H^i(G/TOP, \mathbb{Z}/n) \).

This is no accident, since the \( C_\ast \) are defined as surgery obstructions.

The proof of Theorem F is essentially given in the Appendix, where we give a detailed discussion of how homomorphisms on the bordism of a space can be used to define cohomology classes. The version we present is due to Sullivan, [23], although variants of the idea have been used earlier, (for example, in Thom's definition of rational Pontrjagin classes for PL manifolds). The classes \( \mathcal{K} \) and \( \mathcal{L} \) of Theorem F then define a homotopy equivalence

\[ \mathcal{K} \times \mathcal{L} : (F_\xi, \mathbb{Z}/2) \cong \prod_{i \geq 1} K(\mathbb{Z}/2, q + 4i - 2) \times K(\mathbb{Z}/2, q + 4i) . \]

From the cohomology exact sequence of the fibration \( F_\xi \rightarrow W_\xi \rightarrow T_\xi^q \) (in the stable range) we see that the classes \( \mathcal{K} \) and \( \mathcal{L} \) in the cohomology of \( F_\xi \) determine classes in the cohomology of \( T_\xi^q \). From the Thom isomorphism \( \phi : H^* (B_\xi^q) \rightarrow H^* (T_\xi^q) \), we get classes \( \tilde{\mathcal{K}}(\xi) \in H^{*-q}(B_\xi^q, \mathbb{Z}/2) \) and \( \tilde{\mathcal{L}}(\xi) \in H^{*+1}(B_\xi^q, \mathbb{Z}/2) \). Precisely, \( \phi(\tilde{\mathcal{K}}(\xi)) = \tau(\mathcal{K}) \) and \( \phi(\tilde{\mathcal{L}}(\xi)) = \tau(\mathcal{L}) \) where \( \tau : H^* (F_\xi) \rightarrow H^{*+1} (T_\xi^q) \) is the transgression, in the stable range, of the fibration \( F_\xi \rightarrow W_\xi \rightarrow T_\xi^q \).

The classes \( \tilde{\mathcal{K}}(\xi) \) and \( \tilde{\mathcal{L}}(\xi) \) are stable characteristic classes for spherical fibrations. From the definition of the global transversality obstructions \( s_\ast : \Omega_{q+i-1}(T_\xi^q, \mathbb{Z}/n) \rightarrow P_i \otimes \mathbb{Z}/n \), in terms of

\[ \mathcal{O}_\ast : \Omega_{q+i}(F_\xi, \mathbb{Z}/n) \rightarrow P_i \otimes \mathbb{Z}/n , \]

we obtain cohomological formulae for the \( s_\eta \) in terms of the classes \( \phi(\tilde{\mathcal{K}}(\xi)) \) and \( \phi(\tilde{\mathcal{L}}(\xi)) \): (see Theorem F above)

\[ s_2[M^{q+i-1}, f] = \langle V^2(M) \cdot f^* \phi(\tilde{\mathcal{K}}(\xi)), [M] \rangle \in \mathbb{Z}/2 \]

if \( f : M^{q+i-1} \rightarrow T_\xi^q \) is a \( Z/2 \) manifold, and

\[ s_\eta[N^{q+i+1}, g] = \langle L(N) \cdot g^* \phi(\tilde{\mathcal{L}}(\xi)), [N] \rangle + i \langle VSq^i V(\delta N) \cdot g^* \phi(\tilde{\mathcal{K}}(\xi)), [\delta N] \rangle \in \mathbb{Z}/2^r \]
if \( g: N^{r+1} \to T^r \) is a \( \mathbb{Z}/2 \) manifold. Here \( i: \mathbb{Z}/2 \to \mathbb{Z}/2 \) is the inclusion. We thus regard \( \overline{\mathcal{F}}(\xi) \) and \( \overline{\mathcal{L}}(\xi) \) as obstructions to global Poincaré transversality.

The main theorem of §6 is that, at the prime 2, \( \overline{\mathcal{F}}(\xi) \) and \( \overline{\mathcal{L}}(\xi) \) are the only obstructions to a topological structure on \( \xi \). More precisely, let \( \overline{\mathcal{F}} \in H^{r-1}(BSG, \mathbb{Z}/2) \) and \( \overline{\mathcal{L}} \in H^{r+1}(BSG, \mathbb{Z}/2) \) be the universal characteristic classes and let \( i: X \to BSG \) be the inclusion of the fibre of the map

\[
\overline{\mathcal{F}} \times \overline{\mathcal{L}} : BSG \longrightarrow \prod_{i \geq 1} K(\mathbb{Z}/2, 4i - 1) \times K(\mathbb{Z}/2, 4i + 1)
\]

**THEOREM G.** There is a commutative diagram

\[
\begin{array}{ccc}
X & \xrightarrow{i} & BSTOP_{(2)} \xrightarrow{B\pi} BSG_{(2)}
\end{array}
\]

with \( B\pi \) the natural map and \( i \) a homotopy equivalence.

Thus a lifting of \( \xi: Y \to BSG_{(2)} \) to \( \xi: Y \to BSTOP_{(2)} \) is equivalent to null-cohomologies of the characteristic classes \( \overline{\mathcal{F}}(\xi) \) and \( \overline{\mathcal{L}}(\xi) \).

F. Quinn has proved a theorem very similar to Theorem G, [19], [20]. In fact, his theorem is probably identical to Theorem G, but his definition of characteristic classes, corresponding to our \( \overline{\mathcal{F}} \) and \( \overline{\mathcal{L}} \), is rather abstract. I. Madsen and R.J. Milgram, [12], have also proved that \( BSTOP_{(2)} \) is the fibre of a map

\[
BSG_{(2)} \longrightarrow \prod_{i \geq 1} K(\mathbb{Z}/2, 4i - 1) \times K(\mathbb{Z}/2, 4i + 1)
\]

Namely, they prove that \( B(G/TOP)_{(2)} \) is a product of Eilenberg-MacLane spaces. The resulting cohomology classes of BSG are not identical to our \( \overline{\mathcal{F}} \) and \( \overline{\mathcal{L}} \), but they are closely related. At present, there is no geometric explanation of the connection between \( B(G/TOP) \), the classifying space for \( G/TOP \) with the Whitney sum structure, and Poincaré transversality. The transversality theory seems more closely related to a second \( H \)-space structure on \( G/TOP \). See also L. Jones [8] for a version of Theorem G.

In §7, we identify the suspensions of the cohomology classes \( \overline{\mathcal{F}} \) and \( \overline{\mathcal{L}} \); that is, \( \sigma(\overline{\mathcal{F}}) \in H^{r-1}(SG, \mathbb{Z}/2) \) and \( \sigma(\overline{\mathcal{L}}) \in H^{r}(SG, \mathbb{Z}/2) \), where \( \sigma: H^{r+1}(BSG) \to H^{r}(SG) \) is induced by the natural map \( \Sigma SG \to BSG \).

**THEOREM H.** \( \sigma(\overline{\mathcal{F}}) = \pi^{*}(\mathcal{F}) \) and \( \sigma(\overline{\mathcal{L}}) = \pi^{*}(\mathcal{L}) \), where \( \pi: SG \to G/TOP \) is the projection and \( \mathcal{F} \in H^{r-2}(G/TOP, \mathbb{Z}/2) \) and
Chapter III, which consists of §§8 and 9, gives the definition and properties of the $\mathbb{Z}/8$ index class $l = 1 + l_{1} + l_{2} + \cdots \in H^{*}(BSG, \mathbb{Z}/8)$. In §8, $l$ is defined in terms of a homomorphism on the $\mathbb{Z}/8$ bordism of $MSG$, $\phi: \Omega^{*}(MSG, \mathbb{Z}/8) \to \mathbb{Z}/8$. If $f: M \to MSG$ is a transversal map, $M$ a $\mathbb{Z}/8$ manifold, with $L = f^{-1}(BSG) \subset M$ the associated $\mathbb{Z}/8$ PD space, then

$$\phi[M, f] = \text{index}(L) - 4\langle VSq^{*}(V(M)) \cdot f^{*} \Phi(\mathcal{L}), [M] \rangle \in \mathbb{Z}/8.$$ 

Using results of the Appendix, we show that $\phi$ determines a class $l \in H^{*}(BSG, \mathbb{Z}/8)$ with

$$\phi[M, f] = \langle L(M) \cdot f^{*} \Phi(l), [M] \rangle \in \mathbb{Z}/8.$$ 

**Remark.** Not all elements of $\Omega_{4k}(MSG, \mathbb{Z}/8)$ are represented by transversal maps $f: M \to MSG$. In fact, the subgroup generated by transversal maps has index 2, in each dimension $4k$. To extend the above definition of $\phi$ to all of $\Omega_{4k}(MSG, \mathbb{Z}/8)$, we need to choose a very specific non-transversal element $[K, \alpha]$, set $\phi[K, \alpha] = 0$, and then prove that this is consistent with the definition of $\phi$ on transversal elements.

The class $l$ has the following properties

**Theorem I.** (i) If $L$ is a $\mathbb{Z}/8$ PD space and $\nu: L \to BSG$ is its normal fibration, then

$$\langle \nu^{*}(l), [L] \rangle = \text{index}(L) \in \mathbb{Z}/8.$$ 

(ii) The $\mathbb{Z}/2$ reduction of $l$ is $V^{2} \in H^{*}(BSG, \mathbb{Z}/2)$.

(iii) The class $l$ satisfies the Whitney sum formula

$$\nu(\xi \times \eta) = \nu(\xi) \otimes \nu(\eta) + i(VSq^{*}(V(\xi)) \otimes \mathcal{L}(\eta) + \mathcal{L}(\xi) \otimes VSq^{*}(\eta)) \in H^{*}(B\xi \times B\eta, \mathbb{Z}/8)$$

where $i: H^{*}(\mathbb{Z}/2) \to H^{*}(\mathbb{Z}/8)$ is the natural coefficient map.

(iv) $\beta l = \mathcal{L} \in H^{*+1}(BSG, \mathbb{Z}_{(2)})$, where $\beta$ is the Bockstein homomorphism of the coefficient sequence $0 \to \mathbb{Z}_{(2)} \to \mathbb{Z}_{(8)} \to \mathbb{Z}/8 \to 0$.

Property (iv) relates the $\mathbb{Z}/8$ index class $l$ and transversality obstruction $\mathcal{L}$, and was discussed earlier. Here is a more precise statement of the relation between transversality and the index (mod 8). Suppose $f = M^{q+i+1} \to T^{\xi^{q}}$ is a $\mathbb{Z}/n$ manifold such that $f|_{\delta M}: \delta M \to T^{\xi^{q}}$ is globally transversal. Let $L^{\xi} = f^{-1}(\mathcal{L}^{\xi^{q}}) \cap \delta M$, a closed PD space. If $f: M \to T^{\xi^{q}}$ is itself transversal then index index $(L^{\xi}) = 0$, since
then \( n \cdot L^i \) bounds a PD space, namely \( f^{-1}(\mathcal{M}_\xi) \subset M \). Thus index \((L)\) is an obstruction to cobording the map \( f: M \to T\xi \) to a transversal map. We prove, in fact, that the transversality obstruction \( s_n[M, f] \in \mathbb{Z}/n \) of \( \S 3 \) always has order dividing 8, and is exactly index \((L) \in \mathbb{Z}/8\). (In particular, if \( n \) is odd, \( s_n \equiv 0 \).)

Theorem I(iii), the Whitney sum formula for \( l \), is quite difficult. Its proof requires all of \( \S 9 \), the longest section of the paper. The term which measures deviation from multiplicativity, \( i(VS^qV(\xi) \otimes \mathcal{F}(\eta) + \mathcal{F}(\xi) \otimes VS^qV(\eta)) \), arises for the following reason. If we form a product of transversal maps \( f \) and \( g \), \( f \times g: M^{p+a} \times N^{q+b} \to T\xi \wedge T\eta \), with \( a \) and \( b \) odd, \( a + b \equiv 0(\text{mod } 4) \), then clearly the index of the inverse image of \( B\xi \times B\eta \) is zero, since this inverse is a product of odd dimensional PD spaces. However, if \( f \) or \( g \) is not transversal, it can occur that \( f \times g \) is transversal with nonzero index for the inverse image of \( B\xi \times B\eta \). This implies that, in \( BSG \times BSG \), the \( l \) class can evaluate nontrivially on products of odd dimensional manifolds.

Since \( \mathcal{F} = \beta l \), the Whitney sum formula for \( l \) implies a Whitney sum formula for \( \mathcal{F} \). We also establish in the paper a Whitney sum formula for the class \( \mathcal{F} \), namely

**Theorem J.**

\[
\mathcal{F}(\xi \times \eta) = \mathcal{F}(\xi) \otimes V^i(\eta) + V^i(\xi) \otimes \mathcal{F}(\eta) \in H^{i-1}(B\xi \times B\eta, \mathbb{Z}/2) .
\]

Using this formula and the fact that

\[
\sigma(\mathcal{F}) = \pi^*(\mathcal{F}) \in H^{i-1}(SG, \mathbb{Z}/2) , \quad \pi: SG \longrightarrow G/TOP ,
\]

(see Theorem H). We deduce

**Corollary K.** \( \mathcal{F} = V^2 \cdot \varepsilon \), where \( \varepsilon = \sum_{i \geq 1} e_{2i-1} \), and \( e_{2i-1} \in H^{2i-1}(BSG, \mathbb{Z}/2) \) is the unique primitive element with

\[
\sigma(e_{2i-1}) = \pi^*(\mathcal{F}_{2i-2}) \in H^{2i-2}(SG, \mathbb{Z}/2) .
\]

Clearly \( \mathcal{F}(\xi) \equiv 0 \) if and only if \( \varepsilon(\xi) \equiv 0 \). Thus, although \( \mathcal{F} \) is nonzero in every dimension \( 4i - 1 \), \( i \geq 1 \), the “marrow” of the \( \mathcal{F} \)-class is concentrated in dimensions \( 2^i - 1 \). There is evidence that this class \( \varepsilon \) is the same as the class defined by D. Ravenal in terms of twisted secondary operations [21]. \( \varepsilon \) is definitely equal to the class in dimensions \( 4^* - 1 \) produced by Madsen and Milgram’s result that \( B(G/TOP)_{(4)} \equiv \prod_{i \geq 1} K(\mathbb{Z}/2, 4i - 1) \times K(\mathbb{Z}/2, 4i + 1) \).

Chapter IV, which consists of \( \S \S 10 \) and 11, is concerned with
giving homotopy theoretic definitions of the classes $\Xi$ and $\hat{\Omega}$. Section 10 extends slightly recent work of W. Browder, [1]. Namely, Browder observed that if a sphere $\alpha: S^{q+i-1} \to T(\xi)$ is transversal, then $\alpha$ lifts to $\tilde{\alpha}: S^{q+i-1} \to T(\xi^g\langle v_{2i}\rangle)$, where $K(Z/2, 2i - 1) \to B\xi^g\langle v_{2i}\rangle \to B\xi^g$ is the fibration which kills the Wu class $v_{2i}(\xi) \in H^{2i}(B\xi^g, Z/2)$, and $\xi^g\langle v_{2i}\rangle$ is the bundle $\xi^g$ lifted to $B\xi^g\langle v_{2i}\rangle$. $\alpha$ lifts to $\tilde{\alpha}$ because if $K^{4i-1}$ is a PD space of dimension $4i - 1$, $v_{2i}(K^{4i-1}) = 0$. Browder then proved that the homomorphism

$$\rho_*: \pi_{q+4i-1}(T\xi) \to \pi_{q+4i-1}(T\xi^g/T(\xi^g\langle v_{2i}\rangle))$$

has image $(\rho_*) \subset Z/2$ and that $\rho_*(\alpha)$ agrees exactly with the Levitt obstruction to transversality on spheres $\alpha: S^{q+i-1} \to T(\xi)$. Moreover he showed how $\rho_*(\alpha) \in Z/2$ is computed as an explicit functional cohomology operation.

We observe that since $\tilde{\Omega}_q(T\xi, Z/2) \cong \pi_q(T\xi \land MO \land RP(2))$, we can use Browder’s functional operation on homotopy elements in the Thom space $T\xi \land MO \land RP(2)$ to compute $s_\xi: \Omega_{q+4i-1}(T\xi^g, Z/2) \to Z/2$. Since $s_\xi$ defines $\hat{\Omega}(\xi)$, we obtain an alternate definition of $\hat{\Omega}(\xi)$, purely in terms of homotopy theoretical constructions. We use this functional operation definition, in fact, to prove the Whitney sum formula of Theorem J for the class $\hat{\Omega}$.

In §11, we give a somewhat similar homotopy theoretic definition of the $Z/8$ index homomorphism $\Omega_{q+4}(T\xi^g) \to Z/8$ (see Theorem B and Lemma C). Since this determines the transversality obstruction homomorphisms $s_\xi: \Omega_{q+4i+1}(T\xi^g, Z/n) \to Z/n$, (see the discussion of Theorem I(iv)), we obtain a homotopy theoretical definition of the class $\hat{\Omega}(\xi)$.

The paper concludes with an Appendix describing how to define $Z/2$, $Q$, $Z_{(i)}$, or $Z/2^r$ cohomology classes of a space $X$, in terms of homomorphisms on the bordism of $X$ with various coefficients. The cases $Z/2$, $Q$, and $Z_{(i)}$ are discussed thoroughly in [23] and [15]; the $Z/2^r$ case is implicit in [15] and [13]. We include the Appendix primarily for completeness.

**Chapter I**

1. **The obstruction theory.** In this section we will set up an obstruction theory for the question of putting a manifold fiber homotopy transverse regular to the base of a spherical fiber space. This obstruction theory is just a recasting of the one originally developed in [10] except that we make different technical assumptions about the class of maps which we will consider. This allows us to avoid the difficulties encountered in the original theory. We will prove that if $f: D^{s+k} \to T(\xi^g)$ is f.h.t. on the boundary and $\xi^g$ admits a PL
structure (though none is preferred) then there is one obstruction \( \alpha \in P_{k-1} \) to shifting \( f \) relative to the boundary to a transversal map. \( \alpha \) is the surgery obstruction of the following normal map. Put a PL structure on \( \xi^q \) and shift \( f \) slightly to be PL transverse. Let \( Y^q = f^{-1}(0\text{-section}) \). Then \( \partial Y^q \subset f^{-1}(M_i) \cap S^{q+k-1} \) is a degree one normal map. We show that \( \alpha \) is well defined independent of the PL structure we put an \( \xi^q \).

Using this local result we are able to develop an obstruction theory. Namely, let \( f : M^{q+k} \rightarrow T(\xi^q) \). Suppose we are given a triangulation of \( M \) such \( f \) (any simplex) is contained in the Thom space of a bundle admitting a PL structure. Then we have an obstruction theory to inductively deforming \( f \) over the skeleta of \( M \) to be f.h.t. The obstructions lie in \( H^*(M; P_*; \mathbb{Z}) \). The rest of this paper involves ramifications of this theory.

We begin by recalling the definition of fiber homotopy transverse regular (denoted f.h.t.). Let \( E(\xi^q) \rightarrow X \) be a spherical fiber space (i.e., the homotopy theoretic fiber of \( \pi \) is \( S^{q-1} \)). Let \( M_i \) be the mapping cylinder of \( \pi \) and let

\[
T(\xi^q) = M_i \cup_{E(\xi^q)} \text{cone}(E(\xi^q)).
\]

\( T(\xi^q) \) is the Thom space of \( \xi^q \). \( E(\xi^q) \subset T(\xi^q) \) has a trivial line bundle as normal bundle

**DEFINITION 1.1.** \( f : M^{q+n} \rightarrow T(\xi^q) \), \( M \) a closed PL manifold, is globally fiber homotopy transverse to \( X \), (f.h.t.) if and only if

(1) \( f \) is PL transverse to \( E(\xi^q) \subset T(\xi^q) \) and

(2)

\[
\begin{array}{ccc}
E(\xi^q) & \rightarrow & E(\xi^q) \\
\downarrow & & \downarrow \\
M_i & \rightarrow & M_i
\end{array}
\]

is a map of spherical fiber spaces. Of course, the spherical fibration on the right is canonically equivalent to \( E(\xi^q) \rightarrow X \).

From this definition it follows easily that \( f^{-1}(M_i) \) is a Poincaré duality space, (PD space) of formal dimension \( n \) (see [24] for a definition), and that its normal bundle in \( M^{q+n} \) is induced from \( \xi \) by \( f \) restricted to \( f^{-1}(M_i) \).

If \( M^{q+n} \) is a manifold with boundary, we require
to be maps of spherical fiber spaces. It follows in this case that
\((f^{-1}(M_t), f^{-1}(M_t) \cap \partial M)\) is a Poincaré duality pair (PD pair), of formal
dimension \(n\).

We will use a stronger, local concept of transversality.

**Definition 1.2.** Let \(M^{q+n}\) be a PL manifold with a given combina-
torial triangulation, and let \(\xi\) be as before. We say that \(f:\ M^{q+n} \to T(\xi)\) is strongly f.h.t. if and only if
\[
\begin{align*}
(1) & \quad f|_{\Delta^i}: \Delta^i \to T(\xi) \text{ is f.h.t. for each simplex } \Delta^i \text{ in the triangula-
tion of } M, \text{ and} \\
(2) & \quad (f^{-1}(M_t) \cap \Delta^{q+2}, f^{-1}(M_t) \cap \partial \Delta^{q+2}) \text{ is then a 2 dimensional PD pair;} \text{ we require that this pair be homotopy equiva-
ient to a PL 2-manifold with boundary.}
\end{align*}
\]

This definition requires some explanation. First, there is a great
difference between a map of a manifold into a spherical fibration
being f.h.t. and strongly fiber homotopy transverse, even if we ignore
the extra low dimensional condition. We will see later that the
former is analogous to requiring a map between simply connected
manifolds to have 0 surgery obstruction (i.e., be normal cobordant
to a homotopy equivalence), whereas the latter is analogous to requiring
all the splitting invariants of the map to be 0. (Which of course
makes it normally cobordant to a homeomorphism.) The analogy is
easily understood from the remark that if \(f; M^q \to T(\xi)\) is strongly
transverse then so is \(f\) restricted to any simplicial singular subman-
ifold of \(N\) (i.e., \(N \xrightarrow{r} M \xrightarrow{f} T(\xi)\) for \(N\) a manifold and \(r\) simplici-
cal). Secondly, the condition on the \((q+2)\)-simplicies is to circum-
vert our lack of understanding of G-framed PD bordism in dimension 2.
We will reduce problems about f.h.t. on \((q+k)\)-simplicies to problems
about G-framed PD bordism in dimension \(k\). We will be able to
handle the problems about G-framed PD bordism except in dimension
2 where we will use the extra hypothesis.

The main theorem of this section is the following.

**Theorem 1.3.** If \(\xi^q \xrightarrow{\pi} X\) is a spherical fibration, \(\pi_1(X) = 0\),
\(q \geq 3\), \(\xi^q\) admits a block PL structure, and
\[
f: D^{q+n+1} \to T(\xi^q) \text{ is f.h.t. on } S^{q+n},
\]
then
(1) if \( n \neq 2 \) there is well-defined element in \( P_n \) (the \( n \)th surgery obstruction group) whose vanishing is necessary and sufficient for \( f \) to be homotopic relative to \( S^{q+n} \) to a f.h.t map.

(2) If \( n = 2 \) the above conclusion holds if in addition \( f^{-1}(M_i) \cap S^{q+n} \) is homotopy equivalent to a 2-manifold.

(3) If \( h_i \) is a homotopy relative to \( S^{q+n} \) from \( f \) to a f.h.t. map we may assume \( h_i^{-1}(M_i \cup E(\xi^q) \times [0, 1/2]) \) is constant. (Here \( E(\xi^q) \times [0, 1/2] \subset E(\xi^q) \times [0, 1]/(E(\xi^q) \times [1]) = \text{cone}(E(\xi^q)). \)

We emphasize that we do not have a PL structure for \( \xi^q \), only the hypothesis that one exists.

**Proof.** We first need a lemma from the theory of PD spaces to the effect that 1-dimensional surgery is possible.

**Lemma.** Let \( M^{q+n} \xrightarrow{f} T(\xi^q) \) with \( 3 \leq n, 3 \leq q, \pi_1(M) = 0 \) and \( \pi_i(X) = 0 \). Assume also that \( f \) is f.h.t. Then there is a homotopy \( F: M \times I \to T(\xi^q), F|_{M \times [0]} = f \) which is f.h.t. with \( F^{-1}(M_i) \cap M \times [1] \) simply connected.

For a proof when \( n \geq 4 \) see [10]. For \( n = 3 \) use the fact [24] that any 3 dimensional PD space is bordant to \( S^3 \). (In fact this bordism can be taken to be framed.)

We now return to a proof of the theorem. Put a block PL structure on \( \xi^q, E^q \to \xi^q \). In this structure shift \( f \) slightly to \( f' \) which is block PL transversal to a small block tube around the 0-section of \( E \). We clearly may do this so that \( f^{-1}(M_i) \cap S^{q+n} \) and \( f^{-1}(M_i \cup E(\xi) \times [0, 1/2]) \) do not change. That is to shift a map to a PL transversal one we need only alter it in a neighborhood of the 0-section. Let \( Y^{n+1} = f^{-1}(0 \text{-section}) \) and \( Z = f^{-1}(M_i) \). \( Y^{n+1} \) is a PL manifold of dimension \( n + 1 \) with boundary equal to \( Y \cap S^{q+n} = W^s \). \( Z \cap S^{q+n} \) is an \( n \)-dimensional PD space, and \( W^s \subset Z \cap S^{q+n} \). We claim that \( W^s \subset Z \cap S^{q+n} \) naturally has the structure of a degree one normal map. This is proved by the following lemma.

**Lemma 1.4.** Let \( f: M^{q+n} \to T(\xi^q) \) be f.h.t. with \( f^{-1}(M_i) = X \). Suppose \( \xi^q \) has a PL structure, \( E \), and \( h_i \) is a homotopy from \( f \) to a block PL transversal map \( f': M \to T(\xi^q) \) with the property that \( h_i^{-1}(M_i) \) is constant. Let \( f'^{-1}(0) = Y \).

Then \( Y \subset X \) is a degree one map and is naturally covered by a bundle map.
Proof. \( Y \subset X \) since \( Y = h_i^{-1}(0\text{-section}) \subset h_i^{-1}(M_i) = h_0^{-1}(M) = X \). \( X = f^{-1}(M_i) \) is a codimension 0-submanifold of \( M^{q+n} \) and the fundamental class, \( [X] \in H_n(X) \) is \( f^* U_\xi \cap [X, \partial X] \) where \( U_\xi \) is the Thom class of \( \xi \). \( i_*[Y] \in H_n(X) = h^*_\xi U_\xi \cap [X, \partial X] \). Since \( h_1 \equiv f \) we see that \( i_*[Y] = [X] \) in \( H_n(X) \). Thus \( Y \subset X \) is degree +1

\[
\nu_Y \longrightarrow f^* E \oplus \nu_M|_X \\
\downarrow \quad \downarrow \\
Y \longrightarrow X
\]

Thus we have a natural bundle map

\[
\nu_{Y \subset M} \cong \nu_{Y \subset M} \oplus \nu_M|_Y .
\]

\[
\nu_{Y \subset M} = i^* h_1^* E \cong i^* h_0^* E = i^* f^* E .
\]

This induces

\[
\nu_Y = \nu_{Y \subset M} \oplus \nu_M|_Y \xrightarrow{\alpha} f^* E \oplus \nu_M|_X \\
\downarrow \quad \downarrow \\
Y \longrightarrow X
\]

which is the bundle map covering \( i \). This proves the lemma. Applying this to the situation in Theorem 1.3 we see that \( W = Y \cap S^{q+n} \longrightarrow Z \cap S^{q+n} \) is a degree one normal map. Thus there is naturally associated an element in \( \tilde{P} \) (the surgery obstruction of this normal map). We call this element \( \sigma(f) \). We must show that:

1. \( \sigma(f) \) is well defined depending only on the homotopy class of \( f \) (the homotopy required to be f.h.t. on \( S^{q+n} \times I \)) and

2. if \( \sigma(f) = 0 \), then we may put \( f \) f.h.t. relative to \( f|S^{q+n} \) keeping the preimage of \( M_{i} \cup E(\xi) \times [0, 1/2] \) constant.

We consider the second question first.

Case \( n \geq 5 \). By the first lemma we may assume that

\[
\pi_1(Z \cap S^{q+n}) = 0 .
\]

Thus if the surgery obstruction vanishes, we may do surgery until \( W \rightarrow Z \cap S^{q+n} \) is a homotopy equivalence. These surgeries are realized by shifting \( f' \) slightly but may be done so as not to change the preimage of \( M_i \) or \( M_i \cup E(\xi) \times [0, 1/2] \). Here we are using the fact
that surgery is possible in codimension 3. Thus we may assume that
in addition to all the above conditions that $W \subset Z \cap S^{q+n}$ is a homotopy
equivalence. Thus $(Z \cap S^{q+n}) \cup$ (tubular neighborhood of $Y$) is a PD
space in $M$. It is the f.h.t. preimage of a map $f': D^{q+n+1} \to T(\xi^q)$. In
constructing this map $f'$ we have shifted $f$ on the boundary $S^{q+n}$,
but we have not moved $f^{-1}(M_\xi \cap S^{q+n})$ during the homotopy. Thus
the standard collaring trick allows us to work relative to $S^{q+n}$. This
verifies the second condition for $n \geq 5$. For $n < 5$ we use the same
general argument but we must show that we can do the requisite surgery.

Case $n = 4$. Here again we may assume that $Z \cap S^{q+n}$ is simply
connected. Use the fact that in dimension 4 surgery is possible
after sharpening enough times with $S^2 \times S^2$ see for example [24]. It
is always possible to add to $Z \cap S^{q+4}$ a copy of $S^2 \times S^2$ by performing
a f.h.t. homotopy. Thus if the surgery obstruction vanishes we may
make $W \subset Z \cap S^{q+4}$ a homotopy equivalence.

Case $n = 3$. Here we may assume $Z \cap S^{q+2}$ is homotopy equivalent
to $S^3$. Then we use the fact that any surgery problem with domain
a PL manifold and range $S^3$ may be solved.

Case $n = 2$. Here we must use the extra hypothesis that $Z \cap S^{q+2}$
is homotopy equivalent to a 2-manifold, and the fact that for surgery
problems between 2 manifolds surgery is possible (after a bordism
of the range) if and only if the Kervaire obstruction vanishes.

Cases $n \leq 1$ are trivial.

Using all these special tricks in low dimensions one then pushes
the high dimensional argument through. The details are left to the
reader.

We now turn to the question of the well-definedness of the obstruc-
tion $\sigma(f)$. We will use the following standard fact from surgery
theory.

(* ) If $f: L^{n+1} \to R^{n+1}$ is a normal map between PD space then
$\sigma(f|\partial L)$ is 0 in $P_n$. See [2]. Suppose that $F: D^{q+n+1} \times I \to T(\xi^q)$ is
f.h.t. when restricted to $S^{q+n} \times I$. Let $F^{-1}(M_\xi) \cap S^{q+n} \times I = X$ and
$X \cap S^{q+n} \times [i] = X_i, i = 0$ or 1. Suppose that in $D^{q+n+1} \times [1]$ we have
a PD pair $(R^{n+1}, \partial)$ obtained as follows. Let $M'_\xi \subset M_\xi$ be a smaller
copy of the mapping cylinder. We shift $F|D \times [1]$ to $G$ which is
f.h.t. with respect to $M'_\xi$ in such a way that $G^{-1}(M'_\xi) = f^{-1}(M_\xi) \cap
D^{q+n+1} \times [1]$. Then $\partial R \subset X_i$ is a degree one normal map between
PD spaces. (As an example, $R$ could be the tubular neighborhood
of the preimage of the 0-section under some map PL transverse in
a different PL structure on $\xi^q$.) Since the homotopy from $F$ to $G$ on $D \times [1]$ left the preimage of $M_i$ constant, we may assume that $F|D \times [1] = G$.

Now put a PL structure on $\xi$ and shift $F$ slightly to $F''$ which is block PL transverse. Do this keeping $F''(M_i)$ and $F''(M_i')$ constant.

Let $A = F''(0)$, and $A_i = A \cap D \times [i]$. We wish to show that the surgery obstruction of $\partial A_i \to X_0$ equals that of $\partial R \to X_i$. This will then prove the well definedness of $\sigma(f)$. Since $A_i \to R$ is a degree one normal map, (*) implies that $\sigma(\partial A_i \to \partial R)$ is 0. Also $\sigma(\partial A_0 \to X_0) = \sigma(\partial A_i \to X_i)$ since $\partial A \to X$ is a degree one normal map. $\partial A_i \to X_0$ is the composite of two surgery problems $\partial A_i \to R \to \partial R \to X_i$. Thus $\sigma(n_2 \circ n_i) = \sigma(\partial A_i \to X_i)$ and $\sigma(n_i) = 0$. If we knew that $\sigma(n_2 \circ n_i) = \sigma(n_2) + \sigma(n_i)$ it would follow that $\sigma(n_2) = \sigma(\partial A_0 \to X)$ which is what we wish to prove.

In the signature case such an additivity formula is obvious. In the Kervaire invariant case it is not true in general that $\sigma(n_2 \circ n_i) = \sigma(n_2) + \sigma(n_i)$. We need additional information.

In this case we may do surgery on $\partial A_i \to \partial R$ until it is a homotopy equivalence. (In the low dimensions first cross with $\mathbb{CP}^2$.) After doing this the crucial point is that the bundle map covering $\partial A_i \to \partial R$ is $n_i : \nu_\partial A_i \to \nu_\partial R$, or equivalently if we use the homotopy equivalence $n_i$ to identify $\partial A_i$ with $\partial R$ then the bundle maps given by $n_2 \circ n_i$ and $n_2$ are the same. This is clear since $F''$ is homotopic to $F'$ as maps of spherical fiber spaces

$$F' : \nu_{\partial R} \longrightarrow \nu_{\pi} \quad \text{and} \quad F : \nu_{\partial A_1} \longrightarrow \nu_{\pi}.$$

This proves the well definedness of $\sigma(f)$ and completes the proof of Theorem 1.3. Once we have this theorem the obstruction theory now follows by the usual formal type arguments. Setting it up is the aim of the rest of this section.

Statement of the obstruction theory. Let $\xi^q \to X$ be a spherical fiber space. Suppose we are given an open cover $\{U_a\}$ of $X$ such that the base point of $X, *$, is in each $U_{a_1} \cap \cdots \cap U_{a_k}$ is connected and simply connected for all $[a_1, \cdots, a_k]$, and such that $\xi | U_{a_k}$ admits a PL structure. Form the open cover $\{V_a\}$ of $T(\xi^q)$ where $V_a = M_i | U_a \cup$ open cone $(E(\xi))$. Let $M$ be a triangulated PL manifold, and suppose $f : M^{q+n} \to T(\xi^q)$ has the property that $f(\partial A^i)$ is contained in some $V_a$ for each $A^i$ in the triangulation of $M$, (i.e., $f$ is small with respect to the cover $\{V_a\}$). Then there is an Eilenberg-MacLane obstruction theory for deforming $f$ inductively over the skeleta of $M$ until it is strongly f.h.t. such that if $f(\partial A^i) \subset V_a$ then $A^i$ stays in $V_a$ during the deformation.
NOTE. The conditions that all $U$ contain $\ast$ and that all intersections are connected and simply connected implies that $\pi_1(X) = 0$ by Van Kampen's theorem. The converse is proved in next lemma.

**Lemma 1.5.** Any simply connected complex $X$ has a covering $\{U_a\}$ satisfying all the above properties and such that for any spherical fibration $\xi^q \to X$, $\xi|U_a$ admits a PL structure for each $U_a$ in the cover.

**Proof.** Let $X$ be a simplicial complex. For each vertex $\alpha$ of $X$, let $U_\alpha$ be the open star in the second derived subdivision of the closed set $(X^{(2)} \cup \text{closed } st(\alpha))$. Then any intersection $U_{\alpha_1} \cap \cdots \cap U_{\alpha_n}$ deforms to the two skeleton of $X$ which is connected and simply connected if $X$ is. Also $\xi|U_\alpha$ admits a PL structure since any spherical fiber space over a 2 complex does.

**Definition.** We call covers satisfying all the above properties good covers. Note that each simplex of $X$ is in one of the open sets of the cover. We will need this later in the paper.

**Note.** The cover that we constructed in the above lemma is natural with respect to simplicial maps $F: X \to Y$. The condition that a map be small with respect to an open cover can always be realized by subdivision. However, it is not clear that if a map is strongly f.h.t. that the domain can be subdivided and the map shifted until it is strongly f.h.t. and small with respect to the cover. Philosophically, this smallness condition is related to the fact that PL transversality can be accomplished by an arbitrarily small shift.

To set up the obstruction theory we need some corollaries of Theorem 1.3. Let $\pi_{q+n+1}(T(\xi^q), \text{s.f.h.t.})$ be, as a set, the set of homotopy classes of maps $D^{n+1} \overset{f}{\to} T(\xi^q)$ such that $f$ is f.h.t. on $\partial D^{n+1}$ and in addition if $n = 2$, then $f^{-1}(M_\xi)$ is homotopy equivalent to a 2-manifold. The group structure is given by connected sum along the boundary where we sum small disks which go to the cone point.

**Corollary 1.6.** If $\xi^q \to X$ is a spherical fiber space with $X$ connected and simply connected and such that $\xi^q$ admits a PL structure then we have an isomorphism

$$\pi_{q+n+1}(T(\xi^q), \text{s.f.h.t.}) \xrightarrow{\cong} P_n$$

for $q \geq 3$.

**Proof.** Theorem 1.3 sets up a well defined function

$$\pi_{q+n+1}(T(\xi^q), \text{s.f.h.t.}) \xrightarrow{\tau} P_n$$
which is easily seen to be a group homomorphism. If \( \tau(f) = 0 \), then \( f \) is homotopic relative to \( \partial D \) to a f.h.t. map. This, of course means \( [f] = 0 \in \pi_{q+i+1}(T(\xi^q)) \), s.f.h.t.). Thus \( \tau \) is 1-1. To show that \( \tau \) is onto let \( \alpha \in P_* \). Then there is a \( G \)-framed PD space

\[
\begin{array}{ccc}
\nu^\alpha_X & f & \xi^q \\
\downarrow & & \downarrow \\
X^* & \longrightarrow & * \\
\end{array}
\]

such that if we make \( f \) PL transverse regular to \( 0 \in \xi^q \), say \( f^{-1}(0) = Y^* \), then \( \sigma(Y^* \to X^*) = \alpha \). Furthermore, \( \phi: S^{q+n} \to T(\nu^\alpha) \to S^q \) is homotopic to 0. See [10]. Define \( f: D^{q+i+1} \to T(\xi^q) \) to be a homotopy from \( \phi \) to *. One sees easily that \( D^{q+i+1} \to T(\xi^q) \subseteq T(\xi^q) \) is a map with obstruction \( \alpha \). This proves \( \tau \) is onto.

**Definition of the obstruction cochain.** Let \( f: M^{q+n} \to T(\xi^q) \) be small with respect to the good cover as in 1.5, \( \{V_\lambda\} \), and suppose \( f\mid(q+i-1)\)-skeleton is s.f.h.t.. Let \( \Delta^{q+i} \) be a \((q+i)\)-simplex in \( M^{q+n} \). There is at least one of the open sets \( U_\rho \) of \( X \) for which \( f\mid \Delta^{q+i}: \Delta^{q+i} \to T(\xi|U_\rho) \cup C(\xi) \) and \( f\mid \partial \Delta \) is s.f.h.t. Since \( U_\rho \) is connected and simply connected and \( \xi|U_\rho \) admits a PL structure, we assign to \( \Delta^{q+i} \), \( \sigma(f\mid \Delta^{q+i} \to T(\xi|U_\rho)) \). We must show that \( \sigma \) is independent of \( U_\rho \), i.e., if \( f\mid \Delta^{q+i} \) is also contained in \( U'_\rho \), then \( \sigma(f\mid \Delta^{q+i} \to T(\xi|U'_\rho)) = \sigma(f\mid \Delta^{q+i} \to T(\xi|U_\rho)) \). This follows easily from Lemma 1.4. This gives us a well defined cochain \( o(f) \in \text{Hom}(C_{q+i}(M), P_{-i}) \).

\( o(f) \) is a cocycle. To see this we must show that \( \langle o(f), \partial \Delta^{q+i+1} \rangle = 0 \). We have \( f: \Delta^{q+i+1} \to T(\xi|U_\rho) \) and \( \xi|U_\rho \) admits a PL structure. In \( \partial \Delta^{q+i+1} = S^{q+i} \) take a collar neighborhood of the \((q+i-1)\)-skeleton, \( C \). We may easily shift \( f \) to be f.h.t. on this neighborhood. \( \partial C \) has one component equal to \( S^{q+i-1} \) for each \((q+i)\)-simplex of \( \partial \Delta^{q+i+1} \).

Shift all of \( C \) PL transverse to some PL structure on \( \xi|U_\rho \). Let \( Y = \) the preimage of the 0-section then \( Y \subseteq f^{-1}(M_\xi) \cap C \) is a degree one normal map. Thus \( \sigma(Y \cap \partial C \subseteq f^{-1}(M_\xi) \cap \partial C) = 0 \). On the other hand one sees that this latter surgery obstruction is \( \sum_{j=0}^{q-i-1} (-1)^j o(j\text{th face}) \). Where \( o(j\text{th face}) \) means \( \langle o(f), j\text{th face of } \Delta^{q+i} \rangle \). Thus \( \langle o(f), \partial \Delta^{q+i+1} \rangle = 0 \).

If \( o(f) = 0 \) as a cochain we may shift \( f \) relative to the \((q+i-1)\) skeleton of \( M \) to \( f \), which is f.h.t. on the \((q+i)\) skeleton. Furthermore, we can do this in such a way as to keep \( \Delta^q \) in \( V_\rho \) whenever \( f(\Delta^q) \subset V_\rho \).

**Proof.** We work one \((q+i)\)-simplex at a time. Since \( f(\Delta^q) \subset V_\rho \).
We have all the hypothesis to apply Theorem 1.3. The result follows easily from it. Note that we may do this keeping the preimage of $M_i \cup E \times [0, 1/2]$ constant by Property 3 of 1.3.

By shifting $f$ on the $(q + i - 1)$ skeleton by a homotopy (but not a transversal homotopy) relative to the $(q + i - 2)$-skeleton we may change $o(f)$ by an arbitrary coboundary.

**Proof.** Here we will use the fact that the base point is in all of the $U_\rho$'s, and thus $T(\varepsilon) \subset V_\rho$ for every $\rho$. We will change $o(f)$ by $\delta e_{i-1}$ where $\langle e_{i-1}, A_i^{q+i-1} \rangle = \alpha \in P_{i-1}$ and $\langle e_{i-1}, A_i^{q+i-1} \rangle = 0$ for all other $A_i^{q+i-1}$. Given $\alpha \in P_{i-1}$ we know there is a map $S^{q+i-1} \xrightarrow{\alpha} T(\varepsilon)$ which is homotopic to 0, and which is transversal on $S^{q+i-1}$ obstruction $\alpha$ to extending the transversality on $D^{q+i}$. Pick a disk a disk $D^{q+i-1}_0 \subset A^{q+i-1}_i$ missing $f(M_i)$ and change $f$ by a homotopy on this disk relative to its boundary until on the interior of $D^{q+i-1}_0$ it agrees with $\alpha$. Then use homotopy extension to extend this to all of $M^{q+n}$. One checks easily that this changes $o(f)$ exactly by $\delta e_{i-1}$. This completes the proof of the obstruction theory.

**Note.** There is one condition that we must verify and that is in going from the $(q + 1)$-skeleton to the $(q + 2)$-skeleton that all $(f^{-1}(M) \cap A_i^{q+2}), f^{-1}(M_i \cap \partial A^{q+2}_i)$ are homotopy equivalent to PL 2-manifolds with boundary. This, however, is easy to arrange. Then for any $A_i^{q+2}$, $f^{-1}(M_i) \cap \partial A^{q+2}$ will be homotopy equivalent to a 2-manifold.

**Note.** If we wish to change $o(f)$ by $\delta e_{i-1}$ where $\langle e_{i-1}, A_i^{q+i-1} \rangle = 1$ and $\langle e_{i-1}, A_i^{q+i-1} \rangle = 0$ for all other $A_i^{q+i-1}$ we may do this keeping $f^{-1}(M_i \cup E \times [0, 1/2])$ constant providing only that

$$f^{-1}(M_i \cup E \times \left[0, \frac{1}{2}\right]) \cap A_i^{q+i-1}$$

contains a small disk $D^{q+i-1}$. To see this we use the following lemma

**Lemma 1.8.** Given $\alpha \in P_n$, there is a map $g: D^{q+n+1} \to T(\varepsilon)$, which is f.h.t. on $S^{q+n}$ with obstruction $\alpha$ with $g(D^{q+n+1})$ contained in an arbitrarily small neighborhood of $\ast \in T(\varepsilon) = S^n$.

**Proof.** The argument in 1.6 produces $g: D^{q+n+1} \to T(\varepsilon)$ f.h.t. on $S^{q+n}$ with obstruction $\alpha$. Let $0$ be the image of the base of $\varepsilon$ in $T(\varepsilon)$ and 1 the antipodal point on $T(\varepsilon) = S^n$. Leaving $g|S^{q+n}$ fixed near 0 we wish to make it miss 1. Since we have $g: S^{q+n} \to S^n$ the only obstruction to making $g$ miss the point $1 \in S^n$ is the element in
framed bordism $g^{-1}(1)$ after $g$ has been shifted transverse to 1. But since $g$ bounds $D^{q+n+1}$ this element is 0. Thus we make shift $g$ slightly near $1 \in S^q$ to make it miss $1 \in S^q$. Once we have $g|\partial D^{q+n+1}$ missing 1 by changing the map by an element in $\pi_{q+n+1}(S^q)$ we may make $g$ on all of $D^{q+n+1}$ miss 1.

Now if we wish to change $o(f)$ by $\delta e^i$ as above and if $D^{q+i-1} \cap f^{-1}(M \cup E \times [0, 1/2])$ contains a disk $D^{q+i-1}$ we may first assume that this disk is contained in $f^{-1}E \times [0, 1/2]$ and that it maps by $f$ to a point. Now use the previous lemma to shift $f$ near this disk. Since $g(D^{q+n+i}) \subset M \cup E \times [0, 1/2]$ the process never moves any point near $D^{q+i-1}$ outside of $M \cup E \times [0, 1/2]$.

**NOTE.** Since this theory is "one simplex at a time relative to its boundary" there is clearly a relative obstruction theory for deforming a map $f: M^{q+n} \to T(\xi^q)$ relative to a subcomplex $K$ on which it is already strongly f.h.t. The obstructions lie in $H^{q+i}(M, K; P_*).$

Also note that if $L$ is a subcomplex of $M$ which $f$ sends to the cone point, then, after $f$ is shifted to $f'$ which is strongly f.h.t., $f'$ maps $L$ into $T(\xi^q|U)$ where $U$ is an arbitrary contractable open set containing the base point.

**NOTE.** The obstruction theory is natural with respect to simplicial maps of bases covered by bundle maps, i.e.,

$$
\begin{array}{cc}
\xi^q & \longrightarrow & T^q \\
\downarrow & & \downarrow \\
X & \xrightarrow{f} & Y
\end{array}
$$

where $f$ is simplicial. The fact that $f$ is simplicial implies that it respects the chosen covers on $Y$ and $X$. From this naturality follows easily. The obstruction theory is also natural with respect to suspensions.

Namely given $f: M^{q+n} \to T(\xi^q)$ small with respect to the cover we may suspend to form $M \times I \xrightarrow{\sum f} T(\xi^q \oplus e')$ where $\sum f| M \times \hat{I}$ is the point map. The obstructions for $f$ lie in $H^{q+i}(M^{q+n}; P_*)$ and the obstructions for $\sum f$ are in $H^{q+i+1}(M^{q+n} \times I, M^{q+n} \hat{I}; P_*) \cong H^{q+i+1}(\sum M, P_*)$. If we have a deformation of $f$ to be f.h.t. on the $(q+i)$-skeleton, then this gives a deformation of $\sum f$ on the $(q+i+1)$-skeleton of $M \times I$. The obstructions to extending the maps further agree under the suspension isomorphism.

2. First consequences of the obstruction theory. In this section we wish to formulate homotopy theoretic consequences of the obstruct-
tion theory of §1. Let \( \xi^q \to X \) be a spherical fiber space, \( q \geq 3 \), \( \pi_i(X) = 0 \) and \( \{ U_i \} \) be the cover of \( X \) and \( \{ V_\alpha \} \) the associated cover of \( T(\xi^q) \) as in 1.5. (We shall always work with these covers unless otherwise specified.)

**Definition 2.1.** \( W_\xi \) is the semi-simplicial complex of all strongly f.h.t. maps \( \mathcal{A}^i \to T(\xi^q) \) which are small with respect to the cover \( \{ V_\alpha \} \). Denote by \( \overline{T}(\xi^q) \) the total singular complex of \( T(\xi^q) \). Then we have a natural map \( W_\xi \to \overline{T}(\xi^q) \). Let \( F_\xi \) be the homotopy theoretic fiber of this inclusion. The following is a representative semi-simplicial complex for \( F \). The \( i \)-simplices are maps \( h: \Delta^i \times I \to T(\xi^q) \) with \( h|\Delta^i \times \{0\} \) strongly f.h.t. and small with respect to the cover and \( h|\Delta^i \times \{1\}: \Delta^i \times \{1\} \to \text{cone point} \).

We shall construct in this section homomorphisms from bordism groups of this fiber to the surgery obstruction groups. These homomorphism will measure the obstruction to global transversality. We shall show that they satisfy all of the natural compatibility relations and product formulae analogous to those for surgery obstructions. (In fact the homomorphisms are surgery obstructions.) Later in this paper we shall use these homomorphisms and the product formulae that they satisfy to derive further homotopy theoretic consequences. This is the reason that we state them now. First, however, we relate the homotopy groups of \( F_\xi \) to the surgery obstruction group.

**Theorem 2.2.** \( \pi_i(F_\xi) \cong P_{i-q} \) provided that \( q \geq 3 \).

**Proof.** We show that there is a natural \( \pi_i(F_\xi) \to \pi_{i+1}(T(\xi^q), \text{strongly f.h.t.}) \). But by the obstruction theory \( \pi_{i+1}(T(\xi^q), \text{strongly f.h.t.}) \to P_{i-q} \). An element in \( \pi_i(F_\xi) \) is a map \( S^i \times I \to T(\xi^q) \) such that \( h|S^i \times \{0\} \) strongly f.h.t. and \( S^i \times \{0\} \) is triangulated so that \( h \) is small with respect to the cover and \( h(S^i \times \{1\}) = \text{cone point} \). Thus we may factor \( h \) through \( S^i \times I/S^i \times \{0\} = D^{i+1} \). This gives the map \( \pi_i(F_\xi) \to \pi_{i+1}(T(\xi^q), \text{strongly f.h.t.}) \). The proof that it is well defined and the construction of the the inverse are analogous.

**Lemma 2.3.** The PL bordism groups of the geometric realization of \( F_\xi \) are naturally isomorphic to the following groups. As representative elements we take \( H: M^* \times I \to T(\xi^q) \) with \( H|M \times \{0\} \) small with respect to the cover and strongly f.h.t. and \( H|M \times 1: M \times 1 \to \text{cone point} \). Such an element is equivalent to zero if there is an \( \tilde{H}: W^{*+1} \times I \to T(\xi^q) \) with \( \tilde{H}|W \times \{0\} \) small with respect to the cover and strongly f.h.t. and \( \tilde{H}|W \times \{1\} \to \text{cone point} \). And \( \partial W = M \) with
Proof. This follows from the standard arguments in semi-simplicial theory.

Theorem 2.4. There are natural maps

\[ \Omega_{q+i}^{PL}(F_{\xi}) \xrightarrow{\mathcal{O}} P_i \]

\[ \Omega_{q+i}^{PL}(F_{\xi}; Z/n) \xrightarrow{\mathcal{O}_n} P_i \otimes Z/n \]

\[ \gamma_{q+i}^{PL}(F_{\xi}) \xrightarrow{\mathcal{O}} Z/2 \]

satisfying

(i) \( \mathcal{O} \) and the \([\mathcal{O}_n]\) are compatible with the natural maps \( Z \xrightarrow{red} Z/n \) and \( Z/n \xrightarrow{inc} Z/n \cdot k \) in dimensions \( q + 4* + 1 \).

(ii) \( \mathcal{O}, \mathcal{O}_2 \) and \( \widetilde{\mathcal{O}} \) are compatible with the natural maps

\[ \Omega_{q+i-1}(F_{\xi}) \xrightarrow{\mathcal{O}} \Omega_{q+i-1}(F_{\xi}; Z/2) \xrightarrow{\gamma_{q+i-1}(F_{\xi})} \]

(iii) These maps measure the obstruction to global transversality.

(iv) They satisfy the product formulae as in [15] and [22]

(a) \( \eta_*(F_{\xi}) \otimes \eta_*(pt) \xrightarrow{\mathcal{O}} \eta_*(F) \xrightarrow{\mathcal{O}} P_{*-q} \)

sends \((M, f) \otimes N \) to \( \mathcal{O}(M, f) \cdot \chi(N) \)

(b) \( \Omega_{*}^{PL}(F_{\xi}) \otimes \Omega_{*}^{PL}(pt) \xrightarrow{\mathcal{O}} \Omega_{*}^{PL}(F_{\xi}) \xrightarrow{\mathcal{O}} P_{*-q} \)

sends \((M, f) \otimes N^* \) to \( \mathcal{O}(M, f) \cdot I(N) \)

(c) \( \Omega_{*}^{PL}(F_{\xi}; Z/n) \otimes \Omega_{*}^{PL}(pt; Z/n) \xrightarrow{\mathcal{O}} \Omega_{*}^{PL}(F_{\xi}; Z/n) \xrightarrow{\mathcal{O}} P_{*} \otimes Z/n \)

for \( n \) odd sends \((M, f) \otimes N \) to \( \mathcal{O}_n(M, f) \cdot I(N) \) for \( n = 2^k \) the map sends

\[
\begin{cases}
\mathcal{O}(M, f) \cdot I(N) & l \equiv 0(4) \\
2^{k-1} \mathcal{O}_n(M, f) \cdot d(\delta N^1) & m, l \equiv 2(4) \\
2^{k-1} \mathcal{O}(f \mid \delta M) \cdot d(N^1) & m \equiv 3(4) \\
0 & l \equiv 1(4)
\end{cases}
\]

Here \( d(L^{k-1}) \) is the de Rham invariant of skew symmetric linking pairing on a group associated with the homology of \( L \). It is given by the characteristic number \( \langle VSq^1 V, [L] \rangle \in Z/2 \). See [15]. If \( M \) is a \( Z/2^k \)-manifold, \( \delta M \) means the closed codimension one manifold which is the singularity set.

Proof. Construction of the homomorphisms. Let \( M^{q+i} \times I \xrightarrow{H} T(\xi^i) \) with \( H|\partial M \times \{0\} \) strongly f.h.t. and small with respect to \( \{V_\rho\} \), and \( H|\partial M \times \{1\} \) the point map to the cone point. Triangulate \( M \times I \) relative to \( M \times \{0\} \) so that \( H \) is small with respect to \( \{V_\rho\} \). Since \( H^s(M \times I, M \times \{0\}; P_{*-q-1}) = 0 \) we may shift \( H \) relative to \( M \times \{0\} \).
to $H'$ which is strongly f.h.t. Since $H(M \times \{1\}) = \text{cone point}$, $H'(M \times \{1\}) \subset T(\xi \cup U)$ where $U$ is a contractible neighborhood of the base point. Thus $H^{-1}(M_t) \subset M \times \{1\}$ is a PD space with a $G$-framed normal bundle in $M \times \{1\}$. We also have a homotopy of $M \times \{1\} \to T(\nu_{H^{-1}(M_t) \cap M \times \{1\}}) \to T(\xi \cup U)$ to zero. From this we shall read off the obstruction $o$. Let $X^* = H^{-1}(M_t) \cap M \times \{1\}$ and $t: \nu_{X^* M \times \{1\}} \to \mathbb{S}^n$ be the trivialization. Put $t$ PL transversal to $0 \in \mathbb{S}^n$. This gives $Y^* \to X^*$ a degree one normal map. Define $\mathcal{O}(M \times I, H)$ to be the surgery obstruction of this normal map. If $M$ is closed and oriented, then it lies in $P_n$. If $M$ is unoriented, then it lies in $0$ if $n$ is odd and $\mathbb{Z}/2$ if $n$ is even. If $M$ is a closed oriented $\mathbb{Z}/k$-manifold, then it lies in $P_n \otimes \mathbb{Z}/k$. (See [15] §§1 and 5.)

We now prove that $\mathcal{O}$ is well defined depending only on the cobordism class of $(M \times I, H)$. Let $J: W^{q+n+1} \times I \to T(\xi)$ satisfy

(1) $J|W \times \{0\}$ is small with respect to $\{V_\rho\}$ and s.f.h.t.

(2) $J|W \times \{1\}: W \times \{1\} \to \text{cone point}$

(3) $\partial W = M$ and $J|\partial W \times I = H$. (i.e., $(W, J)$ is a bordism of $(H, H)$ to 0 in $F_\xi$.)

Since $H^*(W \times I, W \times \{0\}, P_{*-n-1} = 0$, we may deform $J$ until it is s.f.h.t. on all of $W \times I$, relative to $W \times \{0\}$. This then gives a $G$-framed PD subspace of $W \times \{1\}$, $(Y^{q+n+1}, t: \nu_{Y^* W \times \{1\}} \to \mathbb{S}^n)$. The surgery obstruction of $t^{-1}(0) \cap \nu_{\partial Y} \to \partial Y^*$ is then 0. Thus to show bordism invariance of $\mathcal{O}$, we need only show that this construction on $(M \times I, H)$ gives the same obstruction as any other similar construction.

To show this, suppose we have $H: M \times I \to T(\xi)$ as above and two deformations of $H$ to $H'$ and $H''$ both relative to $M \times \{0\}$ and both s.f.h.t. on all of $M \times I$. Let $\tilde{H}: M^{q+n} \times I \times I \to T(\xi)$ be a homotopy between $H'$ and $H''$ with $\tilde{H}|M \times \{0\} \times I = (H|M \times \{0\}) \times I$ and $\tilde{H}|M \times \{1\} \times I$ contained in $T(\xi \cup U)$ where $U$ is a contractible neighborhood of $\ast$ in $X$. Then $H|M \times [I \times I \cup \{0\} \times I]$ is s.f.h.t. Since $H^*(M \times I \times I, M \times [I \times I \cup \{0\} \times I])$ is 0 we may shift $\tilde{H}$ to s.f.h.t. $\tilde{H}^{-1}(M_t) \cap M \times \{1\} \times I$ then is a $G$-framed PD bordism between $H'^{-1}(M_t) \cap M \times \{1\}$ and $H''^{-1}(M_t) \cap M \times \{1\}$. This shows the two surgery obstructions agree, and proves $\mathcal{O}$ is well defined.

We now check that these homomorphisms satisfy (i)-(iv) as claimed in the theorem.

(i) and (ii). The compatibilities claimed in (i) and (ii) follow easily from the analogous compatibilities for surgery obstructions, see [15] §§5 and 6.

(iii) Global transversality. We say that $f: M^{q+n} \to T(\xi)$ is
globally transversal if it is f.h.t. (but not necessarily f.h.t. on each simplex). If \( f \) is globally transversal, then \( f^{-1}(M_t) \) is a PD space of formal dimension \( n \). We will show here that if \( \mathcal{O}(M \times I, H) = 0 \), then we may deform \( H \) relative to \( M \times I \) to make it globally transversal and conversely if \( H \) may be deformed relative to \( M \times I \) until it is globally transversal then \( \mathcal{O}(M \times I, H) = 0 \).

If \( \mathcal{O}(M \times I, H) = 0 \), we deform \( H \) by a f.h.t. map to make \( H^{-1}(M_t) \cap M \times \{0\} \) connected and simply connected. Let \( J \) be the homotopy from the cone point to \( H'| M \times \{1\} \). The image of \( J \) is contained in \( T(\xi^q|U) \) where \( U \) is a contractible neighborhood of the base point in \( X \), and \( J \) of one end goes to the cone point. Thus we may shift \( J \) to be PL transverse relative to this end: Let \( Y^* \) be the preimage.

The element \( \mathcal{O}(M \times I, H) \) then is by definition the surgery obstruction of \( Y \cap M \times \{1\} \subset H^{-1}(M_t) \cap M \times \{1\} \). If it vanishes then we may do surgery by further shifts of \( J \) until \( Y \cap M \times \{1\} \subset H^{-1}(M_t) \cap M \times \{1\} \) is a homotopy equivalence. Then \( H' \cup J \) will be f.h.t. and homotopic relative to the ends to \( H \).

**Remark 2.5.** Note that \( \mathcal{O}(M \times I, H) \) is the surgery obstruction of a surgery problem where the domain bounds and the range is PD cobordant to \( H^{-1}(\mathcal{M}_t) \cap M \times \{0\} \). Note also that if \( \dim(M) = q + i \) with \( i \) odd, then the obstruction to transversality lives on the Bockstein of \( M \). That is, the obstruction to global transversality is \( \mathcal{O}(\delta M \times I, H|_{\delta M \times I}) \in P_{i-1} \).

Now suppose that \( H: M \times I \to T(\xi^q) \) is homotopic rel \( M \times \hat{I} \) to a globally transversal map. We wish to show that \( \mathcal{O}(M \times I, H) = 0 \). This will require a brief digression and alternative definition of \( \mathcal{O}(M \times I, H) \).

Roughly, we will deform \( H: M \times I \to T(\xi^q) \) rel \( M \times \{1\} \) (rather than \( M \times \{0\} \)) to a globally transversal map \( H' \) with respect to a smaller mapping cylinder \( \mathcal{M}'_t \subset \mathcal{M}_t \). We will do this in such a way that \( H^{-1}(\mathcal{M}_t) \) remains setwise fixed. It then follows from a slight
generalization of Lemma 1.4 that the inclusion \((H')^{-1}(\mathcal{M}_i) \cap M \times \{0\} \rightarrow H^{-1}(\mathcal{M}_i) \cap M \times \{0\}\) is a degree one normal map of PD spaces.

There are theories of surgery on PD spaces ([8], [18]), but for our applications, it is enough to observe that given a degree one normal map \(X \rightarrow Y\) of \(i\)-dimensional \(\mathbb{Z}/n\)-PD spaces, there is defined homotopy theoretically an obstruction \(s(X \rightarrow Y) \in P_i \otimes \mathbb{Z}/n\) ([3], [4]). \(s(X \rightarrow Y)\) an invariant of the normal bordism class of \(X \rightarrow Y\) and vanishes if \(X \rightarrow Y\) is a homotopy equivalence. If \(X\) is a PL-manifold, \(s(X \rightarrow Y)\) is the usual surgery obstruction.

We will argue that in the situation above, \(\mathcal{O}(M \times I, H) = s((H')^{-1}(\mathcal{M}_i) \cap M \times \{0\} \rightarrow H^{-1}(\mathcal{M}_i) \cap M \times \{0\})\). It follows that if \(H\) is globally transversal, then \(\mathcal{O}(M \times I, H) = 0\), since then \((H')^{-1}(\mathcal{M}_i) \rightarrow H^{-1}(\mathcal{M}_i)\) is a normal map of PD spaces with boundary equal to \((H')^{-1}(\mathcal{M}_i) \cap M \times \{0\} \rightarrow H^{-1}(\mathcal{M}_i) \cap M \times \{0\}\).

Now return to \(H: M \times I \rightarrow T(\xi)\). Let \(\mathcal{M}_i \subset \mathcal{M}_i\) be a slightly smaller mapping cylinder for \(\xi\). By Theorem 1.3.13 and Note 1.7, the obstruction theory allows us to deform \(H\) rel \(M \times \{1\}\) to a globally transversal map \(H'\) with respect to \(\mathcal{M}_i\), such that \(H^{-1}(\mathcal{M}_i)\) is kept setwise fixed throughout the deformation, provided that \(H^{-1}(\mathcal{M}_i) \cap \Delta^{s+j}\) contains a disc \(D^j\) for each cell \(\Delta^{s+j}\) of \(M \times I - M \times \{1\}\), \(j \geq 1\). So our first step is to run thickened arcs from \(H^{-1}(\mathcal{M}_i)\) to any such cell \(\Delta^{s+j}\) which does not intersect \(H^{-1}(\mathcal{M}_i)\). This can be interpreted as a deformation of \(H\) with does not change homotopy properties of the inclusion \(H^{-1}(\xi) \subset H^{-1}(\mathcal{M}_i)\). In particular, \(H^{-1}(\mathcal{M}_i) \cap M \times \{0\}\) remains a PD space.

This step provides us with our normal map of PD spaces \((H')^{-1}(\mathcal{M}_i) \cap M \times \{0\} \rightarrow H^{-1}(\mathcal{M}_i) \cap M \times \{0\}\). It is not difficult to use the obstruction theory in a similar manner to prove that the normal bordism class of this map is an invariant of the bordism class of the map \(M \rightarrow F_{\xi}\), which corresponds to \(H: M \times I \rightarrow T(\xi)\). Thus \(\mathcal{O}'(M \times I, H) = s((H')^{-1}(\mathcal{M}_i) \cap M \times \{0\} \rightarrow H^{-1}(\mathcal{M}_i) \cap M \times \{0\})\) is an invariant of the bordism class of \(M \rightarrow F_{\xi}\). To complete the proof of Theorem 2.4(iii), we need to prove that \(\mathcal{O}'(M \times I, H) = \mathcal{O}(M \times I, H)\).

Recall that \(\mathcal{O}(M \times I, H)\) is defined as follows. Deform \(H\) rel \(M \times \{0\}\) to a transversal map \(H'': M \times [0, 1] \rightarrow T(\xi)\) such that \(H''(M \times \{1\}) \subset T(\xi)\), where \(U\) is a contractible neighborhood of the basepoint of \(B_{\xi}\). Let \(J: M \times [1, 2] \rightarrow T(\xi)\) be the homotopy, given by the deformation of \(H\), from \(J|_{M \times \{1\}} \equiv H''|_{M \times \{1\}}\) to \(J|_{M \times \{2\}} \equiv \infty\), \(\infty \in T(\xi)\) the cone point. Using a PL-structure on \(\xi\), we may assume that \(J\) is PL-transversal to a smaller mapping cylinder \(\mathcal{M}_i \subset \mathcal{M}_i\). Then \(Y^* = J^{-1}(B_{\xi}^\circ)\) is a PL-manifold, and \(\partial Y^* = J^{-1}(B_{\xi}^\circ) \cap M \times \{1\} \rightarrow J^{-1}(\mathcal{M}_i) \cap M \times \{1\} = (H'')^{-1}(\mathcal{M}_i) \cap M \times \{1\}\) is a degree one normal map. By definition, \(\mathcal{O}(M \times I, H) = s(\partial Y^* \rightarrow (H')^{-1}(\mathcal{M}_i) \cap M \times \{1\})\).
Now, \( H'' \mid_{M \times \{1\}} \) is transversal with respect to both \( \mathcal{M}_\xi \) and \( \mathcal{M}_\nu \). We may as well assume, just as above, that \((H'')^{-1}(\mathcal{M}_\xi)\) meets all cells of \( M \times \{0, 1\} - M \times \{1\} \). Then we can deform \( H'' \) rel \( M \times \{1\} \) to \( H''' \), which is transversal with respect to \( \mathcal{M}_\nu \) on all of \( M \times [0,1] \), keeping \((H'')^{-1}(\mathcal{M}_\xi)\) setwise fixed. This gives a PD space with boundary, \( Z^\ast = (H''')^{-1}(\mathcal{M}_\nu) \subset (H'')^{-1}(\mathcal{M}_\xi) \), with \( Z^\ast \cap M \times \{1\} = \partial Y^\ast \). We now compute

\[
\mathcal{O}(M \times I, H) = \mathcal{O}((\partial Y^\ast) \to (H''')^{-1}(\mathcal{M}_\nu) \cap M \times \{1\}) \\
= \mathcal{O}(Z^\ast \cap M \times \{0\} \to (H''')^{-1}(\mathcal{M}_\nu) \cap M \times \{0\}) \\
= \mathcal{O}(M \times I, H'' \cup J) \\
= \mathcal{O}(M \times I, H)
\]

as desired.

Theorem 2.4(iii) is one of the key points of the paper. It is precisely here that we obtain a global obstruction to transversality (in a rather specific situation), using a call-by-cell obstruction theory. The remainder of the paper exploits this global obstruction.

(iv) **Product formulae.** Suppose we have \( H : M \times I \to T(\xi) \) as above, and we deform \( H \) relative to \( M \times \{0\} \) to \( H' \) which is s.f.h.t. Let \( (Y^\ast \subset M \times \{1\}, t : \nu_{Y^\ast \subset M \times \{1\}} \to \varepsilon^\ast) \) be the resulting \( G \)-framed PD subspace in \( M \times \{1\} \). If we cross \((M \times I, H)\) with \( L^\ast \) in the bordism of \( F_\nu \), then the new element is represented by

\[
M \times L \times I \overset{\pi}{\longrightarrow} M \times I \overset{H}{\longrightarrow} T(\xi)
\]

where we use a product triangulation on \( M \times L \). Thus we may shift \( H \circ \pi \) to \( H' \circ \pi \) which is s.f.h.t. in the product triangulation. The \( G \)-framed PD space in \( M \times L \times \{1\} \) is \((Y \times L, t)\). This shows that the surgery problem is just crossed with \( L \).

The product formulae in (iv) now follow from those in \([15], [22], \) and \([23] \) for ordinary surgery problems.

2.6. We have already observed that the open covers which we are considering are natural with respect to \( T(f) \) where \( f \) is a map of spherical fiber spaces which is simplicial on the base. From this
it follows easily that the homomorphisms on $F_\xi$ are also natural with respect to such maps.

3. The obstructions to global transversality. Let $\xi^q \to \beta^q_\xi$ be an oriented spherical fibration, with $\tau_\gamma(\beta^q_\xi) = 0$, and let $F^q_\xi \to W^q_\xi \to T^q_\xi$ be the fibration considered in §2. (We have suppressed the cover $\{V_\rho\}$ of $T^q_\xi$ from the notation.) In §2 we defined homomorphisms (if $q \geq 3$)

\[
\begin{align*}
\partial: & \Omega^{PL}_{q+i}(F^q_\xi) \to P_i \\
\partial_\iota: & \Omega^{PL}_{q+i}(F^q_\xi, \mathbb{Z}/n) \to P_i \otimes \mathbb{Z}/n \\
\tilde{\partial}: & \gamma^{PL}_{q+i}(F^q_\xi) \to P_i \otimes \mathbb{Z}/2. 
\end{align*}
\]

In this section we will work in the stable range; that is, we assume $i < q - 2$. We will use the homomorphisms $\partial$, $\partial_\iota$, $\tilde{\partial}$ to define homomorphisms on the bordism of $T^q_\xi$, which measure exactly the obstruction to global transversality, up to cobordism, of a map

\[
M^{q+i} \xrightarrow{f} T^q_\xi.
\]

Thus $S(M^{q+i}, f)$ is 0 if and only if $(M, f)$ is cobordant to a globally f.h.t. map. (See Def. 1.1.)

Stably, the fibration $F^q_\xi \to W^q_\xi \to T^q_\xi$ is also a cofibration. Thus, there is a natural isomorphism of bordism groups $\pi: \Omega^{PL}_{q+i}(W^q_\xi, F^q_\xi) \to \tilde{\Omega}^{PL}_{q+i}(T^q_\xi)$, $j < q - 2$. The map $\pi$ is described geometrically as follows. A relative bordism element $(\partial f, \partial M) \to (W^q_\xi, F^q_\xi)$ is defined by giving, first, a strongly fiber homotopy transversal map $f: M \to T^q_\xi$ and, secondly, a homotopy $F: \partial M \times I \to T^q_\xi$ of $f|\partial M$ to the trivial map. We obtain a bordism element $(D(M), g)$ of $T^q_\xi$ by doubling $M$, $D(M) = M \cup_{i \mu} (-M)$ and defining $g: D(M) \to T^q_\xi$ by setting $g| M$ to be $f$ and setting $g|_{-M}$ to be $F$ on a collar $\partial M \times I \subset (-M)$ and the trivial map outside this collar $\partial M \times I \subset (-M)$ and the trivial map outside this collar. Isomorphisms $\pi_\iota: \Omega_{q+i}(W^q_\xi, F^q_\xi, \mathbb{Z}/n) \xrightarrow{\Delta} \Omega^{PL}_{q+i}(T^q_\xi, \mathbb{Z}/n)$ and $\tilde{\pi}_\iota: \gamma_{q+i}(W^q_\xi, F^q_\xi) \xrightarrow{\Delta} \gamma^{PL}_{q+i}(T^q_\xi)$ are similarly defined if $j \leq q - 2$.

We now define homomorphisms

\[
\begin{align*}
s: & \tilde{\Omega}^{PL}_{q+i+1}(T^q_\xi) \to P_i \\
\tilde{s}_\iota: & \tilde{\Omega}^{PL}_{q+i+1}(T^q_\xi, \mathbb{Z}/n) \to P_i \otimes \mathbb{Z}/n \\
\tilde{s}: & \tilde{\Omega}^{PL}_{q+i+1}(T^q_\xi) \to P_i \otimes \mathbb{Z}/2
\end{align*}
\]

to be the compositions $(i < q - 3) s = o_\iota \pi^{-1}: \tilde{\Omega}^{PL}_{q+i+1}(T^q_\xi) \to \Omega^{PL}_{q+i+1}(W^q_\xi, F^q_\xi) \to \Omega^{PL}_{q+i+1}(F^q_\xi) \to P_i$ and similarly, $s_\iota = o_\iota \pi^{-1}$ and $\tilde{s} = \tilde{o}_\iota \tilde{\pi}^{-1}$.

**Lemma 3.1.** If $f: \xi^q \to \eta^q$ is a map of spherical fibrations, then
the diagram

\[
\begin{array}{ccc}
\tilde{\Omega}^{PL}_{q+i+1}(T^{q+1}_\xi) & \xrightarrow{s} & P_i \\
(T_f)_* & \downarrow & \\
\tilde{\Omega}^{PL}_{q+i+1}(T^{q+1}_\eta) & \xrightarrow{s} & \\
\end{array}
\]

commutes, and similarly for \( s_n \) and \( \bar{s} \).

(ii) \( s, s_n \), and \( \bar{s} \) satisfy the same compatibility relations as \( \mathcal{O}, \mathcal{O}_n \), and \( \tilde{\mathcal{O}} \). (See Theorem 2.4(i), (ii).)

(iii) \( s, s_n \) and \( \bar{s} \) satisfy the same product formulae as \( \mathcal{O}, \mathcal{O}_n \), and \( \tilde{\mathcal{O}} \). (See Theorem 2.4(iv).)

(iv) \( s, s_n, \) and \( \bar{s} \) are stable. That is, if \( i < q - 3 \)

\[
\tilde{\Omega}^{PL}_{q+i+1}(T^{q+1}_\xi) \times S^1 \xrightarrow{s} P_i \\
\tilde{\Omega}^{PL}_{q+i+1}(T^{q+1}_\xi) \oplus S^1 \xrightarrow{s} \\
\]

commutes, and similarly for \( s_n \) and \( \bar{s} \).

Proof. This is immediate from the definition of \( s, s_n, \) and \( \bar{s} \) in terms of \( \mathcal{O}, \mathcal{O}_n, \) and \( \tilde{\mathcal{O}} \).

Also, since the homomorphisms \( o, o_n \) and \( \bar{o} \) are defined as surgery obstructions, the homomorphisms \( s, s_n \) and \( \bar{s} \) are (indirectly) computed as surgery obstructions. For example, let \( f: (M, \partial M) \rightarrow (W_\xi, F_\xi) \) represent an element of \( \Omega^{PL}_{q+i+1}(W_\xi, F_\xi) \). This means we have a strongly transversal map \( g: M \rightarrow T^{q+1}_\xi \) and a homotopy to zero of \( g|_{\partial M} \). Let \( (V, \partial V) \subset (M, \partial M) \) be the \( (i + 1) \)-dimensional Poincaré pair \( (g^{-1}(B^{q+1}_\xi), \quad g^{-1}(B^{q+1}_\xi) \cap \partial M) \), defined by the transversal map \( g \). (We assume \( B^{q+1}_\xi \) is the mapping cylinder \( M_\xi \) of \( \xi^{q+1} \).) Then

\[
s\pi([M, \partial M, f]) = o([\partial M, f|_{\partial M}]) \in P_i
\]

is the surgery obstruction of degree one normal map \( L' \rightarrow L \), where \( L \) is PD cobordant to \( \partial V \) and \( L' \) is a PL manifold which is a boundary. (See Note 2.5.) Thus both the domain and range of the surgery problem used to compute \( s(x), x \in \tilde{\Omega}^{PL}_{q+i+1}(T^{q+1}_\xi) \), are PD boundaries. We conclude, for example,

3.2. \( s: \tilde{\Omega}^{PL}_{q+i+1}(T^{q+1}_\xi) \rightarrow P_{4i} = \mathbb{Z} \) is identically zero. In this case, \( s \) is computed as the difference of indices of two oriented boundaries.

Similarly, both the domain and range of the surgery problem used to compute \( s_n(y), y \in \Omega^{PL}_{q+i+1}(T^{q+1}_\xi, \mathbb{Z}/n) \) or \( \bar{s}(z), z \in \tilde{\Omega}^{PL}_{q+i+1}(T^{q+1}_\xi) \) are PD boundaries; in the first case, boundaries as \( \mathbb{Z}/n \) PD spaces and
Remark 3.3. 3.2 could also be established by appealing to the fact that $\tilde{\Omega}^{PL}_{q+i+1}(MSG_q)$ is finite and using naturality of $s$ with respect to bundle maps.

Theorem 3.4(i). Suppose $f: M \to T^q\xi$ represents an element of $\tilde{\Omega}^{PL}_{q+i+1}(T^q\xi)$ [resp. $\tilde{\Omega}^{PL}_{q+i+1}(T^q\xi)]$. If $s([M, f]) = 0$ [resp. $\tilde{s}([M, F]) = 0$], then $f: M \to T^q\xi$ is cobordant to a globally transversal map.

(ii) If $f: M \to T^q\xi$ represents an element of $\tilde{\Omega}^{PL}_{q+i+1}(T^q\xi, Z/n)$, $i$ even, [resp. $i$ odd] and $s_n([M, f]) = 0$ [resp. $s([\partial M, f|_{\partial M}) = 0$], then $f: M \to T^q\xi$ is cobordant to a globally transversal map.

Proof. Choose a relative bordism element $g: (N, \partial N) \to (W, F)$ such that $\pi([N, \partial N, g]) = [M, f]$ where $\pi$ is the doubling construction defined above. $g$ corresponds to a map $G: \partial N \times I \to T^q\xi$ with $G|_{\partial N \times 0}$ strongly transversal and $G|_{\partial N \times 1}$ the trivial map. By assumption $0 = \tilde{s}([M, F]) = \tilde{\partial}(\partial N \times I, G)$. Thus by Theorem 2.4(iii) we may assume that $G: \partial N \times I \to T^q\xi$ is globally transversal. It is then obvious (see figure below) that the induced map $\pi([N, \partial N, g]) = g \cup G: N \cup (-N) \to T^q\xi$ is globally transversal. This proves (i).

The proof of (ii) is essentially the same. There is the additional complexity that one must keep track of $Z/n$ manifolds with boundary in $\Omega^{PL}_q(W_q, F_q, Z/n)$, but we leave the details to the reader.

Our next goal will be to prove the converse of Theorem 3.4. In the process, we establish an alternate definition of the homomorphisms $s$ and $s_n$ on the bordism of $T^q\xi$, which is of independent interest.

There is a natural Pontrjagin-Thom isomorphism $\nu: \tilde{\Omega}^{PL}_{q+j}(T^q\xi) \sim \pi_{3q+j}(T^q\xi \Lambda MSPL_{2q}), j < q - 2$. Namely, given $f: M^{q+j} \to T^q\xi$, embed $M^{q+j} \subset S^{q+j}$ and cover $f$ by a map of bundles.
where $E^{2q}$ is the universal PL bundle. Now apply the Thom construction to obtain $S^{3q+j} \to T^{2q}_j \to (T^{2q}_x)^+\text{AMSPL}_{2q}$. Since $[M, f] \in \tilde{\Omega}^{PL}_{q+j}(T^{2q}_x) = \text{kernel}(\Omega^{PL}_{q+j}(T^{2q}_x) \to \Omega^{PL}_{q+j}(pt))$, we obtain a well-defined element of $\pi_{3q+j}(T^{2q}_x)^+\text{AMSPL}_{2q}$.

Now, $T^{2q}_x\text{AMSPL}_{2q}$ is itself a Thom space; namely, the Thom space of the Whitney sum $\xi^q \times E^{2q} \to \xi^q \times B\text{SPL}_{2q}$. From §2, there is a fibration $F_{q \times E} \to W_{q \times E} \to T^{2q}_x\text{AMSPL}_{2q}$ and $\pi_{3q+j}(F_{q \times E}) = P_j$. We thus define $s' = \tilde{\partial}p: \tilde{\Omega}^{PL}_{q+i+j}(T^{2q}_x) \to \pi_{3q+i+j}(T^{2q}_x)^+\text{AMSPL}_{2q} \to \pi_{3q+i+j}(F_{q \times E}) = P_j$.

Similarly, there is an isomorphism

$$p_n: \tilde{\Omega}^{PL}_{q+i+j}(T^{2q}_x, Z/n) \to \pi_{3q+i+j}(T^{2q}_x)^+\text{AMSPL}_{2q}, Z/n)$$

and we define $s'_n = \tilde{\partial}p_n: \tilde{\Omega}^{PL}_{q+i+j}(T^{2q}_x, Z/n) \to \pi_{3q+i+j}(T^{2q}_x)^+\text{AMSPL}_{2q}, Z/n) \to \pi_{3q+i+j}(F_{q \times E}, Z/n)$. It is easy to see that if $n$ is odd $\pi_{3q+i+j}(F_{q \times E}, Z/n) = Z/n, 0, 0, 0$ as $i \equiv 0, 1, 2, 3$ (mod 4), respectively, and, if $n$ is even, $\pi_{3q+i+j}(F_{q \times E}, Z/n) = Z/n, 0, Z/2, Z/2$ as $i \equiv 0, 1, 2, 3$ (mod 4), respectively. Moreover

$$s' = 0: \tilde{\Omega}^{PL}_{q+i+j}(T^{2q}_x) \to Z$$

and $s' = s'_n: \tilde{\Omega}^{PL}_{q+i+j}(T^{2q}_x, Z/n) \to \pi_{3q+i+j}(T^{2q}_x)^+\text{AMSPL}_{2q}, Z/n) \to \pi_{3q+i+j}(F_{q \times E}, Z/n)$.

**Theorem 3.5** (i). $s = s': \tilde{\Omega}^{PL}_{q+j}(T^{2q}_x) \to P_j$, (ii) $s_n = s'_n: \tilde{\Omega}^{PL}_{q+j+j}(T^{2q}_x, Z/n) \to P_j \otimes Z/n, j$ even.

**Proof.** Statement (i) is trivial if $j \equiv 0$ (mod 4) since $s = s' = 0$, and if $j \equiv 2$ (mod 4), statement (i) follows from (ii).

To prove statement (ii) if $j \equiv 0$ (mod 4), we will show that if $f: M \to T^{2q}_x$ represents an element of $\tilde{\Omega}^{PL}_{q+i+j}(T^{2q}_x)$ and $f|_{\delta M}: \delta M \to T^{2q}_x$ is globally transversal, with $(f|_{\delta M})^{-1}(B^{2q}_y) = L^{4i} \subset (\delta M)^{q+i}$ the associated PD space of dimension $4i$, then $s_n([M, f])$ and $s'_n([M, f]) \in Z/n$ are determined by the index of $L^{4i}$ modulo 8. (By 3.2 and 3.4(i), the hypothesis that $f|_{\delta M}$ is globally transversal puts no restriction on $[M, f] \in \tilde{\Omega}^{PL}_{q+i+j}(T^{2q}_x).$) First, we show that index $(L^{4i}) \text{ (mod 8)}$ depends only on the bordism class of $[\delta M, f|_{\delta M}]$.

From the definition of $p$ above, it is clear that $\alpha = p([\delta M, f|_{\delta M}]): S^{3q+4i} \to T^{2q}_x\text{AMSPL}_{2q}$ is global transversal: in fact

$$X^{4i} = T^{2q}_x \times (E^{2q}) \subset S^{3q+4i} \text{ and } L^{4i} = (f|_{\delta M})^{-1}(B^{2q}_y) \subset (\delta M)^{q+i}$$

are equivalent as PD spaces. By 1.3(3) and a slight generalization
of 1.4, we can homotope $\alpha: S^{q+4i} \rightarrow T_\xi^{q+4i}AMSPL_{\xi}$ to a strongly transversal map $\beta$ (see Def. 1.2) such that $Y^{4i} = \beta^{-1}(B_\xi^{2q} \times E^{2q}) \subset X^{4i}$ and $Y^{4i} \rightarrow X^{4i}$ is a degree one normal map. In particular, index $(L^{4i}) = \text{index} (X^{4i}) \equiv \text{index} (Y^{4i}) \pmod{8}$. Moreover, it is not difficult to show using the obstruction theory of §1 that index $(Y^{4i}) \pmod{8}$ depends only on the homotopy class of the strongly transversal map $\beta: S^{q+i\xi} \rightarrow T_\xi^{q}AMSPL_{2q}$. (In fact, $Y^{4i}$ is well-defined modulo cobordism of PD spaces and connected sum with the G-framed Milnor manifold $M^{4i}$ of index 8.) We conclude from this paragraph the following.

**Lemma 3.6.** If $g: N^{q+4i} \rightarrow T_\xi^{q}$ is globally transversal with $g^{-1}(B_\xi^{2q}) = K^{4i} \subset N^{q+4i}$ and if $[N, g] = 0 \in \tilde{\Omega}_{q+4i}(T_\xi^{q})$, then \text{index} $(K^{4i}) \equiv 0 \pmod{8}$.

Now we return to the $\mathbb{Z}/n$ bordism element $f: M \rightarrow T_\xi^{q}$, with $(f|_{_{M'}})^{-1}(B_\xi^{2q}) = L^{4i}$. By definition, $s_n([M, f]) \in \mathbb{Z}/n$ is computed as the surgery obstruction of a normal map of $4i$ dimensional $\mathbb{Z}/n$ PD spaces, $W' \rightarrow W$, (in fact, $W'$ is a PL manifold) where both $W'$ and $W$ bound as $\mathbb{Z}/n$ objects. This means that $dW = \partial V', \partial W = \partial V$ and $W' \cup (-nV') = \partial Q'$, $W \cup (-nV) = \partial Q$, where $V'$, $Q'$ are PL manifolds with boundary, $V, Q$ are PD spaces with boundary, dim $(V') = \text{dim} (V) = 4i$, and dim $(Q') = \text{dim} (Q) = 4i + 1$. Since the dimension is odd, we may assume that $\partial W' = \partial V' \rightarrow \partial V = \partial W$ is a homotopy equivalence. (There are no low dimensional problems since we are allowed cobordisms of both the domain $W'$ and the range $W$ of the surgery problem $W' \rightarrow W$.) Moreover, the closed PD space $K^{4i} = V \cup (-nV)$ can be identified with $(g|_{_{M'}})^{-1}(B_\xi^{2q})$, where $g: N \rightarrow T_\xi^{q}$ is a $\mathbb{Z}/n$ bordism element cobordant to $f: M \rightarrow T_\xi^{q}$. (Specifically, $[N, g]$ is constructed in terms of the map $\pi_{q+4i+1}(W, F, \mathbb{Z}/n) \rightarrow \tilde{\Omega}_{q+4i+1}(T_\xi^{q}, \mathbb{Z}/n)$.) By Lemma 3.6, index $(L^{4i}) = \text{index} (K^{4i}) \pmod{8}$. On the other hand, by the Novikov additivity property of the index, index $(K^{4i}) = \text{index} (V) - \text{index} (V')$, and also $0 = \text{index} (\partial Q') = \text{index} (W') - n \text{index} (V')$ and $0 = \text{index} (\partial Q) = \text{index} (W) - n \text{index} (V)$. Thus we have the following equation

$$\text{index} (W') - \text{index} (W) = n \text{index} (V) - n \text{index} (V')$$

$$= n \text{index} (K^{4i}).$$

Since $s_n([M, f]) \in \mathbb{Z}/n$ is defined as the mod $n$ reduction of the integer $(1/8) \text{index} (W') - \text{index} (W)$, we have proved the following.

**Lemma 3.7.** If $f: M^{q+4i+1} \rightarrow T_\xi^{q}$ is a $\mathbb{Z}/n$ bordism element and $f|_{_{M'}}$ is globally transversal with $L^{4i} = (f|_{_{M'}})^{-1}(B_\xi^{2q})$, let $I(L^{4i}) = \text{index} (L^{4i}) \pmod{8} \in \mathbb{Z}/8$. Then

(i) if $n = 2^r$, $s_n([M, f]) = 2^{-r}I(L^{4i}) \in \mathbb{Z}/2^r$,
(ii) if \( n \) is odd, \( s_n([M,f]) = 0 \).

(In 3.7(i), if \( r < 3 \), \( I(L^{4i}) \in 2^{r-2}Z/8Z \subset Z/8Z \). Thus, \( 2^{r-2}I(L^{4i}) \in Z/2^r \) makes sense.)

Finally, \( s'_n([M,f]) \) is also (indirectly) defined as the surgery obstruction of a normal map of \( Z/n \) P.D. spaces, via the identification

\[
\pi_{3q+4}F_1xS, Z[n] = P_i \otimes Z/n = Z/n. \quad \text{One can apply the same argument used in the proof of Lemma 3.7 to deduce that}
\]

\[
s'_n([M,f]) \in Z/n \quad \text{is determined by}
\]

\[
I(X^{4i}) \in Z/8, \quad \text{where}
\]

\[
X^{4i} = \alpha^{-1}(B^{2g} \times E^0), \quad \alpha = p([\delta M, f, \delta M]): S^{2q+4i} \longrightarrow T^{2g}AMSPL_{2q}.
\]

But we already know from the discussion preceding Lemma 3.6 that index \( (X^{4i}) = (L^{4i}) \). Thus, \( s'_n([M,f]) = s_n([M,f]) \in Z/n \). This proves Theorem 3.5(ii) if \( j \equiv 0 \mod(4) \).

If \( f: M^{4i+1} \rightarrow T^{2g} \) is a \( Z/2^r \) bordism element, \( s'_r([M,f]) \) and \( s'_r([\delta M, f]) \in Z/2^r \) depend only on the \( Z/2 \) reduction of \([M,f]\). That is, \( s'_r([M,f]) = s'_r([\delta M, f]) \) and \( s'_r([M,f]) = s'_r([\delta M, f]) \in Z/2^r \). Thus we assume \( M \) is a \( Z/2 \) manifold. Let \( N^6 \) be a \( Z/2 \) 6-manifold with \( \delta (\delta N^6) = 1 \in Z/2^r \). By Lemma 3.1(iii) and Theorem 2.4(iv), \( s_n([M,f],[N]) = s_n([M,f]) - s_n([\delta M, f]) \in Z/2^r \). Also from Theorem 2.4(iv) and the definition of \( s'_n([M,f],[N]) = s'_n([M,f]) \cdot d(\delta N^6) = s'_n([M,f]) \in Z/2^r \). Thus the case \( j \equiv 2 \mod(4) \) of Theorem 3.5(ii) follows from the case \( j \equiv 0 \mod(4) \) considered above. This completes the proof of Theorem 3.5.

We have now developed sufficient machinery to prove the converse of Theorem 3.4, in most cases.

**Theorem 3.8.** (i) If \( [M, f] \in \tilde{\Omega}_{q+j}^{pL}(T^{2g}) \)[resp. \( n_{q+j}^{pL}(T^{2g}) \)] and \( f: M \rightarrow T^{2g} \) is globally transversal, then \( s([M, f]) = 0 \)[resp. \( s([M, f]) = 0 \)].

(ii) If \( [M, f] \in \tilde{\Omega}_{q+j}^{pL}(T^{2g}, Z/n), j \) even, [resp. \( j \) odd] and \( f: M \rightarrow T^{2g} \) is globally transversal, then \( s_n([M, f]) = 0 \)[resp. \( s([\delta M, f]) = 0 \)].

**Proof.** We will postpone the unoriented case of 3.8(i) until Chapter IV. The oriented case of 3.8(i) has content only if \( j \equiv 2 \mod(4) \), and follows from 3.8(ii) with \( n = 2, j = 2 \mod(4) \).

To prove 3.8(ii) with \( j \equiv 0 \mod(4) \), we observe that if \( f: M^{4i+1} \rightarrow T^{2g} \) is globally transversal, with \( f^{-1}(\delta N^6) = K^{4i+1} \subset M^{4i+1} \) a \( Z/n \) PD space with \( \delta K^{4i+1} = L^{4i} \subset \delta M \), then \( 0 = \text{index}(\delta K^{4i+1}) = n \text{index}(L^{4i}) \subset Z \), hence index \( (L^{4i}) = 0 \). Thus, by Lemma 3.7, \( s_n([M, f]) = 0 \). The case \( j \equiv 2 \mod(4) \) is deduced from the case \( j \equiv 0 \mod(4) \) by crossing with \( N^6 \) where \( d(\delta N^6) = 1 \in Z/2^r \), just as in the proof of Theorem 3.5. The case \( j \) odd of 3.8(ii) follows from 3.8(i).

**Remark 3.9.** Lemmas 3.6 and 3.7, along with the trick of crossing
with $N^\sigma, d(\delta N^\sigma) = 1 \in \mathbb{Z}/2$, imply that the homomorphisms
\[ s_n: \Omega^{PL}_{q+i+1}(T_{\xi}^n, \mathbb{Z}/n) \rightarrow P_i \otimes \mathbb{Z}/n \]
(and hence also $s: \tilde{\Omega}^{PL}_{q+i+1}(T_{\xi}^n) \rightarrow P_i$) are independent of the cover \{\$V_\rho\$\} of $T_{\xi}^n$ which occurs implicitly in the original definition of $s_n$. We will prove in Chapter IV that $s: \eta^{q+i+1}(T_{\xi}^n) \rightarrow P_i \otimes \mathbb{Z}/2$ is also independent of the cover \{\$V_\rho\$\}.

We have shown above that if $f: M^{q+i} \rightarrow T_{\xi}^n$ is a map, $M$ a closed oriented manifold, then $f: M \rightarrow T_{\xi}^n$ is cobordant to a globally transversal map $g: N \rightarrow T_{\xi}^n$ (3.2 and Theorem 3.4) and, moreover, if $L^{q+i} = g^{-1}(B_{\xi}^q) \subset N^{q+i}$, index $(L^{q+i}) \in \mathbb{Z}/8$ is an invariant of $[M, f] \in \Omega^{PL}_{q+i+1}(T_{\xi}^n)$ (Lemma 3.6). However, we have given no indication of how one might compute index $(L^{q+i}) \in \mathbb{Z}/8$. Similarly, we have defined
\[ s_n: \Omega^{PL}_{q+i+1}(T_{\xi}^n, \mathbb{Z}/n) \rightarrow P_i \otimes \mathbb{Z}/n \]
and proved that $s_n$ is exactly the obstruction to global transversality, up to cobordism (Theorem 3.8). But we have not discussed how $s_n(P_{q+i+1}, h) \in P_i \otimes \mathbb{Z}/n$ might be computed if $h: P_{q+i+1} \rightarrow T_{\xi}^n$ is a $\mathbb{Z}/n$ manifold, although Lemma 3.7 reduces this question to the evaluation of an index. The following discussion remedies these defects to some extent, and will prove useful in §9.

Let $\pi: \xi^q \rightarrow B_{\xi}^q$ be a spherical fibration. Let $M_\xi \subset T_{\xi}^n$ be the mapping cylinder of $\pi$; that is, $M_\xi = \xi^q \times [0, 1] \cup_{\xi^q \times 0} B_{\xi}^q$. Let $M'_\xi \subset M_\xi$ be a “smaller” mapping cylinder. Say $M'_\xi = \xi^q \times [0, 1/2] \cup_{\xi^q \times 0} B_{\xi}^q$. It makes sense to say that a map is transversal with respect to either $M_\xi$ or $M'_\xi$ (see Definition 1.1).

**Definition 3.10.** Let $f: M^{q+i} \rightarrow T_{\xi}^n$ be a map, $M$ a closed manifold. A partition of $f: M \rightarrow T_{\xi}^n$ consists of two codimension zero submanifolds $U_1$ and $U_2$ of $M$ such that $M = U_1 \cup U_2, \partial U_1 = U_1 \cap U_2 = \partial U_2$, and such that $f|_{U_1}: U_1 \rightarrow T_{\xi}^n$ is transversal with respect to $M_\xi$ and $f|_{U_2}: U_2 \rightarrow T_{\xi}^n$ is transversal with respect to $M'_\xi$. 

\[ L_2 = g^{-1}(M'_\xi) \cap U_2 \]
\[ L_1 = g^{-1}(M) \cap U_1 \]
Let $L_i = f^{-i}(M_i) \cap U_i$, $L_2 = f^{-i}(M_2) \cap U_i$, as in the figure. Thus $L_i$ is an $i$-dimensional PD space with boundary, $j = 1, 2$. By Lemma 1.4, the inclusion $\partial L_2 \to \partial L_1$ is naturally a degree one normal map of PD spaces.

Let us assume $i = 4n$, $f: M^{q+4n} \to T^q_8$ partitioned as above. Then there is defined an invariant $\Theta(\partial L_2 \to \partial L_1) \in Z/8$, [15], [4], [13]. Namely, let $K_{2n-1}$ be the torsion subgroup of kernel $(H_{2n-1}(\partial L_2, Z) \to H_{2n-1}(\partial L_1, Z))$. The normal bundle map $\nu_{2L_2} \to \nu_{2L_1}$ covering $\partial L_2 \to \partial L_1$ can be used to define a quadratic function $\psi: K_{2n-1} \to Q/Z$, refining the natural linking pairing on $K_{2n-1}$. Let $\Theta(\partial L_2 \to \partial L_1) = \operatorname{Arf}(\psi) \in Z/8$.

If $W^{4n} \to \partial L_i$ is any normal cobordism between $\partial L_2 \to \partial L_1$ and a homotopy equivalence, then $\Theta(\partial L_2 \to \partial L_1) = \operatorname{index}(W^{4n}) \in Z/8$. Thus if we could do “Poincaré surgery” on $\partial L_2 \to \partial L_1$ to a homotopy equivalence, we could prove that $f = f_i: M^{q+4n} \to T^q_8$ is homotopic to a transversal map $f_i: M^{q+4n} \to T^q_8$, and, if $L^{4n} = f_i^{-1}(B^q_8)$, then $\operatorname{index}(L^{4n}) = \operatorname{index}(L) + \operatorname{index}(L_2) - \Theta(\partial L_2 \to \partial L_1) \in Z/8$. We assert that even without Poincaré surgery we can establish this last formula.

That is,

**Lemma 3.11.** Let $M^{q+4n} = U_1 \cup_2 U_2$ be a partition as above, $L_1^{4n} \subset U_1$. If $f: M^{q+4n} \to T^q_8$ is bordant to a transversal map $g: N^{q+4n} \to T^q_8$, with $L^{4n} = g^{-1}(B^q_8) \subset N^{q+4n}$, then $\operatorname{index}(L^{4n}) = \operatorname{index}(L) + \operatorname{index}(L_2) - \Theta(\partial L_2 \to \partial L_1) \in Z/8$.

**Proof.** The idea is the same as that used in the proof of Lemma 3.6. Namely, by a Pontrjagin-Thom construction, we define $p = p([M, f]): S^{q+4n} \to T^q_8 \Lambda \text{MSPL}_{12q}$. Moreover, we preserve the partition, that is, we embed $(M^{q+4n}; U_1 \cup_2 U_2)(S^{q+4n}; D_+, D_-)$, where $D_\pm$ are upper and lower hemispheres. It is easy to see that then $p: S^{q+4n} \to T^q_8 \Lambda \text{MSPL}_{12q}$ is partitioned, $S^{q+4n} = D_+ \cup_2 D_-$, with the same transversal inverse images $L_1^{4n} \subset D_+^{q+4n}$, $L_2^{4n} \subset D_-^{q+4n}$, $\partial L_i \subset \partial L_i \subset S^{q+4n-1} = D_+ \cap D_-$. (Strictly speaking, $L_1^{4n}$ and $L_2^{4n}$ are replaced by their thickenings.)

But we know that the two transversal maps $S^{q+4n-1} \to T^q_8 \Lambda \text{MSPL}_{12q}$

\[
\begin{array}{c}
D_+ \quad S^{q+4n+1} \quad D_-\\
L_1 \quad \psi^{4n} \quad L_2
\end{array}
\]
defined by \( \partial L_2 \subset S^{4n+1} \) and \( \partial L_1 \subset S^{4n+1} \) are homotopic. Moreover, there is no obstruction in this dimension to deforming a homotopy, rel the boundary, to a transversal homotopy, with transversal inverse image \( W_4 \subset S^{4n+1} \times I \). (See figure above.) Then index \( (W^*) = \Theta(\partial L_2 \to \partial L_1) \) and the lemma follows since index \( (L^*) = \text{index}(L_1) + \text{index}(L_2) \) — index \( (W) \).

Lemma 3.11 reduces certain index computations to computation of a \( \Theta \)-invariant. We state here some product formulae for evaluating \( \Theta \) which will be used in §9. For proofs see [14], [5].

**Lemma 3.12.** (i) Let \( f: M^a \to N^b \) be a degree one normal map of closed PD spaces, and let \( L_1 \) be a closed PD space, \( a + b \equiv 3 \pmod{4} \). Then \( \Theta(M^a \times L^b \to N^a \times L^b) = 0 \) if \( a \equiv 0, b \equiv 3 \pmod{4} \) \( \Theta(M^a \times L^b \to N^a \times L^b) = 4S_2(M^a \to N^a) \cdot d(L^b) \) if \( a \equiv 2, b \equiv 1 \pmod{4} \). (Here \( S_2(M^a \to N^a) \in \mathbb{Z}/2 \) is the Kervaire obstruction, which is defined homotopy theoretically, \( d(L^b) \in \mathbb{Z}/2 \) is the de Rham invariant.)

(ii) Let \( f: p^a \to q^b \) be a normal map of \( \mathbb{Z}/2^r \) and \( 4: \mathbb{Z}/2 \to \mathbb{Z}/8 \) PD spaces, and let \( R^b \) be a \( \mathbb{Z}/2^r \) PD space, \( a + b \equiv 0 \pmod{4} \). Form the normal map of closed PD spaces \( \delta(P \times R) = P \times \delta R \bigcup_{\delta(Q \times R)} \delta P \times R \)

\[
(f \times 1) \cup (\delta f \times 1) \to \delta(Q \times R) = Q \times \delta R \bigcup_{\delta(Q \times R)} \delta Q \times R.
\]

Then

\[
\Theta(\delta(P^a \times R^b)) \longrightarrow \delta(Q^a \times R^b)) = 0 \text{ if } a \equiv 0, b \equiv 0 \pmod{4}
\]

\[
\Theta(\delta(P^a \times R^b)) \longrightarrow \delta(Q^a \times R^b)) = 0 \text{ if } a \equiv 1, b \equiv 3 \pmod{4}
\]

\[
\Theta(\delta(P^a \times R^b)) \longrightarrow \delta(Q^a \times R^b)) = 4d(\delta R)S_2(p^a \to q^b)
\]

\[
\text{if } a \equiv 2, b \equiv 2 \pmod{4}
\]

\[
\Theta(\delta(P^a \times R^b)) \longrightarrow \delta(Q^a \times R^b)) = 4d(R^b)S_2(\delta P \to \delta Q)
\]

\[
\text{if } a \equiv 3, b \equiv 1 \pmod{4}.
\]

Now let \( f: P^{a+1} \to T^q \) be a \( \mathbb{Z}/n \) manifold.

**Definition 3.13.** A \( \mathbb{Z}/n \) partition of \((P, f)\) consists of two codimension zero \( \mathbb{Z}/n \) submanifolds with boundary, \( U_1 \) and \( U_2 \subset P \), such that \( P = U_1 \bigcup_{U_2} \delta U_1, \delta U_2, f|_{U_1}: U_1 \to T^q \) is transversal with respect to the mapping cylinder \( M_t \subset T^q \) and \( f|_{U_2}: U_2 \to T^q \) is transversal with respect to \( M_t \subset M_t \).

The transversal inverse images \( L_1^{-1} = f^{-1}(M_t) \cap U_1 \) and \( L_2^{-1} = f^{-1}(M_t) \cap U_2 \) are also \( \mathbb{Z}/n \) manifolds with boundary. Moreover, \( \partial L_1 = f^{-1}(M_t) \cap U_1 \cup U_2 \) is also \( \mathbb{Z}/n \) manifolds with boundary. Moreover, \( \partial L_1 = f^{-1}(M_t) \cap U_1 \cup U_2 \) is also \( \mathbb{Z}/n \) manifolds with boundary. Moreover, \( \partial L_1 = f^{-1}(M_t) \cap U_1 \cup U_2 \cup f^{-1}(M_t) \cap U_1 \cap U_2 \neq \partial L_1 \), and the inclusion \( \partial L_1 \to \partial L_1 \) is a degree one normal map of \( \dot{i} \)-dimensional, \( \mathbb{Z}/n \) PD spaces.
Given a normal map \( M^i \to N^i \) of \( \mathbb{Z}/n \) PD spaces, we can define a "surgery obstruction" \( S_n(M^i \to N^i) \in P_i \otimes \mathbb{Z}/n \) as follows:

\[
S_n(M^i \to N^i) = \frac{1}{8} (\text{index } (M^i) - \text{index } (N^i) - n\Theta(\delta M \to \delta N)) \in \mathbb{Z}/n
\]

\[
S_n(M^{i-2} \to N^{i-2}) = S_n(M \to N) \in \mathbb{Z}/2 \otimes \mathbb{Z}/n
\]

Thus \( S_n \) is defined homotopy theoretically for PD spaces, without any knowledge of PD surgery. \( S_n \) is an invariant of the normal bordism class of \( M \to N \), and clearly vanishes if \( M \to N \) is a homotopy equivalence.

**Theorem 3.14.** If \( P = U \sqcup U_j \) is a \( \mathbb{Z}/n \) partition of \( f: P^{q+i+1} \to T_\xi^q \), with transversal inverse images \( L_j^{q+1} \subset U_j^{q+i+1}, j = 1, 2, \) as above, then

\[
S_n([P^{q+i+1}, f]) = S_n(\partial L_2 \to \partial L_0) \in P_i \otimes \mathbb{Z}/n
\]

**Proof.** If \( i \equiv 0(\text{mod } 4) \) this follows from Lemma 3.11, the definition of \( S_n \) in terms of the index and \( \Theta \), and the proof of Lemma 3.7. We leave the details for the reader.

If \( i \equiv 2 \) (mod 4), cross with \([L'], \) where \( d(\partial L') = 1 \in \mathbb{Z}/2 \) and use Lemmas 3.1(iii) and 3.12(ii).

We conjecture that given any \( f: M^{q+i+1} \to T_\xi^q, M \) a closed or a \( \mathbb{Z}/n \) manifold, partitions always exist. If so, we could then use PD surgery to prove that \( S([M, f]) \in P_i \) or \( S_n([M, f]) \in P_i \otimes \mathbb{Z}/n \) was exactly the obstruction to homotoping \( f: M^{q+i+1} \to T_\xi^q \) to a transversal map.

4. Geometric bundle structures and fiber homotopy transversality. Let \( \xi \) be a spherical fiber space, \( \tilde{T}(\xi) \) the total singular complex of the Thom space, \( \tilde{W}_i \) the complex of f.h.t. maps \( \mathcal{A} \to T(\xi) \). We have a natural inclusion \( \tilde{W}_i \subset \tilde{T}(\xi) \). The geometric realization of \( \tilde{T}(\xi) \) is canonically homotopy equivalent to \( T(\xi) \). If \( X \xrightarrow{f} \tilde{T}(\xi) \), then a lift of \( f \) through \( \tilde{W}_i \) is the same thing as a deformation of \( f \) into the subcomplex \( \tilde{W}_i \), i.e., \( F: X \times I \to \tilde{T}(\xi) \) with \( F_0 = f \) and \( F_1(X) \subset \tilde{W}_i \). Two such lifts (or deformations) are equivalent (concordant) if and only if there is a homotopy between them which is constant on \( X \times \{0\} \) and which keeps \( X \times \{1\} \) in \( \tilde{W}_i \). We say two PL structures are equivalent if they are concordant.

In [11] it is shown that an equivalence class of PL structures for \( \xi \) gives a well defined equivalence class of deformation retracts of \( \tilde{T}(\xi) \) into \( \tilde{W}_i \) (i.e., lifts of \( \tilde{T}(\xi) \to \tilde{T}(\xi) \)). These deformations are given by homotopies of \( \mathcal{A} \to T(\xi) \) to a PL transverse map. If we do this construction universally we have
This same construction works relative to an open cover, and may be done so that all 2-dimensional preimages are homotopy equivalent to 2-manifolds. Thus we have

\[
\begin{aligned}
\bar{W}_{SG(q)} & \rightarrow MSG(q) \\
\downarrow_{l_{PL}} & \searrow \\
MSPL(q) & \to
\end{aligned}
\]

where \( WSG(q) \) is the space of strongly f.h.t. maps small with respect to the cover of \( BSG(q) \cdot l_{PL} \) is again defined by \( PL \) transversality and is well defined up to equivalence as a lift. In this section we shall construct a lifting of

\[
\begin{aligned}
\bar{W}_{SG(q)} & \rightarrow MSG(q) \\
\downarrow_{l_{TOP}} & \searrow \\
MSTOP(q) & \to
\end{aligned}
\]

which will commute with \( l_{PL} \) up to equivalence as a lift.

The lack of a topological transversality theorem in dimension 4 prevents us from defining this lifting directly. We use instead an enhanced version of the "crossing with \( CP^2 \)" trick of Sullivan, [23].

Let \( M^n \) be a closed, oriented, connected, simply connected manifold. Define \( \bar{T}(\xi)^{\omega} \) to be a semi-simplicial complex whose \( i \)-simplices are maps \( \Delta^i \times M^n \rightarrow \bar{T}(\xi) \) which are contained in one of the sets in the open cover constructed in \( \S \, 1 \), i.e., all of \( \Delta^i \times M^n \) is contained in one of the open sets. Let \( W^\omega_i \) be all the above maps which are globally fiber homotopy transverse on \( \Delta^i \times M^n \) and on all faces \( \Delta^j \times M^n \). In addition we require that whenever the preimage has dimension 2, that the PD space with boundary be the homotopy type of a 2-manifold with boundary. Let \( F_i(M) \) be the homotopy theoretic fiber of

\[
W^\omega_i \longrightarrow \bar{T}(\xi)^{\omega}.
\]

Theorem 4.1. (a) \( \pi_i(F_i q(M^n)) \cong P_{i+n-q-1} \) if \( q \geq 3, q \geq n - 1 \), and \( M^n \) is closed, oriented, connected and simply connected

(b) if in addition \( \dim M = 0(4) \), then

\[
\times M^n; F_i \longrightarrow F_i(M^n)
\]

induces multiplication by \( I(M^n), \pi_*(F_i) \rightarrow \pi_*(F_i(M^n)) \).
Proof. (a) Given a map \( \mathcal{A}^i \times M^n \to T(\xi^q) \) which is f.h.t. on \( \partial \mathcal{A}^i \times M^n \); with \( \xi^q \) admitting a PL structure, use PL transversality to produce a surgery problem of dimension \( i + n - 1 - q \). Taking its obstruction gives a map \( \pi_*(F_{\xi^q}(M^n)) \to P_{i+n-q-1} \). The same arguments as in 2.1 show that this map is an isomorphism for \( i \neq 2 \) and \( i + n \neq 3 + n \). When \( i + n = 3 + n \) we use the fact that the two dimensional PD space in \( \partial \mathcal{A}^i \times M^n \) is homotopy equivalent to a PL manifold, to know that if the obstruction in \( P_* \) vanishes then surgery to a homotopy equivalence is possible. When \( i = 2 \), we have the extra difficulty that \( \partial \mathcal{A}^i \times M^n \) is not simply connected. Thus our surgery problem is not necessarily one with trivial fundamental group but rather one with fundamental group \( \mathbb{Z} \). If \( q \geq n - 1 \), then the dimension of the surgery problem in \( \partial \mathcal{A}^i \times M^n \) is \( n + 1 - q \leq 2 \). Thus having fundamental group \( \mathbb{Z} \) causes no trouble.

(b) Obviously \((\times M^n)\) induces maps

\[
\begin{align*}
F_i^* & \longrightarrow W_i^* \quad \longleftarrow \quad T(\xi^q) \\
\downarrow zM & \quad \downarrow zM \\
F_i(M^n) & \longrightarrow W_i^{x^n} \quad \longleftarrow \quad T(\xi^q)^{x^n}
\end{align*}
\]

We see easily that the induced map on the fibers crosses the surgery problems involved with \( M^n \). Thus it multiplies the surgery obstruction by the signature of \( M^n \). Since \( \pi_*(F_i^*) \) and \( \pi_*(F_i(M)) \) are identified by surgery obstructions to \( P_* \), this proves part (b).

**Corollary 4.2.** If \( M^n \) is closed, oriented, connected, simply connected and of index 1, then \((\times M^n)\) induces a homotopy equivalence

\[
F_i^* \times M^n \longrightarrow F_i(M^n) .
\]

**Corollary 4.3.** Given \( X \xrightarrow{j} MSG \) and \( M^n \) as above, then lifts of \( j \) to \( W_{SG} \) are in natural 1-1 correspondence with liftings of \( \times M^n \circ j \) to \( W_{SG}^J \).

\[
\begin{align*}
F_{SG(q)}(M^n) & \longrightarrow W_{SG(q)}^x \longrightarrow MSG(q)^M \\
\uparrow \times M & \quad \uparrow \times M \\
F_{SG(q)} & \longrightarrow W_{SG(q)} \longrightarrow MSG(q)
\end{align*}
\]
Now we use topological transversality to give a lifting of $MSTOP(q) \to MSG(q) \to MSG(q)^{CP^2}$. Use topological transversality inductively on simplices of dimension $\leq q + 3$ and then cross with $CP^2$. This gives a lifting on the $(q + 3)$-skeleton of $MSTOP(q)$. On the $(q + 4)$-skeleton we have $\mathbb{A}^{q+4} \times CP^2, \eta \to MSG(q)$

$\eta$ is topologically transverse on the boundary with preimage of dimension 7. Thus we can apply relative topological transversality to shift $\eta$ transverse. Continue in this manner up the skeleta of $MSTOP(q)$, using only that $q + n + 4 > q + 4$. This provides the lift, and a similar argument proves any two such lifts are equivalent. Thus by corollary 4.3 we have a well defined equivalence class of lifts $W_{SG(q)} \to MSG(q)$

**Theorem 4.4.** The lift induced on $MSPL(q)$ by the above lift on $MSTOP(q)$ agrees with any lift produced by PL transversality.

$MSPL(q) \xrightarrow{\rho} MSTOP(q) \xrightarrow{l_{top}} MSG(q)$

i.e., $l_{top} \circ \rho$ is equivalent as a lift to $l_{PL}$.

**Proof.** To show this we need only show that it is true after crossing with $CP^2$. After crossing with $CP^2$ compatibility of the lifts comes from the fact that PL transversality and topological transversality are compatible.

In [11] it is proved that for a spherical fiber space $\xi^q$ over a four-connected space $X$, there is a 1-1 correspondence between equivalence classes of PL structures on $\xi^q$ and liftings. $W_{SG(q)} \to MSG(q)$

The correspondence is as follows. If $\tilde{f}: X \to BSPL(q)$ is a lifting of $f: X \to BSG(q)$, the classifying map for $\xi^q$, then we form $T(\xi^q) \xrightarrow{T(\tilde{f})} MSPL(q) \xrightarrow{l_{PL}} W_{SG(q)}$. 

\[ T(\xi^q) \xrightarrow{T(\tilde{f})} MSPL(q) \xrightarrow{l_{PL}} W_{SG(q)} \]
which is the lifting of $T(f): T(\xi) \to \MSG(q)$. We now wish to strengthen this theorem by replacing $\overline{W}_{SG(q)}$ by $W_{SG}$.

**Theorem 4.5.** If $X$ is a connected, simply connected space, and $\xi^q \to X$ is a spherical fiber space which is classified by $f: X \to BSG(q)$ then there is a natural one-to-one correspondence between topological structures on $\xi^q$ and liftings.

$$l: T(\xi^q) \to WSG \text{ of } T(f): T(\xi) \to \MSG(q).$$

The correspondence is given by

$$\mathcal{F}: T(\xi^q) \to WSG$$

where

$$\mathcal{F}: \{i_{TOP} \circ T(\xi^q): T(\xi) \to MSTOP(q) \to WSG(q)\}.$$

**Proof.** The argument proceeds exactly like the one in [11]. Namely we work one simplex at a time supposing we have a spherical fiber space $\xi^q \to D^{i+1}$, a topological structure $E \to \xi|\partial D^{i+1}$, and an extension of strong fiber homotopy transversality over all of $\xi^q$. Using this we show that the topological structure extends in a unique way so that topological transversality (after we cross with $CP^q$) agrees with the strong f.h.t. (after crossing with $CP^q$). Essentially we have shown that the obstruction to extending the f.h.t. over $\xi$ in all of $D^{i+1}$ is naturally identified with an element in $P_1$ and all such elements occur as obstructions. Of course $P_i$ is naturally identified with $\pi_i(G/TOP)$ and the topological structure on $\xi|\partial D$ gives an element in $\pi_i(G/TOP)$ which is the obstruction to extending the PL structure over $\xi \to D^{i+1}$. What we show is that these two obstructions are the same element just as in [11]. This argument works in all dimensions since $\pi_i(F_{\xi^q}) \cong P_i - q - 1$ in all dimensions; whereas the argument in [11] only works in dimensions $> 4$ since the low homotopy groups of the fiber of $\overline{W}_{\xi^q} \to T(\xi^q)$ are unknown.

**Chapter II**

5. $F_{\xi^q}$, $G/TOP$, and localization at 2. In this section we use the results of §2 and an argument similar to one in [11] to prove that $F_{\xi^q}$ is naturally homotopy equivalent to copy of $G/TOP$ shifted $q$ dimensions. This result is a slight strengthening of the one in [11] in that the map constructed here is an isomorphism on all the homotopy groups where as the one in [11] is only an isomorphism on the high ($\geq 5$) dimensional groups. The argument is the same. The improvement in this version is that by strengthening the notion of fiber homotopy transversality in dimension 2 we get a hold on the low dimensional homotopy of $F_{\xi^q}$. 
The results in [23] and [9] give a canonical equivalence \( \Omega'(G/TOP) \) with \( G/TOP \times Z \). Let \( G/TOP^q \) be the \( q \)-connected cover of \( G/TOP \). Define \( G/TOP<q> \) to be \( \Omega^q(G/TOP^q) \) for any \( j \) such that \( 4j > q \). This is independent of \( j \) (as long as \( 4j > q \)) by the fact that \( \Omega G/TOP \cong G/TOP \times Z \). \( \Omega G/TOP<q> = G/TOP<q-1> \), \( G/TOP<0> = G/TOP \) and \( G/TOP<q> \) is \( q \)-connected.

**Theorem 5.1.** (a) There exist canonical homomorphisms

1. \( \Omega_*(G/TOP<q>; Z/k) \rightarrow P_{*-q} \)
2. \( \Omega_*(G/TOP<q>; Z/k) \rightarrow P_{*-q} \otimes Z/k \)

satisfying (a) \( \sigma \) and \( \sigma_k \) are compatible with \( Z \rightarrow Z/k \) and \( Z/k \rightarrow Z/k \).

(b) \( \sigma \) is multiplicative with respect to the index

(c) \( \sigma_k \) for \( k \) odd is multiplicative with respect to the index

(d) \( \sigma_k((M^{m+q}, f) \otimes N*) = \begin{cases} \sigma_k(M, f) \cdot I(N) & n \equiv 0(4) \\ \sigma_k(M, f) \cdot d(\delta N) & m \equiv n \equiv 2(4) \\ \sigma_k(f \cdot \delta M) \cdot d(N) & m \equiv 3, n \equiv 1(4) \\ 0 & \text{otherwise} \end{cases} \)

(b) \( G/TOP<q> \) is universal with respect to these homomorphisms in the category of \( q \)-connected spaces.

**Note 1.** When we say that \( G/TOP<q> \) is universal with respect to these homomorphisms in the category of \( q \)-connected spaces we mean that given \( X \) \( q \)-connected and homomorphisms

\( \Omega_*(X; Z) \rightarrow P_{*-q} \) and \( \Omega_*(X; Z/k) \rightarrow P_{*-q} \otimes Z/k \)

satisfying (a) through (d) above, then there is a unique homotopy class of maps \( X \rightarrow G/TOP<q> \) such that \( f^*\sigma = \tau \) and \( f^*\sigma_k = \tau_k \) for all \( k \).

**Note 2.** It follows from the usual universality argument that the homomorphisms satisfying (a) through (d) above completely determine \( G/TOP<q> \).

**Sketch of proof of 5.1** Case I \( q = 0 \). The surgery obstruction maps, \( S \) and \( S_k \) give the required homomorphisms on \( \Omega_*(G/TOP) \) and \( \Omega_*(G/TOP; Z/k) \). In [23] and [15] it is proved that they satisfy (a) through (d) in the theorem and that \( G/TOP \) is universal with respect to them.

Case II \( q = 4l \). \( G/TOP<4l> \rightarrow G/TOP^4 \). Thus we have a map
Let $\sigma = \pi^* S$ and $\sigma_k = \pi^* S_k$. The range of $\sigma$ is $P_* = P_{*-4l}$ if $* > 4l$ and the range of $\sigma_k$ is $P_* \otimes \mathbb{Z}/k = P_{*-4l} \otimes \mathbb{Z}/k$ if $* > 4l$. Thus in dimensions greater than $4l$, $\sigma$ and $\sigma_k$ have the correct ranges. In dimension less than or equal to $4l$ the bordism groups of $G/\text{TOP}(4l)$ are 0 and thus the ranges of $\sigma$ and $\sigma_k$ are 0 as they are supposed to be. $\sigma$ and $\sigma_k$ clearly satisfy (a)–(d) since $S$ and $S_k$ do.

To show that $\{G/\text{TOP}(4l), \sigma, \text{ and } \sigma_k\}$ are universal let $\tau$ and $\tau_k$ be given a bordism of $X$ satisfying (a) through (d). Again identifying $P_{*-4l}$ with $P_*$ for $* \geq 4l$ we use $\tau$ and $\tau_k$ to define a unique map, $f$

\[
\begin{array}{ccc}
X & \xrightarrow{f} & G/\text{TOP}\\
\downarrow & & \downarrow \pi\\
G/\text{TOP} & \xrightarrow{\pi} & G/\text{TOP}(4l)
\end{array}
\]

with $f^* S = \tau$ and $f^* S_k = \tau_k$. This map factors uniquely through $G/\text{TOP}(4l)$ since $X$ is $4l$-connected.

**Case III**  
$q$ arbitrary. In this case we pick $4l > q$ and use the fact that $\Omega_{*+4} G/\text{TOP}(4l) = G/\text{TOP}(q)$. We define $\sigma$ and $\sigma_k$ on $G/\text{TOP}(q)$ to be

\[
\Omega_{*+4}(G/\text{TOP}(4l)) \longrightarrow \Omega_{*+4+4l}(G/\text{TOP}(4l)) \longrightarrow P_{*+4l}
\]

and

\[
\Omega_{*+4}(G/\text{TOP}(4l); \mathbb{Z}/k) \longrightarrow \Omega_{*+4+4l}(G/\text{TOP}(4l); \mathbb{Z}/k) \longrightarrow P_{*+4l} \otimes \mathbb{Z}/k
\]

where $\sigma'$ and $\sigma_k'$ are the maps from case II on $G/\text{TOP}(4l)$.

The homomorphisms are easily checked to satisfy (a)–(d) and to be universal.

Apply 5.1 to $F_\xi q$, $q \geq 3$, and the homomorphisms of Theorem 2.4 we have a canonical map

\[
F_\xi q \xrightarrow{\rho_q} G/\text{TOP}(q)
\]

which is natural with respect to spherical fiber space maps which are simplicial on the base.

**Theorem 5.2.**  
$\rho_q$ is a homotopy equivalence.

**Proof.** We have an isomorphism, $\mathcal{O} \circ h$
For the universal homomorphisms on $G/TOP(q)$ the analogous statement is true. That is, the composition below is an isomorphism

$$\pi_i(G/TOP(q)) \xrightarrow{\rho_i} \Omega_i(G/TOP(q)) \xrightarrow{\partial} P_{i-q}.$$ 

Since $(\rho_i)^*\rho = \partial$, we see that $\rho_i^*$ is an isomorphism on $\pi_i$ for all $i$.

Now we wish to specialize to the prime 2. According to [15] the homomorphisms give cohomology classes in $G/TOP, \mathcal{L} \in H^n(G/TOP; \mathbb{Z}_2)$ and $\mathcal{K} \in H^{n+1}(G/TOP; \mathbb{Z}/2)$. These classes are uniquely determined by cohomological formulae involving them which determines the homomorphism $S$ and $S^2$. The formulae are:

1. $\Omega_{n+1}(G/TOP; \mathbb{Z}/2) \to P_{n+2} \otimes \mathbb{Z}/2 = \mathbb{Z}/2 \otimes \mathbb{Z}/2 = \mathbb{Z}/2$ is given by
   $$s(M, f) = \langle f^*\mathcal{K} \cdot V^q(M), [M] \rangle.$$

2. $\Omega_n(G/TOP) \xrightarrow{S} P_n = \mathbb{Z}$ and $\Omega_{n+1}(G/TOP, \mathbb{Z}/2) \xrightarrow{S^2} P_{n+1} \otimes \mathbb{Z}/2^2 = \mathbb{Z}/2^2$ are given by $S(M, f) = \langle f^*\mathcal{L} \cdot \mathcal{L}_M, [M] \rangle$ and
   $$\langle \delta^*(f^*\mathcal{K} \cdot V^q(M)), [M] \rangle.$$

Here $\mathcal{L}_M$ is a $\mathbb{Z}_2$ characteristic class of $M$ lifting the rational Hirzebruch $\mathcal{L}$-class, $V^q(M)$ means the $\mathbb{Z}/2$ characteristic class

$$(\sum V_i(M))(\sum Sq^i V(M)),$$

and $\delta^*$ is the $\mathbb{Z}/2$ integral Bockstein. See [23] and [15] for proofs.

There are analogous classes and formulae $G/TOP(q)$. The classes in $G/TOP(4l)$ are obtained by pulling back the ones in $G/TOP$ under the natural map $G/TOP(4l) \xrightarrow{\pi} G/TOP$. The classes and homomorphisms still satisfy the same formulae by naturality. The classes in $G/TOP(q)$ are then obtained from those in $G/TOP(4j)4j > q$, by looping. Once again since both the classes and homomorphisms are obtained in this way the formulae are still satisfied in $G/TOP(q)$.

Using $\rho_{4q}: F_{4q} \to G/TOP(q)$ to pull back the classes to $F_{4q}$, we see that we have classes $\mathcal{K} \in H^{n+2+q}(F_{4q}; \mathbb{Z}/2)$ and $\mathcal{L} \in H^{n+1}(F_{4q}; \mathbb{Z}_2)$ satisfying:

**Theorem 5.3.** (1) The obstruction homomorphism

$$\mathcal{O}: \Omega_{n+2+q}(F_{4q}; \mathbb{Z}/2) \to \mathbb{Z}/2$$

is given by

$$\mathcal{O}(M, f) = \langle f^*\mathcal{K} \cdot V^q(M), [M] \rangle.$$

(2) The homomorphisms $\mathcal{O}: \Omega_{n+1}(F_{4q}; \mathbb{Z}_2) \to \mathbb{Z}_2$ and
The obstruction to global transversality

\[ s_\circ: \Omega^{j+q}_*(F; \mathbb{Z}/2) \to \mathbb{Z}/2 \]

is given by

\[ s_\circ([M, f]) = \langle V^*(M) \cdot f^* \Phi(\mathcal{H}), [M] \rangle \in \mathbb{Z}/2. \]

The homomorphisms \( s_r: \Omega^{j+q+1}_*(T_\xi^q, \mathbb{Z}/2) \to \mathbb{Z}/2 \) are given by:

\[ s_r([M, f]) = \langle \mathcal{L}(M) \cdot f^* \Phi(\mathcal{L}), [M] \rangle + i \langle VSq^1 V(\delta M) \cdot (f \circ \delta)^* \Phi(\mathcal{H}), [\delta M] \rangle \in \mathbb{Z}/2, \]

where

\[ i: \mathbb{Z}/2 \to \mathbb{Z}/2' \]

is the inclusion.

The classes \( \mathcal{H} \) and \( \mathcal{L} \in \mathbb{H}^*(BSG, \mathbb{Z}/2) \) are uniquely determined by these formulae.

6. Geometric bundle structures, localized at 2. In this section
we continue to focus our attention on information at the prime 2. We will show that if we use the classes \( \mathcal{X} \) and \( \mathcal{Z} \) defined in §5 to form

\[
BSG_{(2)} \xrightarrow{\mathcal{X} \times \mathcal{Z}} \prod_{i \geq 1} K(\mathbb{Z}/2, 4i - 1) \times K(\mathbb{Z}_{(2)}, 4i + 1)
\]

then the homotopy theoretic fiber admits a natural equivalence with \( BSTOP_{(2)} \) i.e.,

\[
BSTOP_{(2)} \xrightarrow{\eta(2)} BSG_{(2)} \xrightarrow{\mathcal{X} \times \mathcal{Z}} \prod_{i \geq 1} K(\mathbb{Z}/2, 4i - 1) \times K(\mathbb{Z}_{(2)}, 4i + 1)
\]

is a fibration where \( \eta(2) \) is the localization at 2 of the natural map \( \eta: BSTOP \to BSG \).

The map of \( BSTOP_{(2)} \) into the fiber of \( (\mathcal{X} \times \mathcal{Z}) \) is obtained from the localization at 2 of the lifting

\[
\xymatrix{ MSTOP(q) \ar[r] \ar[d] & \tilde{W} \ar[d] \cr MSG(q) \ar[r]_l & G/TOP(q + 1)_{(2)} \}
\]

constructed in §4 by applying the Thom isomorphism. Thus

\[
\xymatrix{ W_{\tilde{q}} \ar[r] & MSG(q)_{(2)} \ar[r] & G/TOP(q + 1)_{(2)} \cr MSTOP(q)_{(2)} \ar[r]_l & BSTOP(q)_{(2)} \ar[u]_l \}
\]

after applying the Thom isomorphism gives

\[
\xymatrix{ X \ar[r] & BSG(q)_{(2)} \ar[r] & G/TOP(1)_{(2)} \cr BSTOP(q)_{(2)} \ar[u]_l & \ar[r] & \ar[u]_l \}
\]

That \( l \) is a homotopy equivalence is essentially a reformulation (by applying the Thom isomorphism) of the Theorem 4.5 that a topological structure for \( \hat{\xi}^r \) is equivalent to a section of

\[
W_{\hat{q}} \longrightarrow \tilde{T}(\hat{\xi}^r) .
\]

Let \( X \) be the fiber of \( (\mathcal{X} \times \mathcal{Z}) \)

\[
X \longrightarrow BSG_{(2)} \xrightarrow{\mathcal{X} \times \mathcal{Z}} \prod_{i \geq 1} K(\mathbb{Z}/2, 4i - 1) \times K(\mathbb{Z}_{(2)}, 4i + 1) .
\]

Stabilizing the results of §4, we have a fibration of spectra

\[
F_{SG} \longrightarrow W_{SG} \longrightarrow MSG
\]
Since we are in a stable category, the fibration is also a cofibration and extends to the right as follows

\[
\begin{array}{c}
F_{SG} \longrightarrow WSG \longrightarrow MSG \longrightarrow \Sigma F_{SG}.
\end{array}
\]

Localizing at 2 we have

\[
\begin{array}{c}
F_{SG_{(2)}} \longrightarrow WSG_{(2)} \longrightarrow MSG_{(2)} \longrightarrow \Sigma F_{SG_{(2)}},
\end{array}
\]

From this we shall produce a canonical lifting of \( BSTOP_{(2)} \rightarrow BSG_{(2)} \) to \( BSTOP_{(2)} \rightarrow X \), using a stronger version of the Thom isomorphism.

Let \( \Pi \) be a product of Eilenberg-MacLane spaces, and \( \Pi \langle q \rangle \) another product which is \( q \)-connected and with \( \Omega^q \Pi \langle q \rangle \sim \Pi \).

Then there is a map, well defined up to homotopy,

\[
K(Z, q) \times \Pi \longrightarrow \Pi \langle q \rangle
\]
given by cupping with \( \zeta_q \), the fundamental class of \( K(Z, q) \). We may arrange this map so that \( \rho(\ast \Pi) = \ast \).

**Lemma 6.1.** Let \( \xi^q \rightarrow B \) be an oriented \( q \)-dimensional spherical fiber space. Then we have a natural homotopy equivalence

\[
\begin{array}{c}
\Pi^B \cup \text{Thom class} \longrightarrow (\Pi \langle q \rangle, \ast)^{(T(\xi^q), \ast)}. \\
\end{array}
\]

**Note.** The statement on \( \pi_0 \) translates to \( H^*(B) \cup \text{Thom class} \rightarrow H^{q+q}(T(\xi^q)) \) is an isomorphism.

**Proof.** Let \( U \in H^q(T(\xi^q); Z) \) be the Thom class.

Let \( \tilde{U} : (T(\xi^q), \ast) \rightarrow (K(Z, q), \ast) \) be a representative for \( U \). Define

\[
\begin{array}{c}
\Pi \longrightarrow \Pi \langle q \rangle \rightarrow (D(\xi^q), S(\xi^q)) \rightarrow (D(\xi^q), S(\xi^q)) \times B \longrightarrow K(Z, q) \times \Pi \longrightarrow \Pi \langle q \rangle.
\end{array}
\]

We identify \( T(\xi^q) \) with \( D(\xi^q) / S(\xi^q) \). Notice also that the base point of \( T(\xi^q) \) goes to \( \rho(\ast, \Pi) = \ast \). Thus we have a map \( \Pi^B \longrightarrow (\Pi \langle q \rangle, \ast)^{(T(\xi^q), \ast)} \).

On \( \pi_0 \) it is just the usual map \( H^*(B) \cup \text{Thom class} \rightarrow H^{q+q}(T(\xi^q)) \) and thus is an isomorphism. We now show that it is an isomorphism on \( \pi_\ast \). Since \( \Pi^B \) and \( \Pi \langle q \rangle \) are \( H \)-spaces it suffices to show that \( \mu_\ast : [S^i, \Pi^B] \rightarrow [S^i, (\Pi \langle q \rangle, \ast)^{(T(\xi^q), \ast)}] \) is a bijection.

\[
\begin{array}{c}
[S^i, \Pi^B] = \pi_\ast(H^*(B \times S^i)) = H^*(S^i) \\
[S^i, (\Pi \langle q \rangle, \ast)^{(T(\xi^q), \ast)}] = \pi_\ast[\Pi \langle q \rangle, \ast)^{(T(\xi^q) \times S^i, \ast)}].
\end{array}
\]
But
\[(T(\xi^q) \times S^i)/(\ast \times S^i) = T(\xi^q) \wedge (S^i^+) = T(\xi^q) \wedge (S^i \to pt) = T(\xi^q \times 1_{S^i}),\]
where \(\xi^q \times 1_{S^i} \to B \times S^i\) is the product fiber space. Thus
\[\{S^i, (\pi(q, \ast)^{T(\xi^q, \ast)}\} = H^*(T(\xi^q \times 1_{S^i})).\]
The map induced by \(\mu^\ast\) from \(H^*(B \times S^i)\) to \(H^*(T(\xi^q \times 1_{S^i}))\) is easily seen to be \(\cup (U \otimes 1)\) which is the Thom class of this bundle. This proves the lemma.

We now apply this lemma to the fibration
\[\xymatrix{ WSG_{(2)} \ar[r] & MSG_{(2)} \ar[r] & \Sigma FSG_{(2)} \ar[d] \ar[r] & \ar[d] \prod_{i \leq 1} K(Z/2, 4i - 1 + q) \times K(Z/(2), 4i + 1 + q). }
\]
The lifting \(l_{\topop_{(2)}}\) is equivalent to a deformation of
\[\Phi(\Sigma^\ast) \times \Phi(\Sigma^\ast) \circ \Phi(\eta_{(2)}) = \Phi(\Sigma^\ast \times \Sigma^\ast \circ \eta_{(2)}) \to \ast.\]
The previous lemma applied to \(\pi_0\) and \(\pi_1\) of the mapping spaces tells us that \((\Sigma^\ast \times \Sigma^\ast) \circ \eta_2\)
\[X \xrightarrow{j} BSG_{(2)} \xrightarrow{\tilde{\Sigma}^\ast \times \tilde{\Sigma}^\ast} \prod_{i \leq 1} (Z/2, 4i - 1) \times (Z/(2), 4i + 1) \]
is homotopic to \(*\), and, in fact picks out up to homotopy a homotopy \((\Sigma^\ast \times \Sigma^\ast) \circ \eta_{(2)}\) to \(*\). This is equivalent to a lift of \(\eta_{(2)}\) to the fiber \(X, \tilde{l}_{\topop} : BSTOP_{(2)} \to X.\)

**Theorem 6.2.** \(\tilde{l}_{\topop}\) is a homotopy equivalence.

*Proof.* Theorem 4.5 says that if \(B\) is 1-connected and \(f : B \to BSG\), then liftings of \(f\) to \(BSTOP\).

\[
\xymatrix{ & BSTOP \ar[d] \ar[dl]_{\tilde{l}_{\topop}} \ar[dl]_{\tilde{f}} \ar[dr]^{n} \ar[dr]^{f} \ar[dr] & \\
B & & & BSG \ar[u]_{\tilde{f}} \ar[u]_{\tilde{l}_{\topop}} }
\]
are in natural 1–1 correspondence with liftings \(\mu\) of \(T(f)\).
where $\xi$ is the spherical fiber space over $B$ induced by $f$. The correspondence is $\tilde{f} \mapsto l_{TOP} \circ T(\tilde{f})$.

Localizing at 2, we see that liftings

$$
\begin{array}{c}
B \\
\xymatrix{ f_{(2)} & B \ar[l] & \simeq) \\
\ar[d] & \ar[d] & \ar[d] \\
B_{STOP} & B_{SG} \ar[l] & B_{SG} \ar[l]^1
}\end{array}
$$

are in natural 1-1 correspondence with liftings

$$
\begin{array}{c}
WGS \\
\xymatrix{ T(\xi) & \ar[l] & MSG \ar[d] \\
\ar[d] & \ar[d] & \ar[d] \\
WGS_{(2)} & \ar[l] & MSG_{(2)} \ar[l]^1
}\end{array}
$$

The correspondence is given by

$$
\tilde{f}_{(2)} \mapsto l_{TOP} \circ T(\tilde{f})
$$

Let

$$
\begin{array}{c}
S \xymatrix{ g & X \ar[l] & BSG_{(2)} \ar[l] & \simeq) \ar[l] & \ar[l] \\
\ar[d] & \ar[d] & \ar[d] & \ar[d] & \ar[d] \\
S \ar[r] & B_{STOP} \ar[l] & B_{SG} \ar[l]^1
}\end{array}
$$

\[ \prod K(Z/2, 4i - 1) \times K(Z_{(2)}, 4i + 1) \]

The previous lemma gives a lifting

$$
\begin{array}{c}
WGS_{(2)} \\
\xymatrix{ T(\xi) & \ar[l] & MSG_{(2)} \ar[d] \\
\ar[d] & \ar[d] & \ar[d] \\
WGS_{(2)} & \ar[l] & MSG_{(2)} \ar[l]^1
}\end{array}
$$

where $\rho$ is the bundle over $S$ induced by $f \circ g$. This is equivalent, by the above discussion, to a lifting

$$
\begin{array}{c}
BSTOP_{(2)} \\
\xymatrix{ \simeq) & \ar[l] & BSG_{(2)} \ar[d] \\
\ar[d] & \ar[d] & \ar[d] \\
BSTOP_{(2)} \ar[l]^1 & \ar[l]^1 & BSG_{(2)} \ar[l]^1
}\end{array}
$$
\( \check{g} \) is the unique lifting (up to equivalence) for which \( l_{\text{top}} \circ T(f): T(\rho) \to \text{MSTOP}_{(2)} \to \text{WSG}_{(2)} \) is homotopic as a lifting to \( \omega \). Applying the previous lemma again, we see that \( \check{\text{top}} \circ \check{g} \) is homotopic to \( g \) for exactly one homotopy class of maps \( \check{g}: S^i \to \text{BSTOP}_{(2)} \). Thus \( \check{\text{top}} \) is an \( \equiv \) on \( \pi_i \) for \( i > 1 \). Since \( X \) is the fiber of

\[
\text{BSG}_{(2)} \to \prod_{i \geq 1} K(\mathbb{Z}/2, 4i - 1) \times K(\mathbb{Z}_{(2)}, 4i + 1)
\]

the homotopy exact sequence of a fibration implies that \( X \) is connected and simply connected as is \( \text{BSTOP}(2) \). Thus \( \check{\text{top}}: \text{BSTOP}_{(2)} \to X \) is a homotopy equivalence.

7. The cohomology suspension of the classes \( \tilde{\mathcal{Z}} \) and \( \tilde{\mathcal{Z}}' \). In §5 we defined classes \( \tilde{\mathcal{Z}} \in H^{*-1}(\text{BSG}, \mathbb{Z}/2) \) and \( \tilde{\mathcal{Z}}' \in H^{*-1}(\text{BSG}, \mathbb{Z}_{(2)}) \) which are obstructions to transversality in the Thom space \( \text{MSG} \). Our goal in this section is to study \( \sigma(\tilde{\mathcal{Z}}) \in H^{*-2}(\text{SG}, \mathbb{Z}/2) \) and \( \sigma(\tilde{\mathcal{Z}}') \in H^{*-1}(\text{SG}, \mathbb{Z}_{(2)}) \), where the cohomology suspension \( \sigma: H^*(\text{BSG}) \to H^{*-1}(\text{SG}) \) is induced by the natural map \( \Sigma \text{SG} \to \text{BSG} \). We shall show that \( \sigma(\tilde{\mathcal{Z}}) \) and \( \sigma(\tilde{\mathcal{Z}}') \) are the classes induced from the surgery classes in \( G/\text{TOP} \) by the natural map \( G \to G/\text{TOP} \).

There is a fibration

\[
G_q/\text{TOP}_q \xrightarrow{j} \text{BSTOP}_q \to \text{BSG}_q.
\]

The bundle over \( G_q/\text{TOP}_q \) is the universal topological \( q \)-bundle together with a fibre homotopy trivialization \( t \), \( t \) corresponds to a map of Thom spaces \( \tau: M(G_q/\text{TOP}_q) \to S^q \) of degree one on the bottom cell. Moreover, the following diagram commutes

\[
\begin{array}{ccc}
S^q & \xrightarrow{t} & M(G_q/\text{TOP}_q) \\
\downarrow & & \downarrow j \\
\text{MSG}_q & \rightleftharpoons & \text{MSTOP}_q
\end{array}
\]

where the unnamed maps are the obvious maps of Thom spaces.

We have constructed natural fiber homotopy transversality structures on both \( \text{MSTOP}_q \) and \( S^q \); \( q \geq 3 \); that is, liftings of \( \text{MSTOP}_q \) and \( S^q \) to \( \text{WSG}_q \). This provides two liftings, \( l_{\text{top}} \circ j \) and \( l_q \circ t \) of \( M(G_q/\text{TOP}_q) \) to \( \text{WSG}_q \), as in the diagram follows:
If we work in the stable range, or with spectra, we thus obtain a "difference element" \( d: M(G/TOP) \rightarrow F \), \( d = l_{TOP} \circ j - l_e \circ t \).

Using the homomorphisms of §2, \( \mathcal{O}: \Omega_{*+q}(F') \rightarrow P_* \) and

\[
\mathcal{O}_*: \Omega_{*+q}(F', \mathbb{Z}/n) \rightarrow P_* \otimes \mathbb{Z}/n ,
\]
we constructed in §5 cohomology classes

\[
\mathcal{K} \times \mathcal{L}: F_q \rightarrow \prod_{i \geq 1} K(\mathbb{Z}/2, q + 4i - 2) \times K(\mathbb{Z}_{(2)}, q + 4i) .
\]

Stably, we can form the composition \((\mathcal{K} \times \mathcal{L}) \circ d: M(G_q/TOP_q) \rightarrow F_q \rightarrow \prod_{i \geq 1} K(\mathbb{Z}/2, q + 4i - 2) \times K(\mathbb{Z}_{(2)}, q + 4i)\).

**Theorem 7.1.** The map \((\mathcal{K} \times \mathcal{L}) \circ d\) coincides under the Thom isomorphism with the cohomology classes \( \mathcal{K} \in H^{*-2}(G_q/TOP_q, \mathbb{Z}/2) \) and \( \mathcal{L} \in H^*(G_q/TOP_q, \mathbb{Z}_{(2)}) \), defined by the surgery obstruction homomorphisms \( S: \Omega_*(G_q/TOP_q) \rightarrow P_* \) and \( S_q: \Omega_*(G_q/TOP_q, \mathbb{Z}/n) \rightarrow P_* \otimes \mathbb{Z}/n \).

On the other hand, consider the fibrations

\[
SG \xrightarrow{\mathcal{K} \times \mathcal{L}} \prod_{i \geq 1} K(\mathbb{Z}/2, 4i - 2) \times K(\mathbb{Z}_{(2)}, 4i) \longrightarrow X \longrightarrow BSG_{(2)}
\]
of §6, where

\[
X = \text{Fiber} \left( \prod_{i \geq 1} K(\mathbb{Z}/2, 4i - 1) \times K(\mathbb{Z}_{(2)}, 4i + 1) \right) .
\]

By Theorem 6.2, the two lifts in the diagram

\[
WSG_{(2)} \rightarrow MSG_{(2)} \quad \text{and} \quad M(G/TOP)
\]
correspond to two lifts in the diagram

\[
X \rightarrow BSG_{(2)} \quad \text{and} \quad G/TOP
\]
with a corresponding difference element \( \Delta : G/TOP \to \prod_{i \geq 2} K(\mathbb{Z}/2, 4i - 2) \times (\mathbb{Z}/2, 4i) \). But the lift of 0: \( G/TOP \to BSG_{(2)} \), corresponding to the lift \( \ell \circ t \) on the Thom space, is the 0 lift, 0: \( G/TOP \to X \). From this remark and Theorem 7.1 it follows that the difference element \( \Delta \) is \( \mathcal{X} \times \mathcal{L} \) and that the following diagram commutes

\[
\begin{array}{ccc}
\prod_{i \geq 2} K(\mathbb{Z}/2, 4i - 2) \times K(\mathbb{Z}/2, 4i) & \longrightarrow & X \\
\sigma(\mathcal{X} \times \mathcal{L}) & & \\
\downarrow & & \\
SG & & BSG_{(2)} \\
\downarrow \mathcal{X} \times \mathcal{L} & & \\
G/TOP & \longrightarrow & BSTOP \\
\end{array}
\]

**Corollary 7.2.** \( \sigma(\mathcal{X}) = i^*(\mathcal{X}) \in H^{*-2}(SG, \mathbb{Z}/2) \) and \( \sigma(\mathcal{L}) = i^*(\mathcal{L}) \in H^{*-n}(SG, \mathbb{Z}/2) \).

Thus we see that the suspensions of the transversality obstructions \( \mathcal{X} \) and \( \mathcal{L} \) in \( BSG \) are simply the surgery obstruction classes in \( SG \). We now return to the proof of Theorem 7.1.

**Proof of 7.1.** For simplicity, we will prove 7.1 for \( G/PL \) rather than \( G/TOP \). This certainly suffices for Corollary 7.2.

The surgery obstruction homomorphisms \( S : \Omega^{\ast q}(G_{q}/PL_q) \to P_{\ast} \) and \( S_n : \Omega^{\ast q}_{n}(G_{q}/PL_q, \mathbb{Z}/n) \to P_{\ast} \otimes Z/n \) have Thom space analogues \( \mathcal{S} : \Omega^{\ast q}(L(G_{q}/PL_q), \mathbb{Z}/n) \to P_{\ast} \otimes Z/n \) defined by composing \( S \) and \( S_n \) with the \( PL \) bordism Thom isomorphism \( \Omega^{\ast q}_{n}(M(G_{q}/PL_q)) \to \Omega^{\ast q}(L(G_{q}/PL_q), \mathbb{Z}/n) \), and similarly with \( Z/n \) coefficients. The cohomology classes \( \Phi(\mathcal{X}) \in H^{*-2+q}(M(G_{q}/PL_q), \mathbb{Z}/2) \) and

\[
\Phi(\mathcal{L})H^{*-2+q}(M(G_{q}/PL_q), \mathbb{Z}/2)
\]

are then defined in terms of \( \mathcal{S} \) and \( \mathcal{S}_n \) by formulae which are identical to the formulae defining \( \mathcal{X} \in H^{*-2+q}(F_q, \mathbb{Z}/2) \) and \( \mathcal{L} \in H^{*-2+q}(F_q, \mathbb{Z}/2) \) in terms of \( \mathcal{S} : \Omega^{\ast q+1}(F_q) \to P_{\ast} \) and \( \mathcal{S}_n : \Omega^{\ast q+1}_{n}(F_q, \mathbb{Z}/n) \to P_{\ast} \otimes Z/n \). (See §5 for these formulae.) Theorem 7.1 then follows from

(7.3) \( \mathcal{S} = \mathcal{S}_n \circ \Omega^{\ast+q}(M(G_{q}/PL_q)) \to \Omega^{\ast+q}(F_q) \to P_{\ast} \) and

\[
\mathcal{S}_n = \mathcal{S}_n \circ \Omega^{\ast+q}_{n}(M(G_{q}/PL_q), \mathbb{Z}/n) \to \Omega^{\ast+q}_{n}(F_q, \mathbb{Z}/n) \to P_{\ast} \otimes Z/n.
\]

To prove 7.3, we must examine the "difference construction" \( d = l \circ \mathcal{S} - l \circ t : M(G_{q}/PL_q) \to F_q \) more closely. Let us picture a cell \( \alpha : A^{q+i} \to MSG_q \) by:
and a cell of $WSG_q$ by:

![Diagram 1]

where the band is the PD space given by transversality. We picture a deformation $\Delta^{q+i} \times I \rightarrow MSG_q$ of $\alpha$ to $WSG_q$ by

![Diagram 2]

A cell of $F_q$ is pictured:

![Diagram 3]

where the shaded top face means the map is to the basepoint of $MSG_q$. We will work in the stable range, $i \ll q$, and assume all our cells have a "suspension coordinate" in the direction of the arrow below:

![Diagram 4]

Cells of $F_q$ then "act" on deformations of $\alpha$ by suspension addition, or juxtaposition:
followed by the obvious equivalence of

\[ \alpha \quad \text{and} \quad \alpha \]

With these definitions one shows for complexes \( X \) with \( \dim(X) \ll 2q \) that if \( f: X \to MSG_q \) can be deformed to \( WSG_q \), then equivalence classes of deformations of \( f \) correspond bijectively with \([X, F_q]\).

Now consider a cell \( \alpha: \Delta^{q+s+1} \to M(G_q/PL_q) \). We picture the deformation \( l_{PL} \circ j(\alpha) \) defined by \( PL \) transversality by:

where \( L^i \), the core of the band on the bottom face, is a \( PL \) manifold and the band is a tubular neighborhood of \( L^i \). We picture the deformation \( l_{pt} \circ t(\alpha) \) defined by the fibre homotopy trivialization of \( M(G_q/PL_q) \) followed by transversality for the trivial bundle,
where $L'$ is a framed submanifold of the tubular neighborhood of $L$.

The following picture gives a cell, $d(\alpha)$, of $F_q$:

$$
(7.4)
$$

where the map on the top half is a canonical homotopy of $\alpha - \alpha$ to the trivial map. It is easy to see that the deformation $l_{\mathcal{L}} \circ t(\alpha) + d(\alpha)$ is equivalent to $l_{\mathcal{L}} \circ j(\alpha)$. Thus $d(\alpha)$ represents the difference construction $l_{\mathcal{L}} \circ j(\alpha) - l_{\mathcal{L}} \circ t(\alpha) : \mathcal{S}^q \to F_q$.

If we have, instead of a single cell, a manifold $f : M^{q+i} \to M\langle G_\mathcal{L}/PL_\mathcal{L} \rangle$, we get $d(f) : M \to F_q$ by iterating the construction above over the cells of $M$. This produces a PL submanifold $L^i \subset M^{q+i}$ and a framed submanifold $L'$ of the tubular neighborhood $V_{L^i}$. It is easy to see from the definition of $\mathcal{O} : \Omega_{q+i} (M\langle G_\mathcal{L}/PL_\mathcal{L} \rangle) \to P_\mathcal{L}$ above that

$$
\mathcal{O}([M, f]) = S(L' \to L) \in P_\mathcal{L},
$$

and similarly for $\mathcal{O}$ if $M$, and hence $L'$ and $L$, are $\mathbb{Z}/\mathbb{n}$ manifolds.

On the other hand, from §2, $\mathcal{O}([M, d(f)])$ is defined as the obstruction to making the cells of $d(f)$ pictured in 7.4 globally transversal, keeping the bottom face fixed. We may as well assume that
\( f: M \to M(G_q/PL_q) \) is already PL transversal, so that 7.4 simplifies to

That is, \( d(f) \) is already transversal except in the lower left block, and in the lower left block, \( d(f) \) is the homotopy between the Pontrjagin-Thom constructions on the PL normal bundle of \( L \) and the framed normal bundle of \( L' \). Thus

\[
\mathcal{O}(M, d(f)) = S(L' \to L) = \mathcal{O}([M, F]) \in P, \text{ and similarly for } \mathcal{O}_n.
\]

This proves 7.3 and completes the proof of Theorem 7.1.

**Remark 7.5.** If one follows to the letter the prescription of §2 for computing \( \mathcal{O}([M, d(f)]) \in P \), one actually gets \( \mathcal{O}([M, d(f)]) = S(L' \cup (-L) \to L \cup (-L)) \). Of course, this is the same as \( S(L' \to L) \).

**Remark 7.6.** We leave for the reader the details of the argument for \( G/TOP \). It is only necessary to carry through the “crossing with \( CP(2) \)” construction used in the definition of \( l_{TOP}: MSTOP_q \to WSG_q \).

**Remark 7.7.** The results 7.2 and 6.2 suggest that the map \( \tilde{\mathcal{X}} \times \tilde{\mathcal{Y}}: BSG \to \prod_{n \geq 1} K(Z/2, 4n - 1) \times K(Z_{(2)}, 4n + 1) \) is in some sense equivalent to the natural map \( B\pi: BSG \to B(G/TOP)_{(2)} \). That is, we have identified the fibre of \( \tilde{\mathcal{X}} \times \tilde{\mathcal{Y}} \) with \( BSTOP_{(2)} \) (Theorem 6.2) and we have identified \( \Omega(\tilde{\mathcal{X}} \times \tilde{\mathcal{Y}}): SG \to \prod K(Z/2, 4n - 2) \times K(Z_{(2)}, 4n) \) with \( SG \to (G/TOP)_{(2)} \). I. Madsen and R. J. Milgram have proved that \( B(G/TOP)_{(2)} \) is a product of Eilenberg-MacLane spaces, but they have also shown that there does not exist a commutative diagram

\[
\prod K(Z/2, 4n - 1) \times K(Z_{(2)}, 4n + 1) \\
\tilde{\mathcal{X}} \times \tilde{\mathcal{Y}} \quad \alpha \\
BSG_{(2)} \quad B\pi \\
B(G/TOP)_{(2)}
\]
with $\alpha$ a homotopy equivalence.

Chapter III

8. A Hirzebruch index class for PD spaces. In previous sections, we have defined cohomology classes $\widetilde{\tau} \in H^{*+1}(BSG, \mathbb{Z}/2)$ and $\widetilde{\rho} \in H^{*+1}(BSG, \mathbb{Z}(2))$ which are obstructions to Poincaré transversality in the Thom space $MSG$. From Lemma 3.7, it follows trivially that $8\widetilde{\rho} = 0$. Thus, there exist classes $l \in H^{*}(BSG, \mathbb{Z}/8)$ such that $\beta l = \widetilde{\rho}$, where $\beta$ is the Bockstein homomorphism of the coefficient sequence $0 \to \mathbb{Z}(2) \to \mathbb{Z}(2) \to \mathbb{Z}/8 \to 0$.

In this chapter, we will define a specific class $l = 1 + l_1 + l_2 + \cdots \in H^{*}(BSG, \mathbb{Z}/8)$ with $\beta l = \widetilde{\rho}$. Our class $l$ is a kind of Hirzebruch class, which measures the index modulo 8 for PD spaces. Among its properties are the following:

8.1. (i) If $M^{2n}$ is a $\mathbb{Z}/8$ PD space and $\nu: M^{2n} \to BSG$ classifies the stable fibration of $M^{2n}$, then

$$\langle \nu^*(l), [M^{2n}] \rangle = \text{index}(M^{2n}) \in \mathbb{Z}/8.$$  

(ii) $\rho_1(l) = V^2 \in H^2(BSG, \mathbb{Z}/2)$.

(iii) $l$ satisfies the Whitney sum formula $l(\xi \times \eta) = l(\xi) \otimes l(\eta) + i(VS^qV(\xi) \otimes \widetilde{\tau}(\eta) + \widetilde{\tau}(\xi) \otimes VS^qV(\eta))$, where $i: H^*(, \mathbb{Z}/2) \to H^*(, \mathbb{Z}/8)$ is induced by the inclusion $i: \mathbb{Z}/2 \to \mathbb{Z}/8$.

(iv) $\beta l = \widetilde{\rho} \in H^{*+1}(BSG, \mathbb{Z}(2))$.

(v) $\pi^*(l) = \rho_8(L) \in H^*(BSTOP, \mathbb{Z}/8)$, where $\pi: BSTOP \to BSG$ is the natural map and $L \in H^*(BSTOP, \mathbb{Z}(2))$ is the topological $L$-class of [15].

(vi) $\rho_4(l) \in H^4(BSG, \mathbb{Z}/4)$ is the $\mathbb{Z}/4$ index class constructed in [6]. In particular, $\rho_4(l) = \mathcal{Q}(w_2) + j\sigma_1(w_2w_4, \cdots, w_4)$, where $\mathcal{Q}$ is the Pontrjagin square, $j: H^*(BSG, \mathbb{Z}/2) \to H^*(BSG, \mathbb{Z}/4)$ is the natural map, and $\sigma_1$ is a polynomial in Stiefel-Whitney classes.

It is not difficult to show that properties 8.1(i), (ii), and (iii) characterize $l$ uniquely. The existence of a $\mathbb{Z}/8$ class satisfying 8.1(i) was shown by D. Frank, using the same theory of N. Levitt that we have exploited in this paper. The existence of a $\mathbb{Z}/8$ class satisfying 8.1(ii) has been known for some time, as it is easy to compute homotopy-theoretically the obstruction to lifting a square to a $\mathbb{Z}/8$ class. It is surprisingly difficult, however, to construct a single class which satisfies 8.1(i), (ii), and (iii). Property (iii) is particularly interesting for historical reasons, and by analogy with other index classes (the $\mathbb{Z}(2)$-class of [15] and the $\mathbb{Z}/4$ class of [6]). One might
expect the class \( l \) to satisfy the sum formula \( l(\xi \times \eta) = l(\xi) \otimes l(\eta) \). However, we can prove there is no class which satisfies this simpler formula and which also satisfies 8.1(i).

To construct \( l \in H^*(BSG, \mathbb{Z}/8) \), we will define a suitable homomorphism on the smooth bordism of \( MSG \), \( \varphi: \Omega_c(MSG, \mathbb{Z}/8) \to \mathbb{Z}/8 \), and use Proposition A.11 of the Appendix to obtain \( \Phi(l) \in H^*(MSG, \mathbb{Z}/8) \), where \( \Phi: H^*(BSG, \mathbb{Z}/8) \cong H^*(MSG, \mathbb{Z}/8) \) is the Thom isomorphism.

Let

\[ \Omega'_c(MSG, \mathbb{Z}/8) = \text{kernel} (\Omega_c(MSG, \mathbb{Z}/8) \xrightarrow{\delta} \Omega_{c-1}(MSG) \xrightarrow{\pi} \mathbb{Z}/2). \]

We first define \( \varphi': \Omega_c^*(MSG, \mathbb{Z}/8) \to \mathbb{Z}/8 \). Roughly, given \( f: M_{q+4n} \to MSG_q \), let \( g: N_{q+4n} \to MSG_q \) be the associated \( \mathbb{Z}/8 \) PD space. Set \( \varphi'(M, f) = \text{index} (L_{q+4n}) \in \mathbb{Z}/8 \). It is not obvious that \( \varphi' \) is well-defined, since a globally transversal map \( g: N_{q+4n} \to MSG_q \) may be cobordant to 0, but not "globally transversally cobordant to 0." We need a generalization of Lemma 3.6.

**Lemma 8.2.** If \( N_{q+4n} \) is a \( \mathbb{Z}/8 \) manifold, \( g: N_{q+4n} \to MSG_q \) a globally transversal map, with \( K_{4n} = g^{-1}(BSG_q) \), and if \( [N, g] = 0 \in \Omega_{q+4n}(MSG_q, \mathbb{Z}/8) \), then \( \text{index} (K_{4n}) \equiv 0 \pmod{8} \).

**Proof.** The proof is analogous to the proof of Lemma 3.6. There is an isomorphism \( p: \tilde{\Omega}_{q+j}(MSG_q, \mathbb{Z}/8) \to \pi_{3q+j}(MSG_q \wedge MSO_{2q}, \mathbb{Z}/8) \) if \( j < q - 2 \). Elements of \( \pi_{3q+j}(MSG_q \wedge MSO_{2q}, \mathbb{Z}/8) \) are represented by maps \( S_{3q+j}^8 \to MSG_q \wedge MSO_{2q} \), where \( S_{3q+j}^8 \) is the space obtained from \( S_{3q+j}^8 \) by deleting 8 discs, and then identifying the boundary components. \( S_{3q+j}^8 \) is a \( \mathbb{Z}/8 \) manifold, and every \( \mathbb{Z}/8 \) manifold \( N_{q+j} \) embeds in \( S_{3q+j}^8 \) (as \( \mathbb{Z}/8 \) manifolds) with tubular neighborhood the stable normal bundle of \( N_{q+j} \). Such an embedding defines \( p([N, g]) \in \pi_{3q+j}(MSG_q \wedge MSO_{2q}, \mathbb{Z}/8) \). In particular, if \( g: N_{q+4n} \to MSG_q \) is globally transversal, \( \alpha = p([N, g]): S_{3q+4n}^8 \to MSG_q \wedge MSO_{2q} \) is globally transversal; in fact, \( g^{-1}(BSG_q) = K_{4n} \) and \( \alpha^{-1}(BSG_q \times BSO_{2q}) = X_{4n} \) are homotopy equivalent \( \mathbb{Z}/8 \) PD spaces. Thus \( \text{index} (X_{4n}) = \text{index} (K_{4n}) \).

Careful use of the obstruction theory of §1, Chapter I (in particular, Theorem 1.3(3) and Lemma 1.4) implies that we may homotope \( \alpha: S_{3q+4n}^8 \to MSG_q \wedge MSO_{2q} \) to a strongly transversal map \( \beta \), with \( \beta^{-1}(BSG_q \times BSO_{2q}) = Y_{4n} \subset X_{4n} \), a degree one normal map of \( \mathbb{Z}/8 \) manifolds, which is homotopy equivalence on the Bockstein \( \delta Y \subset \delta X \). Thus \( \text{index} (Y_{4n}) \equiv \text{index} (X_{4n}) \pmod{8} \).

On the other hand, another application of the obstruction theory implies that the \( \mathbb{Z}/8 \) PD space \( Y_{4n} \), obtained from the strongly
transversal map $\beta$, is determined by homotopy class of $\beta: S^{q+4n} \to MSG_q \wedge MSG_{2q}$, modulo cobordism of $Z/8$ PD spaces and connected sum with the Milnor manifold $M^m$ of index 8. The lemma follows.

Now, $s\delta: \Omega_q(MSG, Z/8) \to Z/2$ is nonzero for all $n > 0$. In fact, let $K^{q+4} = S^{q+3} \times I(x, 0) \equiv (-x, 1)$ be the $q + 4$-dimensional Klein bottle. $K^{q+4}$ is a $Z/2$ manifold with $\delta K^{q+4} = S^{q+3}$. In Chapter IV, §10, we will show that there exists a map $\alpha: K^{q+4} \to MSG_q$, with:

$$(8.3) \quad (i) \quad s\delta[K^{q+4}, \alpha] = s[S^{q+3}, \alpha]|_{S^{q+3}} = 1 \in Z/2 \quad \text{and}$$

$$(ii) \quad \langle \alpha^*(\Phi(V_\delta)), [K^{q+4}] \rangle = 0 \in Z/2.$$ 

By Lemma 3.1(iii), $s\delta([K^{q+4}, \alpha][CP(2(n - 1))]) = 1 \in Z/2$. Thus, on $\Omega_{q+4n}(MSG_q, Z/8)$, $s\delta$ is nonzero on $i[K^{q+4}, \alpha][CP(2(n - 1))]$, where $i: \Omega_q(M, Z/2) \to \Omega_{q+4n}(MSG, Z/8)$.

Define $r: \Omega_{q+4n}(MSG, Z/8) \to \Omega_{q+4n}(MSG, Z/8)$ by

$$r([M, f]) = [M, f] - i((s\delta[M, f])[K^{q+4}, \alpha][CP(2(n - 1))]).$$

where the coefficient $(s\delta[M, f])$ is 0 or 1. As the difference of two homomorphisms, $r$ is certainly a homomorphism. We then define

$$\varphi'' = \varphi' \circ r: \Omega_q(MSG, Z/8) \to Z/8.$$ 

It turns out that $\varphi''$ does not quite satisfy the product formulae of Proposition A.11. We need a correction term on products of the form $[P^{q+4n-1}, g][Q^{4b+1}] \in \Omega_{q+4(a+b)}(MSG_q, Z/8)$. So we finally define $\varphi: \Omega_q(MSG, Z/8) \to Z/8$ by

$$\varphi[M, f] = \varphi''[M, f] - i(VS q^1 V(M) \cdot f^*(\widetilde{\kappa}), [M]) \in Z/8,$$

where $\widetilde{\kappa} \in H^{q-1}(BSG, Z/2)$ is the class of §5 and $i: Z/2 \to Z/8$ is the inclusion. In dimensions $\not\equiv 0 \pmod{4}$, we set $\varphi = 0$.

**Theorem 8.4.** (i) $\varphi([M, f][N]) = \varphi[M, f] \cdot \text{index}(N) \in Z/8$ if $[M, f] \in \Omega_q(MSG, Z/8)$ and $[N] \in \Omega_q(pt)$.

(ii) $\varphi(i[\tilde{M}, \tilde{f}][\tilde{N}]) = \varphi(i[\tilde{M}, \tilde{f}]) \cdot \text{index}(\tilde{N}) \in Z/2 \subset Z/8$ if $[\tilde{M}, \tilde{f}] \in \Omega_q(MSG, Z/2)$ and $[\tilde{N}] \in \Omega_q(pt, Z/2)$.

(iii) $\varphi(\rho_0[\tilde{P}, \tilde{F}][\tilde{Q}]) = \varphi(\rho_0[\tilde{P}, \tilde{F}]) \cdot \text{index}(\tilde{Q}) \in Z/2 \subset Z/8$ if $[\tilde{P}, \tilde{F}] \in \Omega_q(MSG, Z/2)$ and $[\tilde{Q}] \in \Omega_q(pt, Z/2)$.

Before proving 8.4, we establish the main results of this section. From 8.4 and Proposition A.11, of the Appendix, we have

**Theorem 8.5.** There is a unique class $l = 1 + l_1 + l_2 + \cdots, l_i \in H^i(BSG, Z/8)$, such that, for any map $f: M \to MSG, M$ a smooth $Z/8$ manifold,
\[ \varphi'(r[M, f]) = \langle L(M) \cdot f^*(\Phi(l)), [M] \rangle + i \langle VSq V(M) \cdot f^*(\tilde{\mathcal{F}}), [M] \rangle \in \mathbb{Z}/8. \]

We next establish properties 8.1(i), (ii), and (iv) for the class \( l \).

**Proof of 8.1.** (i) Let \( S_{8}^{q+4n} \) be the \( \mathbb{Z}/8 \) manifold defined in the proof of Lemma 8.2. If \( M^{4n} \) is a \( \mathbb{Z}/8 \) PD space, \( q \geq 4n \), we may embed \( M^{4n} \subset S_{8}^{q+4n} \) as \( \mathbb{Z}/8 \) PD spaces, so that the normal bundle \( M^{4n} \) in \( S_{8}^{q+4n} \) is the stable normal fibration \( v \) of \( M^{4n} \). The Prongtrjagin-Thom construction then gives a globally transversal \( \mathbb{Z}/8 \) bordism element, \( p: S_{8}^{q+4n} \to MSG_q \), with \( p^{-1}(BSG_q) = M^{4n} \) and \( p |_M = v: M \to BSG_q \). Then, by the definitions of \( \varphi' \) and \( r \), and by 8.5,

\[
\text{index}(M^{4n}) = \varphi'[S_{8}^{q+4n}, P] = \varphi'r[S_{8}^{q+4n}, P] = \langle p^*(\Phi(l)), [S_{8}^{q+4n}] \rangle = \langle (p |_M)^*(l), [M^{4n}] \rangle = \langle \varphi^*(l), [M^{4n}] \rangle \in \mathbb{Z}/8,
\]

since \( L(S_{8}^{q+4n}) = 1 \) and \( VSq^V(S_{8}^{q+4n}) = 0 \).

**Proof of 8.1.** (ii) Let \([N, g] \in \Omega_*(MSG, \mathbb{Z}/2)\). We will prove, without using 8.4, that

\[ \varphi i([N, g]) = i \langle L(N) \cdot g^*\Phi(V^*), [N] \rangle \in \mathbb{Z}/2 \subset \mathbb{Z}/8. \]

On the other hand, it is obvious from 8.5 that

\[ \varphi i([N, g]) = i \langle L(N) \cdot g^*\Phi(\rho l), [N] \rangle \in \mathbb{Z}/2 \subset \mathbb{Z}/8. \]

(That is to say, in the language of Proposition A.11, or A.3, the graded class \( \Phi(\rho l) \in H^*(MSG, \mathbb{Z}/2) \) corresponds to the homomorphism \( \varphi i: \Omega_*(MSG, \mathbb{Z}/2) \to \mathbb{Z}/2 \subset \mathbb{Z}/8 \).) It follows immediately that \( \rho l = V^* \).

To prove 8.6, let \( \Omega'_*(MSG, \mathbb{Z}/2) = \ker (s\delta: \Omega_*(MSG, \mathbb{Z}/2) \to \Omega_{*+1}(MSG) \to \mathbb{Z}/2) \). There is a commutative diagram

\[
\Omega_*(MSG, \mathbb{Z}/2) \xrightarrow{i} \Omega_*(MSG, \mathbb{Z}/8) \\
\downarrow r_2 \quad \quad \quad \quad \downarrow r \\
\Omega'_*(MSG, \mathbb{Z}/2) \xrightarrow{i} \Omega'_*(MSG, \mathbb{Z}/8) \\
\downarrow \varphi' _2 \quad \quad \quad \quad \downarrow \varphi' \\
\mathbb{Z}/2 \xrightarrow{i} \mathbb{Z}/8
\]

where \( r_2[M^{q+4n}, f] = [M^{q+4n}, f] - (s\delta[M, f])[K^{q+4}, c][CP(2n - 2)] \), and where, if \( g: N^{q+4n} \to MSG_q \) is a globally transversal \( \mathbb{Z}/2 \) manifold,
\( \varphi_\delta[N, g] = \text{index} (g^{-1}(\text{BSG}_g)) \in \mathbb{Z}/2. \) (The fact \( \varphi'_\delta(\text{MSG}, \mathbb{Z}/8) \to \mathbb{Z}/8 \) is well-defined implies \( \varphi'_\delta(\text{MSG}, \mathbb{Z}/2) \to \mathbb{Z}/2 \) is well-defined.) From well-known properties of \( V^2 \) and \( L \) (namely: (a) \( V^2 \) is multiplicative, (b) \( \langle \nu^*(V^2), [M^{2n}] \rangle = \text{index} (M^{2n}) \in \mathbb{Z}/2 \) if \( \nu: M^{2n} \to \text{BSG} \) is the normal bundle of a \( \mathbb{Z}/2 \) PD space \( M^{2n} \), and (c) \( \rho_\delta(L(N)) = V^2(N) \) for smooth manifolds \( N \), it is easy to see that

\[
\varphi_\delta[N, g] = \text{index} (g^{-1}(\text{BSG}_g)) \\
= \langle V^2(N) \cdot g^*\Phi(V^2), [N] \rangle \\
= \langle L(N) \cdot g^*\Phi(V^2), [N] \rangle \in \mathbb{Z}/2.
\]

If \( f: M^{4n+4} \to \text{MSG}_p \) is any \( \mathbb{Z}/2 \) bordism element, we then have

\[
\varphi'_\delta\rho_\delta[M, f] = \varphi'_\delta([M, f]) - (s\delta[M, f])[K^{4n+4}, \alpha][\text{CP}(2n - 2)] \\
= \langle L(M)f^*\Phi(V^2), [M] \rangle - (s\delta[M, f])\langle L(K^{4n+4} \times \text{CP}(2n - 2)) \\
\cdot (\alpha^*(\Phi(V^2)) \otimes 1), [K^{4n+4} \times \text{CP}(2n - 2)] \rangle \\
= L\langle (M) \cdot f^*\Phi(V^2), [M] \rangle.
\]

The first equality is the definition of \( r_\delta \), the second equality is 8.7, and the third equality follows from 8.3(ii) and the fact that \( L(K^{4n+4}) = 1 \).

Finally, it is obvious that on elements \( [M, f] \in i(\varphi'_\delta(\text{MSG}, \mathbb{Z}/2)) \subset \Omega_{\nu}(\text{MSG}, \mathbb{Z}/8) \), the error term in the definition of \( \varphi \) vanishes; that is, \( i\langle \text{VSq}^1V(M) \cdot f^*(\widetilde{\tau}), [M] \rangle = 0. \) Thus we have proved 8.6:

\[
\varphi_i[N, g] = \varphi'_i[N, g] = i\varphi'_\delta[N, g] \\
= i\langle L(N) \cdot g^*\Phi(V^2), [N] \rangle \in \mathbb{Z}/2 \subset \mathbb{Z}/8.
\]

**Proof of** 8.1. (iv) We will prove, without using 8.4, that the homomorphisms

\[
\Omega_{\nu+1}(\text{MSG}, \mathbb{Z}/2^s) \xrightarrow{\delta} \Omega_\nu(\text{MSG}) \xrightarrow{\varphi_\delta} \mathbb{Z}/8,
\]

with image interpreted in \( \mathbb{Z}/2^s, s \geq 1 \), are exactly the defining homomorphisms for the class \( \Phi(\widetilde{\tau}) \in H^{n+1}(\text{MSG}, \mathbb{Z}/2) \) (see the Appendix, A.6 and A.7); that is, if \( [M, f] \in \Omega_{\nu}(\text{MSG}, \mathbb{Z}/2^s) \), we will prove that

\[
\varphi_\nu\delta[M, f] = s_{\nu'}([M, f]) - i\langle \text{VSq}^1V(\delta M) \cdot (f|_{S^M})^*(\widetilde{\tau}), [\delta M] \rangle \in \mathbb{Z}/2^s,
\]

where \( i: \mathbb{Z}/2 \to \mathbb{Z}/2^s \). It follows immediately, as in A.13 of the Appendix, that \( \beta l = \tau \).

We obviously have \( \rho_\delta\Omega_{\nu}(\text{MSG}) \subset \Omega_{\nu}(\text{MSG}, \mathbb{Z}/8) \), because \( \delta\rho_\delta \equiv 0 \), hence \( s\delta\rho_\delta \equiv 0 \). Thus \( \varphi''_\nu\delta = \varphi'_\delta; \Omega_{\nu}(\text{MSG}) \to \mathbb{Z}/8 \), hence \( \varphi_\nu\delta: \Omega_{4n+1}(\text{MSG}, \mathbb{Z}/2^s) \to \mathbb{Z}/8 \) is computed as follows. Given \( f: M^{4n+1} \to \text{MSG}_s \), a \( \mathbb{Z}/2^s \) bordism element, assume (after a cobordism) that \( f|_{S^M} \) is globally transversal with \( f^{-1}(\text{BSG}_g) = L^s \subset \delta M \). Then
\[ \varphi \rho \delta [M, f] = \text{index } (L^{*}) - i \langle V S q^{i} V (\delta M) \cdot (f \mid_{\delta M})^{*} (\tilde{\xi}), [\delta M] \rangle \in \mathbb{Z}/8. \]

Of course, we interpret this number in \( \mathbb{Z}/2^{*} \). By Chapter I, Lemma 3.7, and 5.4(ii) of Chapter II, this exactly the homomorphism

\[ \Omega_{*+1}(\text{MSG}, \mathbb{Z}/2^{*}) \rightarrow \mathbb{Z}/2^{*} \]

which defines \( \Phi(\tilde{\xi}) \in H^{*+1}(\text{MSG}, \mathbb{Z}/2) \), as desired.

The proof of 8.1(iii) is rather difficult, and will be discussed in §9. The property 8.1(v) of our class \( l \) follows easily from 8.1(i), (ii), and (iii), and the the discussion in [15] where characterizing properties of \( \rho(l) \in H^{*}(\text{BSTOP}, \mathbb{Z}/8) \) are listed.

**Proof of 8.1.** (vi) From the definition of \( \varphi: \Omega_{*}(\text{MSG}, \mathbb{Z}/8) \rightarrow \mathbb{Z}/8 \) and Theorem 8.5, we see that, if \( f: M^{*+4n} \rightarrow \text{MSG} \) is a globally transversal \( \mathbb{Z}/4 \) manifold, with \( L^{*n} = f^{-1}(\text{BSG}) \subset M^{*+4n} \), then

(a) \[ \text{index } (L^{*n}) = \langle L(M) \cdot f^{*} \Phi(l), [M] \rangle \in \mathbb{Z}/4. \]

Also from 8.1(ii),

(b) \[ \rho_{*} \rho_{*}(l) = V^{*} \in H^{*}(\text{BSG}, \mathbb{Z}/2). \]

Since any \( \mathbb{Z}/4 \) manifold \( f: M^{*+4n} \rightarrow \text{MSG} \) can be made transversal by subtracting \( j([K^{*+4}, \alpha] [CP(2n - 2)]) \) if necessary, \( j: \Omega_{*}(, \mathbb{Z}/2) \rightarrow \Omega_{*}(, \mathbb{Z}/4) \), we see that these two properties (a), (b) uniquely characterize \( \rho_{*}(l) \). But the \( \mathbb{Z}/4 \) index class of [6] also has these properties, hence 8.1(vi) follows.

We return now to the proof of Theorem 8.4.

**Proof of 8.4.** (ii) We have already shown in 8.6 that, for any \( \mathbb{Z}/2 \) bordism element \( g: N \rightarrow \text{MSG} \),

\[ \varphi i([N, g]) = i \langle L(N) \cdot g^{*} \Phi(V^{*}), [N] \rangle = i \langle V^{*}(N) \cdot g^{*} \Phi(V^{*}), [N] \rangle \in \mathbb{Z}/2 \subset \mathbb{Z}/8. \]

8.4(ii) is an easy consequence of this and the multiplicativity of \( V^{*} \).

**Proof of 8.4.** (iii) We have already shown in the proof of 8.1(iv) that \( \varphi \rho \delta: \Omega_{*}(\text{MSG}, \mathbb{Z}/2) \rightarrow \mathbb{Z} \) is the homomorphism on a \( \mathbb{Z}/2 \) bordism which corresponds to the cohomology class \( \rho_{*} \Phi(\tilde{\xi}) \in H^{*+1}(\text{MSG}, \mathbb{Z}/2) \) (see Propositions A.3 and A.6 of the Appendix). In particular, \( \varphi \rho \delta \) is multiplicative with respect to the index, which proves 8.4(iii).

**Proof of 8.4.** (i) We have four cases, depending on the dimension of \( N \), namely, \( \text{dim } (N) \equiv 0, 1, 2, 3 \mod 4 \). We denote these cases 0, 1, 2, and 3, respectively.
Case 0. We are given a $\mathbb{Z}/8$ bordism element $f: M^{q+4a} \to MSG_q$ and a closed manifold $N^{4b}$. By definition of $\varphi$,

$$
\varphi([M, f][N]) = \varphi''([M, f][N]) - i \langle V^q \cdot \Phi(\widetilde{\beta}) \otimes 1 \rangle, [M \times N] > 
$$

Thus it suffices to prove $\varphi''([M, f][N]) = \varphi''([M, f]) \cdot \text{index } (N) \in \mathbb{Z}/8$, since then

$$
\varphi([M, f][N]) = \varphi''([M, f][N]) - i \langle V^q \cdot \Phi(\widetilde{\beta}) \otimes 1 \rangle, [M] < V(N), [N] > .
$$

Suppose $[M, f] \in \Omega''(MSG, \mathbb{Z}/8) = \ker (s\delta: \Omega''(MSG, \mathbb{Z}/8) \to \mathbb{Z}/2)$. Then we may assume that $f: M^{q+4a} \to MSG_q$ is globally transversal, with $f^{-1}(BSG_q) = L^{4a} \subset M^{q+4a}$. By definition of $\varphi''$,

$$
\varphi''([M, f][N]) = \varphi''([M, f]) \cdot \text{index } (L^{4a}) \in \mathbb{Z}/8.
$$

Moreover, it is obvious that $f_\pi: M^{q+4a} \times N^{4b} \to MSG_q$ if globally transversal, with $(f_\pi)^{-1}(BSG_q) = L^{4a} \times N^{4b}$. Necessarily,

$$
\delta(M^{q+4a}, f)[N^{4b}] = 0
$$

and, thus,

$$
\varphi''([M^{q+4a}, f][N^{4b}]) = \varphi'([M^{q+4a}, f][N^{4b}])
= \text{index } (L^{4a} \times N^{4b})
= \text{index } (L^{4a}) \cdot \text{index } (N^{4b})
= \varphi''[M, f][\text{index } (N)] ,
$$

as desired.

Finally, by linearity of $\varphi$, it suffices to check the case $[M, f] = i([K^{q+4}, \alpha][CP(2a - 2)])$. But we have already shown in 8.6 that

$$
\varphi i([K^{q+4}, \alpha][CP(2a - 2)])
= i \langle L(K^{q+4} \times CP(2a - 2)) \cdot (\alpha^* \Phi(V^q) \otimes 1) \rangle,
[K^{q+4} \times CP(2a - 2)] > = 0
$$

by 8.3(ii) and the fact $L(K^{q+4}) = 1$ (this is also obvious from the definition of $\varphi$), and we have shown that

$$
\varphi i([K^{q+4}, \alpha][CP, \alpha][CP(2a - 2)][N^{4b}])
= i \langle (K^{q+4} \times CP(2a - 2) \times N^{4b}) \cdot (\alpha^* \Phi(V^q) \otimes 1 \otimes 1), [K^{q+4} \times CP(2a - 2) \times N^{4b}] >
= 0
$$
by 8.3(ii) and the fact \( L(K^{i+r}) = 1 \). This proves Case 0 of 8.4(i).

In all three cases below, it is easy to check that \( s\delta([M, f][N]) = 0 \). Thus,

\[
\varphi([M, f][N]) = \varphi'([M, f][N]) - i\langle VSq^i V(M \times N)(f^*\widetilde{\kappa} \otimes 1), [M \times N] \rangle.
\]

Also, in Cases 1, 2, and 3, index \((N) = 0\), so what we must show is that \( \varphi([M, f][N]) = 0 \).

### Case 2

We have \( f: M^{q+a-2} \to MSG_q \) and \( N^{4b+2} \), where \( M \) is a \( Z/8 \) manifold and \( N \) is closed. For dimensional reason,

\[
\langle VSq^i V(M \times N)(f^*\widetilde{\kappa} \otimes 1), [M \times N] \rangle = 0.
\]

On the other hand, by Theorem 3.4 we may assume that \( f: M \to MSG_q \) is globally transversal, with \( f^{-1}(BSG_q) = L^{4a-2} \subset M^{q+a-2} \). Then \( f\pi_2: M \times N \to MSG_q \) is globally transversal, with \( (f\pi_2)^{-1}(BSG_q) = L^{4a-2} \times N^{4b+2} \). Thus \( \varphi'([M, f][N]) = \text{index}(L^{4a-2} \times N^{4b+2}) = 0 \), which proves Case 2.

### Case 1

We have \( f: M^{q+a-2} \to MSG_q \) and \( N^{4b+1} \). We know from the structure of \( \Omega_*(pt) \) that \( 8[N] = 0 \in \Omega_{4b+1}(pt) \). Thus there is a \( Z/8 \) manifold \( \tilde{N} \) with \( \delta\tilde{N} = N \). We will now use the fact that the composition \( \rho\delta \) behaves like a derivation. Thus

\[
\rho\delta([M, f][\tilde{N}]) = [M, f][N] + [\delta M, f|_{\delta M}][\tilde{N}] \in \Omega_{q+4(a+b)}(MSG_q, Z/8).
\]

The proof of Case 2 above show that \( \varphi([\delta M, f][\tilde{N}]) = 0 \). Thus, by the proof of 8.1(iv),

\[
\varphi([M, f][N]) = \varphi\rho\delta([M, f][\tilde{N}])
\]

\[
= s_0([M, f][\tilde{N}]) - i\langle VSq^i V(\delta(M \times \tilde{N}))(f^*\widetilde{\kappa} \otimes 1), [\delta(M \times \tilde{N})] \rangle
\]

\[
= i(s_0[M, f] \cdot d(\delta\tilde{N})) - \langle V^q(M) \cdot f^*\widetilde{\kappa}, [M] \rangle \langle VSq^i V(\delta\tilde{N}), [\delta\tilde{N}] \rangle
\]

\[
= 0.
\]

This proves Case 1.

### Case 3

We have \( f: M^{q+a-1} \to MSG_q \) and \( N^{4b-1} \). As in Case 1, we can find a \( Z/8 \) manifold \( \tilde{N} \), with \( \delta\tilde{N} = N \). Then \( \rho\delta([M, f][\tilde{N}]) = [M, f][N] + [\delta M, f|_{\delta M}][\tilde{N}] \), hence

\[
\varphi([M, f][N]) = \varphi\rho\delta([M, f][\tilde{N}]) - \varphi([\delta M, f|_{\delta M}][\tilde{N}])
\]

\[
= \varphi\rho\delta[M, f] \cdot \text{index}(\tilde{N}) - \varphi\rho\delta[\delta M, f|_{\delta M}] \cdot \text{index}(\tilde{N})
\]

\[
= 0.
\]
The second equality uses both the proof of 8.4(iii), which implies that \( \varphi \circ \partial \) is multiplicative with respect to the index, and the proofs of 8.4(ii) and Case 0 of 8.4(i) above, which imply that \( \varphi([\tilde{M}^{q+i}, \tilde{f}][\tilde{N}^4]) = \varphi(\tilde{M}^{q+i}, \tilde{f}) \cdot \text{index}(\tilde{N}^4) \), for any \( \mathbb{Z}/8 \) manifolds \( \tilde{M}^{q+i} \) and \( \tilde{N}^4 \). This proves Case 3, and completes the proof of Theorem 8.4.

**Remark 8.8.** The definition of \( \varphi: \Omega_{\ast}(\text{MSG}, \mathbb{Z}/8) \to \mathbb{Z}/8 \) can be extended directly to PL-bordism, \( \varphi: \Omega_{\ast}^{\text{PL}}(\text{MSG}, \mathbb{Z}/8) \to \mathbb{Z}/8 \). Moreover, the formula of Theorem 8.5 is true for \( M \) any PL \( \mathbb{Z}/8 \) manifold. This assertion does not follow from the product formulae 8.4, however. One needs the more delicate formulae

\[
\varphi(i([\tilde{M}, \tilde{f}][\tilde{N}])) = \varphi(i[\tilde{M}, \tilde{f}]) \cdot \text{index}(\tilde{N}) \in \mathbb{Z}/2^r \subset \mathbb{Z}/8
\]

and

\[
\varphi(\rho \circ \partial([\tilde{P}, \tilde{f}][\tilde{Q}])) = \varphi(\rho \circ \partial[\tilde{P}, \tilde{f}]) \cdot \text{index}(\tilde{Q}) \in \mathbb{Z}/2^r \subset \mathbb{Z}/8,
\]

where \( \tilde{M}, \tilde{N}, \tilde{P}, \tilde{Q} \) are \( \mathbb{Z}/2^r \) manifolds, \( r \leq 3 \), \( \dim(\tilde{M} \times \tilde{N}) \equiv 0 \pmod{4} \) and \( \dim(\tilde{P} \times \tilde{Q}) \equiv 1 \pmod{4} \). The reason we need stronger formulae to deduce 8.5 for PL-manifolds is that \( \Omega_{\ast}^{\text{PL}}(pt, \mathbb{Z}/8) \) is not generated by oriented manifolds and \( \mathbb{Z}/2 \) manifolds. (See the Appendix, Remark A.14.) In the next section, we will establish generalizations of these more difficult product formulae, which will thus prove 8.5 for PL-manifolds.

9. The Whitney sum formula for the class \( l \). In this section, we will establish Property 8.1(iii) of the class \( l \in H^\ast(B\text{SG}, \mathbb{Z}/8) \). That is, if \( \xi \) and \( \eta \) are two oriented spherical fibrations, we prove

\[
l(\xi \times \eta) = l(\xi) \otimes l(\eta) + i(VSQ^1 V(\xi) \otimes \tilde{\mathcal{K}}(\eta))
\]

\[+ \tilde{\mathcal{K}}(\xi) \otimes VSQ^1 V(\eta)) \in H^\ast(B\xi \times B\eta, \mathbb{Z}/8),
\]

where

\[
i: H^\ast(\cdot, \mathbb{Z}/2) \longrightarrow H^\ast(\cdot, \mathbb{Z}/8).
\]

To establish 9.1, we need the Whitney sum formula for the class \( \tilde{\mathcal{K}} \in H^{\ast-1}(B\text{SG}, \mathbb{Z}/2) \).

\[
\tilde{\mathcal{K}}(\xi \times \eta) = \tilde{\mathcal{K}}(\xi) \otimes V^2(\eta)
\]

\[+ V^2(\xi) \otimes \tilde{\mathcal{K}}(\eta) \in H^{\ast-1}(B\xi \times B\eta, \mathbb{Z}/2).
\]

9.2 will be proved in §10 by giving a homotopy theoretic definition of the class \( \tilde{\mathcal{K}} \) in terms of functional cohomology operations, and then proving a product formula for the relevant functional operations. A proof of 9.2 could also be given by reducing 9.2 to
known formula for the Kervaire surgery obstruction.

As a first step in the proof of 9.1, we describe generators of $H_*(X \times Y, \mathbb{Z}/2^r)$.

**Lemma 9.3.** $H_*(X \times Y, \mathbb{Z}/2^r)$ is generated by the Hurewicz image of

(i) "products" $j([M, f][N, g])$, where $M$ and $N$ are $\mathbb{Z}/2^r$-manifolds, $s \leq r$, $f: M \to X$, $g: N \to Y$, and $j: \Omega_*(\mathbb{Z}/2^r) \to \Omega_*(\mathbb{Z}/2^r)$, and

(ii) Bocksteins of products $\rho_s \delta([P, f][Q, g])$, where $P$ and $Q$ are $\mathbb{Z}/2^r$-manifolds, $s < r$, $f: P \to X$, and $g: Q \to Y$.

Note in (ii) that, if

$s \geq r$, $\rho_s \delta([P, f][Q, g]) = \rho_{s-r}\delta([P, f]\cdot\rho_r(Q, g)] + \rho_s([P, f] \cdot \rho_s(Q, g])$.

A simple proof of Lemma 9.3 can be given by studying tensor products of elementary chain complexes

$$(0 \to \mathbb{Z} \to \mathbb{Z} \to 0) \otimes (0 \to \mathbb{Z} \to \mathbb{Z} \to 0),$$

since by a classical "standard basis theorem" such complexes account for the 2-torsion in $H_*(X, \mathbb{Z})$ and $H_*(Y, \mathbb{Z})$. We leave the details to the reader.

To prove 9.1, it clearly suffices to prove

$$\phi(l(\xi \times \eta)) = \phi(\sum_{a} l_{a}(\xi \times \eta))$$

for all $\mathbb{Z}/2^r$-manifolds $h: X \to T_\xi \wedge T_\eta$. By induction on $n$, where $l = \sum_{a \geq 0} l_{a}$, 9.4 follows if we show

$$\phi_{l}(X, h) = \langle L(X) \cdot h^* \phi(l(\xi \times \eta)) \rangle, [X] \rangle \in \mathbb{Z}/2^r$$

for all $\mathbb{Z}/2^r$-manifolds $h: X \to T_\xi \wedge T_\eta$. By induction on $n$, where $l = \sum_{a \geq 0} l_{a}$, 9.4 follows if we show

$$\phi_{l}(X, h) = \langle L(X) \cdot h^* \phi(l(\xi \times \eta)) \rangle, [X] \rangle$$

for $[X, h] = j([M, f][N, g])$ and for $[X, h] = \rho_s([P, f][Q, g])$, $M, N, P, Q$
as above, $4: Z/2 \rightarrow Z/8$.

We first dispose of cases $[X, h] = j([M, f][N, g])$, where $M$ and $N$ are $Z/2$- or $Z/4$-manifolds. The second term on the RHS of (9.5) vanishes. Thus we must show
\[
\langle L(M \times N)(f \times g)*\Phi(\rho_2 l(\xi \times \eta)), [M \times N] \rangle = \langle L(M \times N)(f \times g)*\Phi(\rho_2 l(\eta) \otimes \rho_2 l(\eta)), [M \times N] \rangle \in Z/2^s, \quad s = 1, 2.
\]

But we know $\rho_2 l(\xi \times \eta) = \rho_2 l(\xi) \otimes \rho_2 l(\eta)$, since, by 8.1(ii), $\rho_2(l) = V^s$. Also, we know that $\rho_2 l(\xi \times \eta) = \rho_2 l(\xi) \otimes \rho_2 l(\eta)$, since, by 8.1(vi), $\rho_2(l)$ is the $Z/4$-index class defined in [6].

We will now specialize to $T\xi = T\eta = MSG$. By naturality of the class $l$, this is sufficient. We write $f: M^a \rightarrow MSG$ instead of $f: M^{q-a} \rightarrow MSG$. Of course, we work in the stable range, $a < q - 2$. There should be no confusion if we write $L^a = f^{-1}(BSG) \subset M^a$, when $f: M^a \rightarrow MSG$ is globally transversal.

We are left with five cases in 9.5:

**Case 1.** $[X, h] = [M^{4a+2}, f][N^{4b+2}, g], M, N Z/8$-manifolds.

**Case 2.** $[X, h] = [M^{4a}, f][N^{4b}, g], M, N Z/8$-manifolds.

**Case 3.** $[X, h] = [M^{4a+1}, f][N^{4b-1}, g], M, N Z/8$-manifolds.

**Case 4.** $[X, h] = \rho_2 l(P^{4a+2}, f)[Q^{4b-1}, g]), P, Q Z/2$- or $Z/4$-manifolds.

**Case 5.** $[X, h] = \rho_2 l([P^{4a+1}, f][Q^{4b}, g]), P, Q Z/2$- or $Z/4$-manifolds.

We will concentrate on evaluating the RHS of 9.5, $\phi([X, h])$, in these five cases, and leave to the reader the algebraic computation of the RHS of 9.5.

**Proof of Case 1.** Recall from §8 the definition of
\[
\phi: \widetilde{O}_v(MSG, Z/8) \rightarrow Z/8.
\]

If $f: X^{4n} \rightarrow MSG$ is globally transversal, $X$ a $Z/8$-manifold, with $Y^{4n} = h^{-1}(BSG) \subset X$, then
\[
(9.6) \quad \phi([X, h]) = \text{index } (Y^{4n}) - 4 \langle V\text{Sq}^v V(X) \cdot h^* \Phi(K), [X] \rangle \in Z/8.
\]

In Case 1, $[X, h] = [M^{4a+2}, f][N^{4b+2}, g]$. We may assume that both $f: M^{4a+2} \rightarrow MSG$ and $g: N^{4b+2} \rightarrow MSG$ are globally transversal, since there is no obstruction in this dimension. Let $K^{4a+2} = f^{-1}(BSG) \subset M$, $L^{4b+2} = g^{-1}(BSG) \subset N$. Then $f \times g: M \times N \rightarrow MSG \land MSG$ is globally
transversal, and $(f \times g)^{-1}(BSG \times BSG) = K \times L$. Moreover, by 9.6 and 9.2, and since

\[
V_Sq^i V(M \times N) = V^i(M) \otimes V_Sq^i(N) + V_Sq^i V(M) \otimes V^i(N),
\]

\[
\phi(M^{a+2}, f)[N^{a+2}, g])
\]

= index $(K \times L) - 4\langle V_Sq^i V(M \times N) \cdot (f \times g)^* \\
\times (\Phi(\mathcal{H} \otimes V^2 + V^2 \otimes \mathcal{H})), [M \times N]\rangle
\]

= index $(K \times L) = 0$.

The reader can check by dimensional considerations that the RHS of 9.5 also vanishes in Case 1.

**Proof of Case 2.** We first argue that we may assume both $f: M^{a} \rightarrow MSG$ and $g: N^{b} \rightarrow MSG$ are globally transversal. Let $\alpha: K^{4} \rightarrow MSG$ be the nontransversal $Z/2$-manifold used in 8.3. ([K^4, \alpha] will be precisely constructed in §10; this is the step where we use $T_\xi = T_\eta = MSG$.) In any dimension $4\alpha$, we get a nontransversal manifold $\alpha\pi; K^4 \times CP(2\alpha - 2) \rightarrow MSG$. If $f: M^{a} \rightarrow MSG$ is not transversal, write

\[
[M^{a} f][N^{b}, g] = [M', f'][N, g] + j(([K^{4}, \alpha][CP(2\alpha - 2)])(\rho^i[N, g])),
\]

where $[M', f'] = [M, f] - j([K^{4}, \alpha][CP(2\alpha - 2)])$. Since both sides of formula 9.5 are additive in $[X, h]$, this reduces the general Case 2 to the case $[X, h] = [M', f'][N, g]$, where $f': M' \rightarrow MSG$ is transversal. (We have already dealt with the case $[X, h] = j(Z/2$-manifold$).) Similarly, we may assume that $g: N^{b} \rightarrow MSG$ is transversal.

Now, assuming that $f: M^{a} \rightarrow MSG$ and $g: N^{b} \rightarrow MSG$ are transversal, let $K^{a} = f^{-1}(BSG) \subset M$, $L^{b} = g^{-1}(BSG) \subset N$. Then, by 9.6 and 9.2,

\[
\phi([M, f][N, g])
\]

= index $(K \times L) - 4\langle V_Sq^i V(M \times N)(f \times g)^* \\
\times (\Phi(\mathcal{H} \otimes V^2 + V^2 \otimes \mathcal{H}), [M \times N]\rangle
\]

= index $(K \times L) - 4\langle V^i(M) \cdot f^* \Phi(V^2), [M]\rangle\langle V_Sq^i V(N) \cdot g^* \Phi(\mathcal{H}), [N]\rangle \\
- 4\langle V_Sq^i V(M) \cdot f^* \Phi(\mathcal{H}), [M]\rangle\langle V^i(N) \cdot g^* \Phi(V^2), [N]\rangle
\]

= (index $(K) - 4\langle V_Sq^i V(M) \cdot f^* \Phi(\mathcal{H}), [M]\rangle$) \\
\times (index $(L) - 4\langle V_Sq^i V(N) \cdot g^* \Phi(\mathcal{H}), [N]\rangle$)
\]

= $\phi([M^{a}, f]\cdot\phi(N^{b}, g)) \in Z/8$.

(We have used the identities $\langle V^i(M) \cdot f^* \Phi(V^2), [M]\rangle = \langle V^i(K), [K^{a}]\rangle = index (K^{a}) (mod 2)$, and similarly, $\langle V^i(N) \cdot g^* \Phi(V^2), [N]\rangle = index (L^{b}) (mod 2)$.)
It is easy to see that this agrees with the RHS of (9.5).

Case 3 is very difficult, without making use of the results of Cases 4 and 5, so we postpone it until the end of the section.

To study Cases 4 and 5, we recall that, if \( \widehat{h} : X^{4s+1} \rightarrow MSG \) is a \( Z/2^s \)-manifold, then we may always assume \( h \mid _{\delta X} : \delta X \rightarrow MSG \) is globally transversal, with \( Y^{4s} = (\widehat{h} \mid _{\delta X})^{-1}(BSG) \subset \delta X \). If \( [\widehat{X}, \widehat{h}] = [P, f][Q, g] \), then \( \rho_2 \delta[\widehat{X}, \widehat{h}] = \delta[P, f] \rho_2[Q, g] + \rho_4[P, f] \cdot \delta[Q, g] \). The formula 9.6 for \( \phi \rho \delta[P, f][Q, g] \) then becomes (by 9.2)

\[
\phi \rho \delta([P, f][Q, g]) = \text{index } (Y)
\]

For \( \phi \rho \delta([P, f][Q, g]) = \text{index } (Y) \in Z/8 \),

Moreover, we proved in Lemma 3.7 that

\[
2^{s-3} s_2([P, f][Q, g]) = \text{index } (Y) \in Z/8 ,
\]

where \( s_2 : \widehat{O}_{4s+1}(MSG, Z/2^s) \rightarrow Z/2^s \) is the transversality obstruction of §3.

Proof of Case 4. We may assume that \( f : P^{4s+2} \rightarrow MSG \) is globally transversal, with \( K^{4s+2} = f^{-1}(BSG) \subset P, K^{4s+2} \) a \( Z/2^s \)-PD space, \( s = 1 \) or 2. We consider two subcases for products \( [P^{4s+2}, f][Q^{4s-1}, g] \).

Subcase 1. \( g : Q^{4s-1} \rightarrow MSG \) transversal, \( L^{4s-1} = f^{-1}(BSG) \subset Q, L \) and \( Q Z/2^s \)-manifolds.

Subcase 2. \( Q^{4s-1} \) a closed manifold, \( g : Q^{4s-1} \rightarrow MSG \).

Since there is a nontransversal example on a closed manifold, \( \alpha : S^3 \rightarrow MSG \) (e.g., \( [S^3, \alpha] = \delta[K, \alpha] \), where \( [K, \alpha] \) is as in 8.3), we see by linearity that Subcases 1 and 2 suffice.

Subcase 1. In this case, \( f \times g : P^{4s+2} \times Q^{4s-1} \rightarrow MSG \wedge MSG \) is transversal, with \( (f \times g)^{-1}(BSG \times BSG) = K^{4s+2} \times L^{4s-1} \). Since \( 2^s \delta(K^{4s+2} \times L^{4s-1}) \) is a boundary, index \( (\delta(K^{4s+2} \times L^{4s-1})) = 0 \). The hypothesis \( g : Q^{4s-1} \rightarrow MSG \) transversal also implies \( \langle V^s(Q) \cdot g^* \Phi(\widehat{K}), [Q] \rangle = 0 \). We thus conclude from 9.7 that \( \phi \rho \delta([P^{4s+2}, f][Q^{4s-1}, g]) = 0 \).

To evaluate the first term on the RHS of 9.5, it is helpful to use the identity

\[
\langle L(\delta \widehat{X}) \cdot (h \mid _{\delta X})^* \Phi(l(\xi) \otimes l(\eta)), [\delta \widehat{X}] \rangle
\]

where \( \widehat{h} : \widehat{X} \rightarrow T \xi \wedge T \eta \) is a \( Z/2^s \)-manifold, \( s \leq 3 \), and \( \beta : H^*(\,; Z/2) \rightarrow \cdots \).
$H^{*+1}(\omega, Z)$ is the Bockstein. Thus the first term on the RHS of 9.5 vanishes if $[\hat{X}, \hat{h}] = [P^{4a+2}, f][Q^{4b-1}, g]$. The second term is easily calculated, using $\rho_2[\partial P \times Q] = [\partial P] \cdot \rho_1[Q] + \rho_2[\partial P] \cdot [\partial Q]$, and also vanishes in Subcase 1, as desired.

Subcase 2. If $Q$ is closed, $\delta(P^{4a+2} \times Q^{4b-1}) = \partial P \times Q$. If $g: Q^{4b-1} \to MSG$ is not transversal, then the map $f \times g: \partial P \times Q \to MSG \land MSG$ is not transversal, although it is bordant to a globally transversal map. We want to compute index $(Y) \in Z/8$, where $Y = h^{-1}(BSG \times BSG)$, $h: X^{4a+4b} \to MSG \land MSG$ a transversal map bordant to $f \times g: \partial P \times Q \to MSG \land MSG$.

Let $Q^{4b-1} = U_1 \cup U_2$ be a partition of $g: Q^{4b-1} \to MSG$ (see §3). That is, $U_1$ and $U_2$ are codimension 0-submanifolds of $Q$, $g|_{U_1}: U_1 \to MSG$ is globally transversal with respect to the mapping cylinder $M_\gamma \subset MSG$ of the universal bundle $\gamma \to BSG$, and $g|_{U_2}: U_2 \to MSG$ is globally transversal with respect to a smaller mapping cylinder $M_\gamma' \subset M_\gamma$.

\[ L_1 = f^{-1}(M_\gamma) \cap U_1 \]
\[ L_2 = f^{-1}(M_\gamma') \cap U_2 \]

Let $L_i = (g|_{U_i})^{-1}(M_\gamma)$, $L_2 = (g|_{U_2})^{-1}(M_\gamma')$. Then by Lemma 1.4, the inclusion $\partial L_2 \to \partial L_1$ is a degree one normal map of closed, $4b - 2$-dimensional PD spaces. Moreover, the global transversality obstruction $\sigma(Q^{4b-1}, g) \in Z/2$ is equal to the Kervaire obstruction $S(\partial L_2 \to \partial L_1) \in Z/2$.

Since $f|_{U_1}: \partial P \to MSG$ is globally transversal, the partition of $[Q, g]$ induces a partition of $[\partial P \times Q, f \times g]$. Namely,

\[ \delta P \times Q = \delta P \times U_1 \cup \delta P \times U_2 \]

In the intersection, $\delta P \times (U_1 \cap U_2)$, we get a normal map of closed, $4a + 4b - 1$-dimensional PD spaces $\delta K \times \partial L_2 \to \delta K \times \partial L_1$. (Recall $K = f^{-1}(BSG) \subset P^{4a+2}$.) This normal map has associated an invariant $\theta(\delta K \times \partial L_2 \to \delta K \times \partial L_1) \in Z/8$, and, by Lemma 3.11, the index we
need to compute is given by

\[
\text{index}(Y) = \text{index}(\delta K \times L_1) + \text{index}(\delta K \times L_2)
- \theta(\delta K \times \partial L_2 \rightarrow \delta K \times \partial L_1) \in \mathbb{Z}/8.
\]

Of course, \(\text{index}(\delta K \times L_1) = \text{index}(\delta K \times L_2) = 0\). By Lemma 3.12,

\[
\theta(\delta K \times \partial L_2 \rightarrow \delta K \times \partial L_1) = 4d(\delta K) \cdot S(\partial L_2 \rightarrow \partial L_1).
\]

Since

\[
d(\delta K) = \langle V Sq^* V(\delta K) \rangle,
= \langle V^* (\delta P) f^* \Phi(V Sq^* V) + V Sq^* V(\partial P) \cdot f^* \Phi(V^2), [\delta P] \rangle \in \mathbb{Z}/2,
\]

and, since \(S(\partial L_2 \rightarrow \partial L_1) = 2[Q^{s-1}, g] = \langle V^2(Q) \cdot g^* \Phi(\wedge^2), [Q] \rangle \in \mathbb{Z}/2\), we obtain from 9.7

\[
\phi([P^{s+2}, f][Q^{s-1}, g]) = 4\langle V^2(\delta P) \cdot f^* \Phi(V^2), [\delta P] \rangle \langle V^2(Q) \cdot f^* \Phi(\wedge^2), [Q] \rangle.
\]

It is easy to check that this agrees with the RHS of 9.5.

**Proof of Case 5.** We deal separately with the following subcases.

**Subcase 1.** \(P, Q \mathbb{Z}/2^s\)-manifolds, \(s \leq 3\), and \(g: Q^{s} \rightarrow \text{MSG}\) globally transversal.

**Subcase 2.** \(P, Q \mathbb{Z}/2\)-manifolds, \(f: P^{s+1} \rightarrow \text{MSG}\) transversal.

**Subcase 3.** \(P, Q \mathbb{Z}/2\)-manifolds, \([P, f] = [L^s][S^s], [\alpha]\), where \([S^s], [\alpha] = \delta[K^s, \alpha], [K, \alpha]\) as in 8.3, and \(L^s\) is a \(\mathbb{Z}/2\) \(6\)-manifold with \(d(\delta L^s) = 1 \in \mathbb{Z}/2\). Thus \(s_{[P, f]} = d(\delta L^s) \cdot s[S^s, [\alpha]] = 1 \in \mathbb{Z}/2\).

The point is, Subcases 2 and 3 imply Case 5 for all \(\mathbb{Z}/2\)-manifolds \(P\) and \(Q\), by linearity. The fact that the nontransversal example \([L^s][S^s, \alpha]\) has dimension 9 rather than 5 is no drawback since both sides of (9.5) "commute with crossing with \(CP(2)\)." Subcase 1 is then sufficient for all \(\mathbb{Z}/4\) and \(\mathbb{Z}/8\)-manifolds since there is the nontransversal example \([Q, g] = j[K^s, \alpha], j: \mathcal{O}_{s}(\mathbb{Z}/2) \rightarrow \mathcal{O}_{s}(\mathbb{Z}/2^s), s = 2\) or 3, which reduces the nontransversal \(\mathbb{Z}/2^s\)-case to the \(\mathbb{Z}/2\)-case.

**Subcase 1.** Consider \(f: P^{s+1} \rightarrow \text{MSG}\). We may assume that there is a partition \(P^{s+1} = U_1 \cup U_2\) such that \(\partial P \subset U_1\), \(f|_{v_1}: U_1 \rightarrow \text{MSG}\) is globally transversal with respect to the mapping cylinder \(M_r\), and \(f|_{v_2}: U_2 \rightarrow \text{MSG}\) is globally transversal with respect to \(M'_r \subset M_r\).
We may assume that $\partial P \subset U$, roughly because there is no obstruction to transversality on $\partial P$. Let $L_i = f^{-i}(M_i) \cap U_i$, $L_0 = f^{-1}(M') \cap U_0$. We will use the notation $\delta L_i = L_i \cap \partial P$ and $\delta L = L_0 \cap U_2$. Thus the inclusion $\partial L_0 \to \partial L_i$ is a degree one normal map of closed, $4\alpha$-dimensional PD spaces.

We are assuming that $g: Q' \to MSG$ is transversal. Let $K' = g^{-1}(BSG) \subset Q$. Now, $\delta(P \times Q) = \delta P \times Q \cup_{\delta P \times \delta Q} P \times \delta Q$. The partition $P = U_1 \cup U_2$ induces a partition

$$\delta(P \times Q) = (\delta P \times Q \cup_{\delta P \times \delta Q} U_1 \times \delta Q) \cup U_2 \times \delta Q = V_1 \cup V_2.$$ 

In the intersection, $V_1 \cap V_2 = (U_1 \cap U_2) \times \delta Q$, we have the degree one normal map $\partial L_0 \times \delta K \to \partial L_i \times \delta K$. On side $V_1$ of the partition, we have $\partial L_i \times \delta K = \partial(\delta L_i \times K \cup_{\delta P \times \delta Q} L_i \times \delta K)$. On side $V_2$ of the partition, we have $\partial L_0 \times \delta K = \partial(L_0 \times \delta K)$.

We know that $f \times g|_{\partial P} : \delta(P \times Q) \to MSG \wedge MSG$ is bordant to a globally transversal map $h: X \to MSG \wedge MSG$. Let

$$Y = h^{-1}(BSG \times BSG).$$

From Lemmas 3.11, 3.12, we know that

$$\text{index } (Y) = \text{index } (\delta L_i \times K \cup_{\delta P \times \delta Q} L_i \times \delta K) + \text{index } (L_0 \times \delta K)$$

$$= \text{index } (\delta L_i \times K) = \text{index } (\delta L_i \times K).$$

(We have used the Novikov additivity property to compute index $\delta L_i \times K \cup_{\delta P \times \delta Q} L_i \times \delta K$.) On the other hand,
index \((\delta L_4)\)
\[
= \phi_4 \rho_4 \delta [P^{4a+1}, f] - 4 \langle V S q^i V (\delta P) \cdot f^* \Phi (\widetilde{\Sigma}), [\delta P] \rangle
\]
\[
= 2^{a-1} \langle L(P) \cdot f^* \rho_2 (\beta l), [P] \rangle - 4 \langle V S q^i V (\delta P) \cdot f^* \Phi (\widetilde{\Sigma}), [\delta P] \rangle ,
\]
and, if \(s = 3\),
\[
\text{index } (K) = \phi_4 [Q^4, g] - 4 \langle V S q^i V (Q) \cdot g^* \Phi (\widetilde{\Sigma}), [Q] \rangle
\]
\[
= \langle L(Q) \cdot g^* \Phi (l), [Q] \rangle - 4 \langle V S q^i V (Q) \cdot g^* \Phi (\widetilde{\Sigma}), [Q] \rangle \in Z/8 .
\]

(If \(s < 3\), \(\rho_2 (\text{index } (K)) = \langle L(Q) \cdot g^* \Phi (\widetilde{\Sigma}), [Q] \rangle \in Z/2^a\)) Using 9.7, the reader can check that, for \(s \leq 3\), this gives
\[
\phi_4 \rho_4 \delta ([P^{4a+1}, f] [Q^4, g])
\]
\[
= 2^{a-1} \langle L(P) \cdot f^* \rho_2 (\beta l), [P] \rangle \langle L(Q) \cdot g^* \Phi (\widetilde{\Sigma}), [Q] \rangle \in Z/8 .
\]

By 9.9, this establishes 9.5 in Subcase 1.

**Subcase 2.** Let \(L^{4a+1} = f^{-1} (\text{BSG}) \subset P\), where \(f: P^{4a+1} \rightarrow \text{MSG}\) is transversal. Choose a \(Z/2\)-partition of the \(Z/2\)-manifold \(g: Q^{4b} \rightarrow \text{MSG}\), say \(Q = U_1 \cup U_2\). Thus \(U_1\) and \(U_2\) are \(Z/2\)-manifolds with boundary. The notation is \(\delta U_1 = U_1 \cap \partial Q\), \(\delta U_1 = U_1 \cap U_2 = \partial U_1\).

Note that \(\delta Q = \delta U_1 \cup \delta U_2\) will be a partition of \(g: \delta Q \rightarrow \text{MSG}\).

We have transversal inverse images, \(N_1 = g^{-1}(M') \cap U_1\) and \(N_2 = g^{-1}(M') \cap U_2\). \(N_1\) and \(N_2\) are also \(Z/2\)-manifold with boundary. The inclusion \(\partial N_2 \rightarrow \partial N_1\) is a normal map of \((4b - 2)\)-dimensional \(Z/2\)-manifolds and \(S \delta[Q^{4a}, g] \in Z/2\) is the surgery obstruction \(S \delta(\partial N_2 \rightarrow \partial N_1) \in Z/2\).

Since \(\delta(P \times Q) = \delta P \times Q \bigcup_{\partial P \times \delta Q} P \times \partial Q\), the partition \((Q, \delta Q) = (U_1 \cup U_2, \delta U_1 \cup \delta U_2)\) induces a partition of the closed manifold \(\delta(P \times Q)\). Namely,
\[
\delta(P \times Q) = (\delta P \times U_1) \bigcup_{\partial P \times \delta U_1} P \times \delta U_1\bigcup_{\partial P \times (U_1 \cap U_2) \cup P \times \delta(U_1 \cap \delta U_2)}
\]
\[
\times (\delta P \times U_2) \bigcup_{\partial P \times \delta U_2} P \times \delta U_2
\]
\[
= V_1 \cup V_2 .
\]
In the intersection, we get the "Massey product" normal map of closed $4a + 4b - 1$-dimensional PD spaces

$$\delta L \times \partial N_2 \cup L \times \partial N_2 \longrightarrow \delta L \times \partial N_1 \cup L \times \partial N_1.$$

By Lemma 3.12, the $\theta$-invariant of this normal map is given by

$$4d(L)\cdot S\delta(\partial N_2 \longrightarrow \partial N_1)
\begin{align*}
&= 4\langle V^*(P) \cdot f^* \Phi(VSq^1 V) + VSq^1 V(P) \cdot f^* \Phi(V^2), [P]\rangle \\
&\quad \times \langle V^2(\partial Q) \cdot g^* \Phi(\mathcal{K}), [\partial Q]\rangle.
\end{align*}$$

In $V_1$, we have

$$\delta L \times \partial N_i \cup L \times \partial N_i = \partial(\delta L \times N_i \cup L \times \partial N_i), \quad i = 1, 2.$$

**Lemma 9.10.**

$$\text{index}\left(\delta L \times N_1 \cup L \times \partial N_1\right)
+ \text{index}\left(\delta L \times N_2 \cup L \times \partial N_2\right) \equiv 0 \pmod{8}.$$

Assuming this lemma, we have shown that, if $f \times g: \delta(P \times Q) \longrightarrow \text{MSG} \wedge \text{MSG}$ is bordant to a transversal map $h: X \longrightarrow \text{MSG} \wedge \text{MSG}$, and $Y = h^{-1}(\text{BSG} \times \text{BSG}) \subset X$, then

$$\text{index}(Y)
= 4\langle V^*(P)f^* \Phi(VSq^1 V) + VSq^1 V(P) \cdot f^* \Phi(V^2), [P]\rangle \\
\quad \times \langle V^2(\partial Q) \cdot g^* \Phi(\mathcal{K}), [\partial Q]\rangle \in \mathbb{Z}/8.$$

From 9.7, we compute

$$\phi_\rho(\left[P^s\alpha, f\right][Q^b, g])
= 4\langle VSq^1(\partial P) \cdot f^* \Phi(\mathcal{K}), [\partial P]\rangle \langle V^2(Q) \cdot g^* \Phi(V^2), [Q]\rangle \\
+ 4\langle V^2(P) \cdot f^* \Phi(VSq^1 V), [P]\rangle \langle V^2(\partial Q) \cdot g^* \Phi(\mathcal{K}), [\partial Q]\rangle \in \mathbb{Z}/8.$$

The reader can check that this implies 9.5 in Subcase 2. (It is necessary to use index $(\delta L^s) = 0$, which implies $4\langle L(P) \cdot f^* \Phi_\rho(\mathcal{K}), [\rho L]\rangle = 4\langle VSq^1 V(\partial P) \cdot f^* \Phi(\mathcal{K}), [\partial P]\rangle$.)

**Proof of Lemma 9.10.** First, because of the computations above, this lemma is equivalent to 9.5 in our Subcase 2. If $g: Q^b \longrightarrow \text{MSG}$ is transversal, we know 9.5 holds because of Subcase 1. It thus suffices to consider a single non-transversal example $g: Q^b \longrightarrow \text{MSG}$.

We can thus assume that the manifolds $N_1$ and $N_2$, which arise
in the decomposition of $g: Q^4 \to MSG$, have a very simple form. Specifically, we assume $N_0 = D^4 \times S^3 \times I$, $\partial N_0 = S^3 \times S^3 \times I$, $\partial N_0 = D^4 \times S^3$, and $\partial \partial N_0 = S^3 \times S^3$ (the Kervaire 6-manifold), and we assume $N_1 = D^4 \times I$, $\partial N_1 = S^3 \times I$, $\partial N_1 = D^4$, and $\partial \partial N_1 = S^3$.

**Remark 9.11.** The $Z/2$-manifold $\partial N_i$ is obtained from $S^3 \times S^3 \times I$ via the diffeomorphism $T: S^3 \times S^3 \times \{0\} \to S^3 \times S^3 \times \{1\}$, $T(x, y, 0) = (y, x, 0)$. If we identify $S^3 \times S^3$ with $\partial(D^4 \times S^3)$ in such a way that the diagonal $\partial S^3 = \{(x, x)\} \sbs S^3 \times S^3$ bounds $D^4 \times 1 \sbs D^4 \times S^3$ (for example, via $S^3 \times S^3 \to S^3 \times S^3 \xrightarrow{id} D^4 \times S^3$ where $\mu(x, y) = (x, x^{-1}y))$, then the orientation-reversing diffeomorphism $T: S^3 \times S^3 \to S^3 \times S^3$ extends to $T: D^4 \times S^3 \to D^4 \times S^3$. This explains how we regard $N_2 = D^4 \times S^3 \times I$ as a $Z/2$-manifold with boundary.

Similarly, $N_i = D^4 \times I$ is a $Z/2$-manifold with boundary, via the diffeomorphism $T': D^4 \times \{0\} \to D^4 \times \{1\}$, $T'(x, 0) = (-x, 1)$.

With these assumptions, it is clear that index $(\partial L \times N_i) = 0$, $i = 1, 2$. We will prove now that

$$\text{index } (\partial L \times N_i \cup_{\partial \partial L \times \partial N_i} L \times \partial N_i) = \text{index } (\partial L \times N_i) + \text{index } (L \times \partial N_i), \quad i = 1, 2.$$  

This will prove Lemma 9.10.

We use the result of Wall on non-additivity of the signature [24]. Let $Y = Y_+ \cup Y_-$ be $4n$-manifolds with boundary. Let

$$X_0 = Y_+ \cap Y_-, \quad X_\pm = \partial Y_\pm - X_0, \quad Z = \partial X_0 = \partial X_\pm.$$  

Let $A, B, C \sbs H_{2n-1}(Z, Q)$ be the kernels of the maps from $H_{2n-1}(Z, Q)$ to $H_{2n-1}(X_+, Q)$, $H_{2n-1}(X_0, Q)$, $H_{2n-1}(X_-, Q)$, respectively. Then there is a non-singular symmetric quadratic form $\sigma: V \times V \to Q$, where $V = [A \cap (B + C)]/[A \cap B + A \cap C]$. Namely, if $a, a' \in A \cap (B + C)$, write $a + b + c = 0$ and $a' + b' + c' = 0$, where $b, b' \in B$ and $c, c' \in C$. Then define $\sigma(a, a') = \langle a \cup b', [Z] \rangle \in Q$. Moreover, index $(Y) = \text{index } (Y_+) + \text{index } (Y_-) \pm \text{index } (V, \sigma)$.

In the situation of Lemma 9.10, 

$$X_+ = \partial L \times \partial N_i, \quad X_0 = 2\partial L \times \partial N_i, \quad Z = 2\partial L \times \partial \partial N_i, \quad X_- = L \times \partial \partial N_i.$$
Thus, if \( i = 2 \),
\[
A = H_*(\delta L, Q) \otimes \text{kernel } (H_*(S^3 \times S^3 \times I, Q)) \rightarrow H_*(S^3 \times S^3 \times I, Q),
\]
\[
B = H_*(\delta L, Q) \otimes \text{kernel } (H_*(S^3 \times S^3 \times I, Q)) \rightarrow H_*(S^3 \times S^3 \times I, Q),
\]
\[
C = \text{kernel } (H_*(\delta L, Q) \rightarrow H_*(L, Q)) \otimes H_*(S^3 \times S^3, Q).
\]

Consider the automorphism of \( H_*(S^3 \times S^3, Q) \) defined by \( T(x \otimes y) = y \otimes x \). It is easy to see that \( T \) induces automorphisms of \( A, B, \) and \( C \), hence also an automorphism of \( V = [A \cap (B + C)]/[A \cap B + A \cap C] \). Moreover, the reader can check that \( \sigma(a, a') = -\sigma(Ta, Ta') \in Q \). It follows that index \( (V, \sigma) = 0 \) in this case.

If \( i = 1 \), it is easy to see directly that index \( (V, \sigma) = 0 \), since \( \partial N_i = S^7 \times I, \partial N_i = D^r \times \{0, 1\} \), and \( \partial \partial N_i = S^7 \) have such simple homology. This completes the proof of Lemma 9.10 and Subcase 2.

**Subcase 3.** We have \([P^{4a+1}, f][Q^{4b}, g] = [L^8][S^3, \alpha][Q^{4b}, g] \).

We first compute the global transversality obstruction
\[
s_2([L^8][S^3, \alpha][Q^{4b}, g])
\]
\[
= d(\delta L) \langle V^2([S^3, \alpha][Q^{4b}, g]) \rangle \text{ by Theorem 2.4(iv)}
\]
\[
= d(\delta L) \langle V^2([S^3, \alpha][Q^{4b}, g]) \rangle \text{ by 9.2}
\]
\[
= \langle V^2(Q) \cdot g^* \Phi(V^2), [Q]\rangle
\]
\[
= \langle V^2(Q) \cdot g^* \Phi(V^2), [Q]\rangle.
\]

Using 9.7 and 9.8, this implies \( \phi_\rho \delta([L^8][S^3, \alpha][Q^{4b}, g]) = 0 \). On the other hand, one can easily check that the RHS of 9.5 also vanishes in this special case. This proves Subcases 3, hence completes the discussion of Case 5.

**Proof of Case 3.** We wish to establish 9.5 for \([X, h] = [M^{4a+1}, f][N^{4b-1}, g], M, N \)

Z/8-manifolds. It suffices to consider the subcases: (1) \([N^{4b-1}, g] = [S^3, \alpha] \), and (2) \( g: N^{4b-1} \rightarrow MSG \) globally transversal. Let \([S^3, \alpha] = \partial [\bar{N}, \bar{\alpha}], \bar{N} \) a Z/8-manifold. Then \([M^{4a+1}, f][S^3, \alpha] = \rho_\delta([M^{4a+1}, f][\bar{\bar{N}}, \bar{\bar{\alpha}}]) + [\partial M, f|_M] [\bar{\bar{N}}, \bar{\bar{\alpha}}] \), and 9.5 holds in this case by our proofs of Cases 5 and 2 above. (Note that we did consider Bocksteins of Z/8-products in Case 5.)

Now assume that \( g: Q^{4b-1} \rightarrow MSG \) is globally transversal. This implies that \( f \times g: P^{4a+1} \times Q^{4b-1} \rightarrow MSG \land MSG \) is cobordant to a globally transversal map \( h: X \rightarrow MSG \land MSG \). Let \( k: R^5 \rightarrow MSG \) be a Z/8-manifold with \( \phi_\rho \delta[R^5, k] = 1 \in Z/8 \). (For example, the Pontrja-
gin-Thom construction applied to $CP(2)$ gives an element of $\pi_*(MSG)$ of order 8. This can be used to produce $[R^5, k]$. Consider the product $([P^{a+1}, f][Q^{b-1}, g])([R^5, k])$, which is cobordant to $[X^{a+4b}, h][R^5, k]$. In Subcase 1 of Case 5, we proved that

$$\phi\rho\delta([R^5, k][X^{a+4b}, h]) = \phi\rho\delta([R^5, k] \cdot [X^{a+4b}, h]) = \phi[X^{a+4b}, h] \in \mathbb{Z}/8.$$

On the other hand, let us compute $\phi\rho\delta$ by associating differently. We see

$$\phi\rho\delta(([Q^{b-1}, g])([P^{a+1}, f][R^5, k])) = 0,$$

from Subcase 1 of Case 4. Thus we have proved $\phi([P^{a+1}, f][Q^{b-1}, g]) = 0$ if $g: Q^{b-1} \to MSG$ is globally transversal. It is easy to check that the RHS of 9.5 also vanishes in this case.

This completes the proof of all five cases of 9.5, hence we have established 9.1.

**Chapter IV**

**10. Homotopy-theoretic obstructions to global transversality.**

Let $\xi \to B\xi$ be a spherical fibration, with Thom spectrum $T\xi$. In Chapter I, § 3, we defined certain homomorphisms (assuming $\pi_i(B\xi) = 0$ and $\xi$ oriented)

$$s_n: \tilde{\Omega}_{P,t+1}^n(T\xi, Z/n) \to P_n \otimes Z/n,$$

$$\bar{s}: \tilde{\eta}_{P,t+1}^n(T\xi) \to \mathbb{Z}/2,$$

using the obstruction theory to Poincaré transversality developed in I, §1 and §2. In this chapter, we will give purely homotopy-theoretic definitions of $s_n$ and $\bar{s}$. Since $\bar{s}$ determines $\tilde{s} \in H^{s-1}(BSG, \mathbb{Z}/2)$ and since $s_{2\infty} = \lim s_{2n}$, determines $\tilde{s} \in H^{s+1}(BSG, \mathbb{Z}/2)$, our homotopy-theoretic definitions of $\bar{s}$ and $s_{2\infty}$ give, in some sense, a homotopy-theoretic definition of the transversality obstructions $\tilde{s}$ and $\tilde{s}_{2\infty}$.

Among the consequences of the new definition are these. First, we can formulate homotopy-theoretic conditions which imply that $\tilde{s}$ and $\tilde{s}_{2\infty}$ vanish, and therefore, by Theorem 6.2, we can formulate conditions that imply a map $f: X \to BSG \langle g \rangle$ lifts to $f_{Top}: X \to BSTOP \langle g \rangle$. Secondly, we prove that, if $[M, f] \in \tilde{\eta}_{P,t+1}^n(T\xi)$ and if $f: M \to T\xi$ is globally transversal then $s([M, f]) = 0$. This proves the converse of Theorem 3.4 in the one case we did not deal with in §3 (see proof of Theorem 3.8). It also follows that $\bar{s}: \tilde{\eta}_{P,t+1}^n(T\xi) \to \mathbb{Z}/2$ is independent of the “good” cover $\langle V_\alpha \rangle$ of $T\xi$, which occurs implicitly in the original definition of $\bar{s}$ in §3. Thirdly, based on the new definition of $\bar{s}$, we
outline a purely homotopic-theoretic proof of the Whitney sum formula for the class $\xi$, namely, $\tilde{\xi}(\xi \times \eta) = \tilde{\xi}(\xi) \otimes V(\eta) + V(\xi) \otimes \tilde{\eta}(\eta)$. Finally, the new definition of $s$ applies to any spherical fiber space $\xi$, and the new definition of $s_n$ applies to any oriented $\xi$; that is, we drop the assumptions on $\pi(B\xi)$. (However, $\tilde{s}$ and $s_n$ are only partial obstructions to global transversality in the nonsimply connected case.)

We will first define $\tilde{s}: \eta \rightarrow L(T\xi) \rightarrow \mathbb{Z}/2$. The main idea is due to W. Browder ([3]). The homology theory $\eta \rightarrow L$ is represented by the spectrum $MPL$ (the Thom spectrum of the universal PL-bundle $\gamma \rightarrow BPL$). Thus, there is an isomorphism $p: \eta \rightarrow L(T\xi) \rightarrow \pi_*(T\xi \wedge MPL)$. $T\xi \wedge MPL$ is the Thom spectrum of the Whitney sum $\xi \times \gamma \rightarrow B\xi \times BPL$, and the isomorphism $p$ is easily defined directly as a Pontrjagin-Thom construction. Following Browder, we will define, for any spherical fiber space $\eta$, a homomorphism $\phi: \pi_2 \rightarrow \mathbb{Z}/2$. Then we define $s_{\xi}(\eta): \eta \rightarrow L(T\xi) \rightarrow \mathbb{Z}/2$ as the composition $s_{\xi}(\eta) = \phi \circ \eta \rightarrow L(T\xi) \rightarrow \pi_2 \rightarrow \mathbb{Z}/2$.

To define $\phi: \pi_2 \rightarrow \mathbb{Z}/2$, we recall some results of [3]. Let $K(\mathbb{Z}/2, n-1) \rightarrow B\eta(v_n\eta) \rightarrow B\eta$ be the fibration which kills the Wu class $v_n(\eta) \in H^n(B\eta, \mathbb{Z}/2)$. Let $T\eta(v_n\eta)$ be the Thom spectrum of the induced bundle over $B\eta(v_n\eta)$. Roughly, if $\alpha: S^{n-1} \rightarrow T\eta(v_n\eta)$ be the obstruction to lifting $\alpha$ to $\tilde{\alpha}: S^{n-1} \rightarrow T\eta(v_n\eta)$. We regard $B\eta(v_n\eta)$ as a subspace of $B\eta$. Let $v \in H^n(B\eta, B\eta(v_n\eta), \mathbb{Z}/2) = \mathbb{Z}/2$ be the generator. The composition

$$B\eta, B\eta(v_n\eta) \rightarrow B\eta \times (B\eta, B\eta(v_n\eta)) \rightarrow B\eta \times (K(\mathbb{Z}/2, n), e) ,$$

where $\Delta$ is the diagonal and $e \in K(\mathbb{Z}/2, n)$ is a basepoint, induces a map on the Thom space level

$$T\eta/T\eta(v_n\eta) \rightarrow T\eta \wedge K(\mathbb{Z}/2, n) / T\eta = T\eta \wedge K(\mathbb{Z}/2, n) .$$

**Theorem 10.1 (Browder).** (i) $f^*: H^*(T\eta \wedge K(\mathbb{Z}/2, n), \mathbb{Z}/2) \rightarrow H^*(T\eta/T\eta(v_n\eta), \mathbb{Z}/2)$ is an isomorphism if $i < 2n$, and a surjection with kernel $= \mathbb{Z}/2$ if $i = 2n$. The generator of kernel $(f^*_*)$ in dimension $2n$ is the element $v_n(\eta) \cdot U_\eta \otimes \iota_n + U_\eta \otimes \iota^2_n = \sum_{i=1} b_i v^i(\eta) \otimes \iota_n \in H^n(T\eta \wedge K(\mathbb{Z}/2, n), \mathbb{Z}/2)$, where $U_\eta \in H^*(T\eta, \mathbb{Z}/2)$ is the Thom class, and $\iota_n \in H^*(K(\mathbb{Z}/2, n), \mathbb{Z}/2)$ is the fundamental class.

(ii) Through dimension $2n$, $T\eta \wedge K(\mathbb{Z}/2, n)$ is a product of $K(\mathbb{Z}/2)$-spectra. Specifically, through dimension $2n$,

$$H^*(T\eta \wedge K(\mathbb{Z}/2, n), \mathbb{Z}/2)$$

is a free module over the Steenrod algebra $\mathcal{A}$, with basis $\{y U_\eta \otimes \iota_n\}$, where $\{y\} \in H^*(B\eta, \mathbb{Z}/2)$ is a $\mathbb{Z}/2$-basis.
(iii) Let \( y \in H(B\eta, \mathbb{Z}/2) \). Then \( \rho^* f_\eta^*(y U_\eta \otimes \tau_\eta) = y \cdot v_\eta \cdot U_\eta \in H^{n+i}(T\eta, \mathbb{Z}/2) \), where \( \rho: T\eta \rightarrow T\eta/T\eta \langle v_\eta \rangle \) is the obvious projection.

Proof. See [3] and [16].

It follows from 10.1(i) and (ii) that, through dimension \( 2n - 1 \), \( T\eta/T\eta \langle v_\eta \rangle \) is a 2-stage Postnikov system, with \( k \)-invariant

\[
X = \sum_{i=1}^n Sq^i(v_{n-i} \cdot U_\eta \otimes \tau_\eta) \in H^{2n}(T\eta \land K(\mathbb{Z}/2, n), \mathbb{Z}/2).
\]

In particular, there is an exact sequence

\[
0 \longrightarrow \mathbb{Z}/2 \longrightarrow \pi_{2n-1}(T\eta/T\eta \langle v_\eta \rangle) \xrightarrow{h} H_{2n-1}(T\eta/T\eta \langle v_\eta \rangle, \mathbb{Z}/2),
\]

where \( h \) is the Hurewicz homomorphism. Moreover, if \( \beta: \Sigma^{2n-1} \rightarrow T\eta/T\eta \langle v_\eta \rangle \) represents an element of kernel \( (h) = \mathbb{Z}/2 \), then \( \beta \) is evaluated as follows. Let \( x_{2n-i} = f_\eta^*(v_{n-i} \cdot U_\eta \otimes \tau_\eta) \in H^{2n-1}(T\eta/T\eta \langle v_\eta \rangle, \mathbb{Z}/2) \), so that \( \sum_{i=1}^n Sq^i(x_{2n-i}) = 0 \). Let \( \bar{x}_{2n-i} \in H^{2n-1}(T\eta/T\eta \langle v_\eta \rangle \cup \beta e^{2n}, \mathbb{Z}/2) \) be the unique element, \( 0 < i < n \), which restricts to

\[
x_{2n-i} \in H^{2n-1}(T\eta/T\eta \langle v_\eta \rangle, \mathbb{Z}/2).
\]

Then \( \beta \in \mathbb{Z}/2 \) is computed as the functional operation

\[
\sum_{i=1}^n Sq^i(\bar{x}_{2n-i}) \in \mathbb{Z}/2
\]

\[
= \text{image } (H^{2n-1}(\Sigma^{2n-1}, \mathbb{Z}/2) \xrightarrow{\delta} H^{2n}(T\eta/T\eta \langle v_\eta \rangle \cup \beta e^{2n}, \mathbb{Z}/2)).
\]

From 10.1, we also deduce the following.

Corollary 10.2. The composition \( \rho_* h: \pi_j(T\eta) \rightarrow \pi_j(T\eta/T\eta \langle v_\eta \rangle) \rightarrow H_j(T\eta/T\eta \langle v_\eta \rangle, \mathbb{Z}/2) \) is zero, \( j < 2n \). Hence

\[
\rho_* \pi_{2n-1}(T\eta) \subset \mathbb{Z}/2 \subset \pi_{2n-1}(T\eta/T\eta \langle v_\eta \rangle).
\]

Proof. By 10.1(i), (ii), it suffices to show that, for \( y \in H^i(B\eta, \mathbb{Z}/2) \), \( i < n \), the element \( \rho^* f_\eta^*(y U_\eta \otimes \tau_\eta) \in H^{n+i}(T\eta, \mathbb{Z}/2) \) is decomposable over the Steenrod algebra. But by 10.1(iii), and since \( Sq^n(y) = 0 \),

\[
\rho^* f_\eta^*(y U_\eta \otimes \tau_\eta) = y \cdot v_\eta \cdot U_\eta = y \cdot \chi(Sq^n) U_\eta
\]

\[
= \sum_{i=1}^n Sq^i(y \cdot \chi(Sq^{n-i}) U_\eta) + Sq^n(y) \cdot U_\eta
\]

\[
= \sum_{i=1}^n Sq^i(y \cdot v_{n-i} U_\eta).
\]

(We have used the identity \( Sq(a \cdot \chi(Sq)b) = Sq(a)(b) \).
We now define $\phi_n: \pi_{2n-1}(T\eta) \to Z/2$ to be 
$$\rho_n: \pi_{2n-1}(T\eta) \to \pi_{2n-1}(T\eta/T\eta\langle v_n \rangle)$$,
with image $(\rho_n) \subset Z/2 = \text{kernel}(h)$. Thus, given $\alpha: S^{2n-1} \to T\eta$, $\phi_n(\alpha) \in Z/2$ is computed as the functional operation 
$$\sum_{i=1}^{n} Sq^i(\bar{x}_{2n-i}) \in Z/2 \subset H^{2n}(T\eta/T\eta\langle v_n \rangle \cup e^{2n}, Z/2).$$

**Remark 10.3.** It is easy to see that $\phi_\eta$ commutes with bundle maps. That is, if $f: T\eta \to T\eta'$ is induced by a bundle map $f: \eta \to \eta'$, then $\phi_{\eta} = \phi_{\eta'} \circ f_\eta: \pi_{2n-1}(T\eta) \to Z/2$. It follows that, if $g: T\xi \to T\xi'$ is induced by a bundle map $g: \xi \to \xi'$, then $\delta_{\xi} = \delta_{\xi'} \circ g_\xi: \eta_{2n}^P(T\xi) \to Z/2$.

**Remark 10.4.** Suppose that $\eta$ is oriented, and that $n$ is odd. Then $\nu_\eta(\eta) = 0$, hence $\pi_{2n-1}(T\eta\langle v_n \rangle) \to \pi_{2n-1}(T\eta)$ is clearly surjective. Thus $\phi_\eta = 0: \pi_{4k+1}(T\eta) \to Z/2$. Since $\check{\Omega}_*^P(T\xi) = \pi_*(T\xi \land SPL)$, we see that, if $\xi$ is oriented, $\check{s} = 0: \check{\Omega}_{4k+1}^P \to Z/2$. With somewhat more work, one can prove that $\check{s} = 0: \check{\Omega}_{4k+1}^P(T\xi, Z/2) \to Z/2$. In fact, this will follow below when we prove that $\check{s} = \check{s}: \eta_{2n}^P(T\xi) \to Z/2$. The fact that $\check{s} = 0: \check{\Omega}_{4k+1}^P(T\xi, Z/2) \to Z/2$ follows from the result of Wall ([24]) that the Kervaire obstruction is zero for a normal map of $4k$-dimensional $Z/2$-manifolds.

We now begin the proof that $\check{s} = \check{s}: \eta_{2n}^P(MSP) \to Z/2$. It is easy to see that it suffices to prove kernel $(\check{s}) \subset \text{kernel}(\check{s})$ and $\check{s} = 0: \eta_{2n+1}^P(MSP) \to Z/2, n \geq 1$.

**Theorem 10.5 (Browder).** If $\alpha: S^{2n+1} \to T\eta$ is Poincaré-globally transversal, then $\phi_\eta(\alpha) = 0$.

**Proof.** We need to prove that $\alpha$ lifts to $\check{\alpha}: S^{2n+1} \to T\eta\langle v_n \rangle$. By assumption, $\alpha$ factors through the Thom space of the normal bundle of a PD space $L^{2n-1}, \alpha: S^{2n-1} \to T(v_{\eta}) \to T(\eta)$. Since $v_\eta(v_{\eta}) = v_\eta(L^{2n-1}) = 0$, we see that $\alpha$ lifts to $\check{\alpha}: S^{2n-1} \to T(v_{\eta}) \to T\eta\langle v_n \rangle$, as desired.

As a corollary, we see that, if $f: M^{2n-1} \to T\xi$ is Poincaré transversal, then $\delta[M, f] = \phi_{2n}(p[M, f]) = 0$, where $p: \eta_{2n+2n-1}(T\xi) \to \pi_{2n+2n-1}(T\xi \land MPL(2q))$ is the Pontrjagin-Thom map. For, if $f: M \to T\xi$ is transversal, then $p[M, f]: S \to T\xi \land MPL$ is transversal. In fact, the transversal inverse images $f^{-1}(B\xi) \subset M^{2n-1}$ and 
$$p[M, f]^{-1}(B\xi \land MPL(2q)) \subset S^{2n+2n-1},$$
can be identified as PD spaces, since $p[M, f]$ is defined in terms of
an embedding $M^{q+2n-1} \subset S^{q+2n-1}$. By Theorem 3.4, we conclude that, if $\tilde{s}[M, f] = 0$, then $s[M, f] = 0$; that is, kernel $(\tilde{s}) \subset$ kernel $(\tilde{s})$.

**Theorem 10.6.** If $n \geq 1$, $\tilde{s}: \eta_{2n+1}^{|\Omega|(MSG)} \to \mathbb{Z}/2$ is nonzero.

**Proof.** This is essentially due to Browder. Here is the idea. First, we will show that $\pi_3(\text{MSG}) = \mathbb{Z}/2$, and that $\phi: \pi_3(\text{MSG}) \to \mathbb{Z}/2$ and is nonzero. It is easy to see that the diagram

$$
\begin{array}{ccc}
\pi_{2n+1}(T^2) & \xrightarrow{\phi} & \mathbb{Z}/2 \\
\downarrow & & \downarrow \text{s} \\
\eta_{2n+1}(T^2) & \xrightarrow{\phi(s)} & \mathbb{Z}/2
\end{array}
$$

commutes, hence 10.6 is true if $n = 1$. Next, there is the natural action of $\eta_{*}^{PL}(pt)$ on $\eta_{*}^{PL}(T^2)$. We will show that, if $[M, f] \in \eta_{*}^{PL}(T^2)$ $[N] \in \eta_{*}^{PL}(pt)$, then

$$
(10.7) \quad \tilde{s}([M, f][N]) = \tilde{s}([M, f]) \cdot \langle V^i(N), [N] \rangle \in \mathbb{Z}/2.
$$

Thus we obtain 10.6 for $n > 1$ by taking $[M, f]$ to be the generator of $\pi_3(\text{MSG}) = \mathbb{Z}/2$ and $[N]$ to be $[\text{RP}(2n)]$.

To prove that $\pi_3(\text{MSG}) = \mathbb{Z}/2$, we recall ([14])

$$
H^i(\text{BSG}, \mathbb{Z}/2) = \begin{cases}
\mathbb{Z}/2 & \text{if } i = 0, \\
0 & \text{if } i = 1, \\
\mathbb{Z}/2 & \text{if } i = 2; \text{ generator } = w_2 = v_2, \\
\mathbb{Z}/2 \oplus \mathbb{Z}/2 & \text{if } i = 3; \text{ generator } = w_3 \text{ and } e_3.
\end{cases}
$$

Moreover, $Sq^0(e_3) \neq 0 \in H^i(\text{BSG}, \mathbb{Z}/2)$. (Here, $e_3 \in H^i(\text{BSG}, \mathbb{Z}/2)$ is the first exotic class ([17].) This computes $H^i(\text{MSG}, \mathbb{Z}/2)$, $i \leq 3$, and it is easy to deduce that

$$
\pi_i(\text{MSG}) = \begin{cases}
\mathbb{Z} & \text{if } i = 0, \\
0 & \text{if } i = 1, \\
0 & \text{if } i = 2, \\
\mathbb{Z}/2 & \text{if } i = 3.
\end{cases}
$$

(One knows from [17] that MSG is a product of $K(\pi)$-spectra, and it is easy to prove there is no odd torsion in this range.)

To see now that $\phi: \pi_3(\text{MSG}) \to \mathbb{Z}/2$ is nonzero, it is obviously sufficient to prove $\pi_3(\text{MSG} \langle v_3 \rangle) = 0$. From the Serre spectral sequence for $K(\mathbb{Z}/2, 1) \to BSG \langle v_3 \rangle \to BSG$, one computes
\[ H'(BSG\langle v_3 \rangle, \mathbb{Z}/2) = \begin{cases} \mathbb{Z}/2 & \text{if } i = 0 , \\ 0 & \text{if } i = 1 , \\ 0 & \text{if } i = 2 , \\ \mathbb{Z}/2 & \text{if } i = 3 ; \text{ generator } = \pi^n(e_3) . \end{cases} \]

Moreover, \( Sq^*(\pi^*e_3) \neq 0 \in H'(BSG\langle v_3 \rangle, \mathbb{Z}/2) \). Consider now the Postnikov system for \( MSG\langle v_3 \rangle \). It is clear that it must begin as

\[ K(\mathbb{Z}, 0) \cup_{Sq^*} K(\mathbb{Z}/2, 1) . \]

Now

\[ H'(K(\mathbb{Z}, 0) \cup_{Sq^*} K(\mathbb{Z}/2, 1), \mathbb{Z}/2) = \begin{cases} \mathbb{Z}/2 & \text{if } i = 0 , \\ 0 & \text{if } i = 1 , \\ 0 & \text{if } i = 2 , \\ \mathbb{Z}/2 & \text{if } i = 3 , \end{cases} \]

Moreover, the generator in dimension 3 restricts to

\( Sq^3 \kappa_1 \in H'(K(\mathbb{Z}/2, 1), \mathbb{Z}/2) . \)

From the well-known relation between \( \pi^*e_3 \cdot U \) and the secondary operation corresponding to the relation \( Sq^*Sq^* = 0 \in H'(K(\mathbb{Z}, 0), \mathbb{Z}/2) \) ([7]), we see that \( MSG\langle v \rangle \to K(\mathbb{Z}, 0) \cup_{Sq^*} K(\mathbb{Z}/2, 1) \) induces an isomorphism in cohomology through \( H^* \) and an injection in \( H^* \) Thus \( \pi_3(\text{MSG}\langle v \rangle) = 0 . \)

We will deduce 10.7 from the following product formula for \( \phi: \pi_*(T\eta) \to \mathbb{Z}/2 . \)

**Theorem 10.8.** Let \( \alpha: S^{2a-1} \to T_\xi \) and \( \beta: S^{2b-1} \to T_\eta \) be maps. Consider \( \alpha \land \beta: S^{2a+2b-1} = S^{2a-1} \land S^{2b-1} \to T_\xi \land T_\eta . \) Then

\[ \phi_{\times \times}(\alpha \land \beta) = \phi_\times(\alpha) \cdot \langle \beta^*\Phi(V^2), [S^{2a}] \rangle \in \mathbb{Z}/2 . \]

To derive 10.7 from 10.8, we have isomorphisms \( \eta_\times^*((T_\xi) \to \pi_*(T_\xi \land MPL) \) and \( p: \eta_\times^*(pt) \to \pi_!(MPL) . MPL \) is a ring spectrum with multiplication \( \mu: MPL \land MPL \to MPL \) induced by Whitney sum. The module structure of \( \eta_\times^*(T_\xi) \) over \( \eta_\times^*(pt) \) is then induced by

\( 1 \land \mu: T_\xi \land MPL \land MPL \to T_\xi \land MPL, \) and we have

\[ \tilde{s}(\varphi(M, f)[N] = \phi_{\times \times}(1 \land \mu)_*(p[M, f] \land p[N]) \]

\[ = \phi_{\times \times}(p[M, f]) \cdot \langle (p[N])^*\Phi(V^2)[S^{\dim N}] \rangle \text{ by Remark 10.3} \]

\[ = \phi_{\times \times}(p[M, f]) \cdot \langle (p[N])^*\Phi(V^2)[S^{\dim N}] \rangle \text{ by 10.8} \]

\[ = \tilde{s}((M, f)[N]) \cdot \langle V^2(N), [N] \rangle . \]

The product formula 10.7 implies that there is a graded class
\( \tilde{\mathcal{H}}(\xi) \in H^{r-1}(B\xi, \mathbb{Z}/2) \) such that, for any \( f: M \to T\xi \), \( \hat{s}(\langle M, f \rangle) = \langle V^\xi(M) \cdot \Phi(\tilde{\mathcal{H}}(\xi)), [M] \rangle \in \mathbb{Z}/2 \). The argument just above deriving \( 10.7 \) from \( 10.8 \) generalizes easily to give the following. Let \( f: M_{q+2a-1} \to T\xi, g: N^{q+2b} \to T\eta \) be maps. Then \( \hat{s}(\langle M \times N, f \land g \rangle) = \hat{s}(\langle M, f \rangle \land \langle g \circ \Phi(V^\xi), [N] \rangle \in \mathbb{Z}/2, \) where \( f \land g: M \times N \to T\xi \times T\eta \to T\xi \land T\eta \).

A simple argument then shows that the characteristic class \( \tilde{\mathcal{H}} \) satisfies the Whitney sum formula

\[
(10.9) \quad \tilde{\mathcal{H}}(\xi \times \eta) = \tilde{\mathcal{H}}(\xi) \otimes V^\xi(\eta) + V^\xi(\xi) \otimes \tilde{\mathcal{H}}(\eta) \in H^{r-\ast}(B\xi \times B\eta \mathbb{Z}/2, 2).
\]

If \( \pi(B\xi) = 0 \), then \( \hat{s} = \tilde{s}: \eta_*(T\xi) \to \mathbb{Z}/2 \). Thus \( \tilde{\mathcal{H}}(\xi) \) is the class \( \tilde{\mathcal{H}}_{r-1} \in H^{r-1}(B\xi, \mathbb{Z}/2) \) defined in II, \( \S 5 \). We have thus used 10.8 to prove a Whitney sum formula for \( \tilde{\mathcal{H}}_{r-1} \). In particular, consider \( \tilde{\mathcal{H}}_{r-1} \in H^{r-1}(BSG, \mathbb{Z}/2) \).

**Theorem 10.10.** \( \tilde{\mathcal{H}}_{r-1} = V^\xi(\sum_{i \geq 1} e_{2i-1}) \in H^{r-1}(BSG, \mathbb{Z}/2) \), where \( e_{2i-1} \in H^{2i-1}(BSG, \mathbb{Z}/2) \) is the unique primitive class with \( \sigma(e_{2i-1}) = i^*(\tilde{\mathcal{H}}_{2i-2}) \in H^{2i-2}(SG, \mathbb{Z}/2) \), \( \tilde{\mathcal{H}}_{2i-2} \in H^{2i-2}(G/TOP, \mathbb{Z}/2) \) the surgery obstruction class.

**Proof.** From 10.9, \( \tilde{\mathcal{H}}_{r-1} \cdot (V)^{-2} \in H^{r-1}(BSG, \mathbb{Z}/2) \) is primitive. On the other hand, \( \sigma(\tilde{\mathcal{H}}_{r-1} \cdot (V)^{-2}) = \sigma(\tilde{\mathcal{H}}_{r-1}) = i^*(\tilde{\mathcal{H}}_{r-2}) \) by 7.2. In [4], it is shown that \( i^*(\tilde{\mathcal{H}}_{4n-2}) = 0 \) if \( 4n \neq 2^l \). We also have \( j^*(\tilde{\mathcal{H}}_{r-1}) = 0 \in H^{r-1}(BSO, \mathbb{Z}/2) \), \( j: BSO \to BSG \). 10.10 now follows from the fact the primitives in \( H^*(BSG, \mathbb{Z}/2) \) which vanish in \( H^*(BSO, \mathbb{Z}/2) \) inject under \( \sigma \) into \( H^*(SG, \mathbb{Z}/2) \).

We now return to the proof of Theorem 10.8.

**Proof of 10.8.** **Step 1.** It suffices to assume \( v_1(\xi) = 0, i > a \), and \( v_1(\eta) = 0, j > b \), hence \( v_{a+b}(\xi \times \eta) = v_a(\xi) \otimes V_b(\eta) \). For let

\[
\bigvee_{i+j \geq 2\delta} K(\mathbb{Z}/2, a+i) \longrightarrow B\xi \longrightarrow B\xi
\]

be the fibration which kills \( v_{a+i+j}(\xi), i \geq 0 \). Similarly, define \( B\gamma \) by killing \( v_{b+j+1}(\eta), j \geq 0 \). Let \( T\xi \) and \( T\eta \) be the Thom spaces over \( B\xi \) and \( B\gamma \), respectively. It follows from 10.2 that \( \pi_{2a-1}(T\xi) \to \pi_{2a-1}(T\xi) \) and \( \pi_{2b}(T\eta) \to \pi_{2b}(T\eta) \) are surjective. If \( \tilde{\alpha}: S^{2a-1} \to T\xi \) and \( \tilde{\beta}: S^{2b} \to T\eta \) lift \( \alpha \) and \( \beta \), respectively, then, by Remark 10.3, \( \phi_{2a}(\alpha \land \beta) = \phi_{2a}(\tilde{\alpha} \land \tilde{\beta}) = \tilde{\phi}_{2a}(\tilde{\alpha} \land \tilde{\beta}) \in \mathbb{Z}/2 \), and also \( \phi_{a+b}(\alpha \land \beta \circ \Phi(V^\xi), [S^{2a}]) = \phi_{a+b}(\tilde{\alpha} \land \tilde{\beta} \circ \Phi(V^\xi), [S^{2a}]) \in \mathbb{Z}/2 \).

**Step 2.** There is a commutative diagram
\[
\begin{align*}
(T_\xi/T_\xi(v_a)) \land (T_\eta/T_\eta(v_b)) & \xrightarrow{f_\xi \times f_\eta} T_\xi \land K(Z/2, a) \land T_\eta \land K(Z/2, b) \\
\downarrow g & \quad \downarrow (1 \land 1 \land \tau_a \otimes \tau_b) \circ T \\
T_\xi \land T_\eta/T_\xi & \land T_\eta(v_a \otimes v_b) \xrightarrow{f_\xi \times f_\xi} T_\xi \land T_\eta \land K(Z/2, a + b)
\end{align*}
\]

where the map \( T \) switches the factors \( K(Z/2, a) \) and \( T_\eta \). Moreover, \( g \) is constructed so that

\[
\begin{align*}
(T_\xi/T_\xi(v_a)) & \land (T_\eta/T_\eta(v_b)) \\
\downarrow p \land p & \quad \downarrow g \\
T_\xi \land T_\eta & \quad \downarrow T_\xi \land T_\eta/T_\xi \land T_\eta(v_a \otimes v_b)
\end{align*}
\]

commutes.

To see this, one constructs on the base spaces a commutative diagram of maps of pairs

\[
\begin{align*}
(B_\xi, B_\xi(v_a)) \times (B_\eta, B_\eta(v_b)) & \xrightarrow{\partial(1 \times v_\xi) \times \partial(1 \times v_\eta)} B_\xi \times (K(Z/2, a), e) \\
\downarrow g & \quad \downarrow (1 \times 1 \times \tau_a \otimes \tau_b) \circ T \\
(B_\xi \times B_\eta, B_\xi \otimes B_\eta(v_a \otimes v_b)) & \xrightarrow{\partial(1 \times v_{\xi \times \eta})} (B_\xi \times B_\eta \times (K(Z/2, a + b), e), e)
\end{align*}
\]

where \( v_\xi \in H^a(B_\xi, B_\xi(v_a), Z/2) \), \( v_\eta \in H^b(B_\eta, B_\eta(v_b), Z/2) \), and \( v_{\xi \times \eta} \in H^{a+b}(B_\xi \times B_\eta, B_\xi \otimes B_\eta(v_a \otimes v_b), Z/2) \) are the unique nonzero elements.

**Step 3.** The functional operation

\[
\phi_{\xi \times \eta}(\alpha \land \beta)
= \sum_{i=1}^{a+b} S^q \left( \sum_{j \geq i} x_{2a-j} (\xi \times \eta) \otimes v_{b-k} U_\eta \right)
\in H^{a+b}(T_\xi/T_\xi(v_a)) \land T_\eta \land (\alpha \land \beta)
\]

can be computed as

\[
\begin{align*}
\sum_{i=1}^{a+b} S^q \left( \sum_{j \geq i} x_{2a-j} (\xi \times \eta) \otimes v_{b-k} U_\eta \right) \\
\in H^{a+b}(T_\xi/T_\xi(v_a)) \land T_\eta \land (\alpha \land \beta)
\end{align*}
\]

This follows easily from the existence of the commutative diagram

\[
\begin{align*}
\left( T_\xi/T_\xi(v_a) \right) & \land T_\eta \\
S^{a-1} \land S^{b} & \quad \downarrow g \\
T_\xi \land T_\eta/T_\xi & \land T_\eta(v_a, v_b)
\end{align*}
\]
Step 4. Finally, we employ the commutative diagram

\[
\begin{array}{ccc}
S^{2a-1} \wedge S^b & \longrightarrow & (T_\xi/T_\xi\langle v_a\rangle) \wedge T_\eta \\
1 \wedge \beta & \Longrightarrow & \downarrow h \\
S^{2a-1} \wedge T_\eta & \longrightarrow & (T_\xi/T_\xi\langle v_a\rangle) \wedge T_\eta
\end{array}
\]

\[
(T_\xi/T_\xi\langle v_a\rangle) \bigcup (\psi^2a+2b) \wedge T_\eta
\]

to show that

\[
\sum_{i=1}^{a+b} Sq^i \sum_{j+k=i} x_{2a-j}(\xi) \otimes v_{b-k}v_b U_0
\]

\[
= h^* \sum_{i=1}^{a+b} Sq^i \sum_{j+k=i} x_{2a-j}(\xi) \otimes v_{b-k}v_b U_0
\]

\[
= h^* \sum_{i=1}^a Sq^i (x_{2a-j}(\xi)) \otimes v_i U_0
\]

\[
= \phi_\xi(\alpha) \cdot \langle \beta^* \Phi(V^2), [S^{2a}] \rangle \in \mathbb{Z}/2.
\]

This completes our outline of the proof of 10.8. We leave the details of Steps 2, 3, and 4 to the reader.

We point out here that, if \( \xi \to B_\xi \) is a spherical fibration, \( \pi_i(B_\xi) = 0 \), then we have proved

**Theorem 10.12.** The following conditions are equivalent:

(a) Every map \( f: M^{q+2n-1} \to T_\xi^q \), \( q \gg 2n-1 \), \( M \) an unoriented manifold, is cobordant to a globally transversal map \( g: N^{q+2n-1} \to T_\xi^q \).

(b) \( J_\Gamma(f) = 0 \).

(c) \( \phi: \pi_{2n-1}(T_\xi^q \wedge MO) \to \mathbb{Z}/2 \) vanishes.

(Note that (c) is equivalent to the assertion that

\( \pi_{2n-1}((T_\xi^q \wedge MO)\langle v_a\rangle) \longrightarrow \pi_{2n-1}(T_\xi^q \wedge MO) \)

is surjective, \( n \geq 1 \). We can replace MPL by MO because the restricted homomorphism \( \tilde{s}: \tilde{\pi}_{2n-1}(T_\xi^q) \to \mathbb{Z}/2 \) is sufficient to define \( \tilde{\gamma}(\xi) \in H^{2n-2}(B_\xi, \mathbb{Z}/2) \).

Finally, we construct the map \( \alpha: K^{q+4} \to MSG_q \) used in 8.2. Recall \( K^{q+4} = S^{q+3} \times I/(x, 0) = (-x, 1) \) is a \( Z/2 \)-manifold with \( \overline{\partial}K^{q+4} = S^{q+3} \). Since \( \pi_0(MSG) = Z/2 \), there is a map \( \alpha: K^{q+4} \to MSG_q \) such that \( \alpha|_{S^{q+3}}: S^{q+3} \to MSG_q \) is the generator of \( \pi_0(MSG) \). Therefore, \( s\overline{\partial}(K^{q+4}, \alpha) = \tilde{s}(S^{q+3}, \alpha|_{S^{q+3}}) \neq 0 \). This establishes 8.2(i). Now there exist maps \( \beta: S^{q+4} \to MSG_q \) with \( \langle \beta^* \Phi(v), [S^{q+4}] \rangle \neq 0 \). (For example, \( \beta = \rho([CP(2)]) \), \( p: \Omega_\alpha(pt) \to \pi_0(MSG) \). Thus, if necessary, we can change \( \alpha: K^{q+4} \to MSG_q \) on a disc \( D^{q+4} \subset K^{q+4} \) such that \( \langle \alpha^* \Phi(V^2), [K^{q+4}] \rangle = 0 \). This establishes 8.2(ii).
11. Homotopy definition of $s_n: \Omega_{n+1}(T^n, Z/n) \to Z/n$. Our next goal is a homotopy-theoretic definition of $s_n: \Omega_{n+1}(T^n, Z/n) \to Z/n$, oriented. By Lemma 3.7, we need only consider $s_{2r}$, $r \geq 1$. Moreover, given $f: M^{2r+1} \to T^n$, we can assume $f|_{M^k}$ is globally transversal, and then $s_{2r}([M^{2r+1}, f])$ is computed as index $(L^k) \in Z/8$ (interpreted as an element of $Z/2^r$), where $L^k = f^{-1}(B^n \times Z/n)$. We will define, for any oriented spherical fibration $\eta$, a homomorphism $i: \pi_n(T\eta) \to Z/8$ with the following property: If $a: S^{4n+1} \to \pi_n(T\eta)$ is globally Poincaré-transversal, with $\alpha^{-1}(B\eta^n) = L^k \subset S^{(4n+1)}$, then $i(a) = \text{index}(L^k)$ (mod 8). As in the beginning of §10, there is a natural Pontrjagin-Thom isomorphism $p: \pi_n(T\eta) \to \pi_n(T\eta \times MSPL)$. Moreover, if $f: N \to T^n$ is globally transversal, then $p([N, f]): S^{4n+1} \to \pi_n(T\eta \times MSPL)$ is globally transversal, with $(p([N, f]))^{-1}(B^n \times BSPL) = f^{-1}(B^n)$ as P.D. spaces. It follows that $s_{2r}: \Omega_{n+1}(T^n, Z/2^r) \to Z/2^r$ is equal to the composition

$$
\Omega_{n+1}(T^n, Z/2^r) \xrightarrow{\delta} \Omega_{n+1}(T^n, Z/2^r) \xrightarrow{p} \pi_n(T^n \times MSPL) \xrightarrow{i} Z/8
$$

with image interpreted in $Z/2^r$.

Thus we need to define $i: \pi_n(\pi_n(T\eta)) \to Z/8$. The key idea is this: If $L^k$ is a closed, oriented PD space, then the Wu class $v_2(L) \in H^{2k}(L, Z/2)$ is the reduction of an integral class $v \in H^{2k}(L, Z)$, and, for any such choice of $v$, $\langle v, [L] \rangle \equiv \text{index}(L^k)$ (mod 8). Suppose the normal fibration of $L$ admits an $\eta$-orientation, $\nu: L \to B\eta$. Let $K(N, 2n) \to B\eta \langle \beta v \rangle \to B\eta$ be the fibration with $k$-invariant $\beta v \in H^{2k+1}(B\eta, Z)$. Then $\nu$ lifts to $\tilde{\nu}: L \to B\eta \langle \beta v \rangle$, and, on the Thom space level, $\alpha = p[L, \nu]: S^{4n} \to TV \to \pi_n(T^n \times MSPL)$ lifts to $\tilde{\alpha}: S^{4n} \to TV \to \pi_n(T^n \times MSPL)$. Moreover, if $\tilde{\nu} \in H^{2k}(B\eta \langle \beta v \rangle, Z)$ satisfies

$$
\rho(\tilde{\nu}) = \pi^*(v_2(L)) \equiv \text{index}(L^k) \equiv \langle \alpha^*\Phi(\tilde{\nu}), [S^{4n}] \rangle \text{ (mod 8)},
$$

then $\text{index}(L^k) \equiv \langle \alpha^*\Phi(\tilde{\nu}), [S^{4n}] \rangle \text{ (mod 8)}$.

**Theorem 11.1.** Given $\alpha: S^{4n} \to T\eta$, there exist liftings $\tilde{\alpha}: S^{4n} \to T\eta \langle \beta v \rangle$. Moreover, $\langle \alpha^*\Phi(\tilde{\nu}), [S^{4n}] \rangle \equiv \text{index}(L^k)$ (mod 8).

We therefore $i: \pi_n(T\eta) \to Z/8$ by $i(\alpha) = \langle \alpha^*\Phi(\tilde{\nu}), [S^{4n}] \rangle \equiv \text{index}(L^k)$ (mod 8). The point of Theorem 11.1 is that $i(\alpha)$ is defined for all $\alpha: S^{4n} \to T\eta$, regardless of whether $\alpha$ is transversal. If $\alpha: S^{4n} \to T\eta$ is transversal, $i(\alpha)$ gives the index (mod 8) of the inverse image of $B\eta$ because of the discussion above.

**Proof of 11.1.** Let $z \in H^{2k+1}(B\eta, B\eta \langle \beta v \rangle, Z) = Z$ be a generator.
The map on base spaces
\[ B\eta, B\eta \langle \beta v_{2n} \rangle \xrightarrow{\beta} B\eta \times (B\eta, B\eta \langle \beta v_{2n} \rangle) \xrightarrow{1 \times \beta} B\eta \times (K(Z, 2n + 1), e) \]
induces a map on Thom spaces
\[ T\eta \times T\eta \langle \beta v_{2n} \rangle \xrightarrow{g_*} T\eta \wedge K(Z, 2n + 1). \]

One can prove the following, just as Theorem 10.1 is proved in [1].

**LEMMA 11.2.**

(i) \( g_*^\beta : H^*(T\eta \wedge K(Z, 2n + 1), Z) \longrightarrow H^*(T\eta/T\eta \langle \beta v_{2n} \rangle, Z) \)

is an isomorphism if \( i < 4n + 2 \), and is a surjection with kernel = \( Z/2 \) if \( i = 4n + 2 \). The generator of kernel \((g_*^\beta)\) in dimension \( 4n + 2 \) is the element

\[
\begin{align*}
\beta v_{2n} U \otimes \tau_{2n+1} + U \otimes \tau_{2n+1} &= \beta(v_{2n} U \otimes \tau_{2n+1} + U \otimes Sq^{2n} \tau_{2n+1}) \\
&= \beta \left( \sum_{i=0}^{2n} Sq^{2i}(v_{2n-2i} U \otimes \tau_{2n+1}) \right) \in H^{4n+2}(T\eta \wedge K(Z, 2n + 1), Z).
\end{align*}
\]

(Recall that since \( \eta \) is oriented, \( v_j(\eta) = 0 \) if \( j \) is odd.)

(ii) If \( y \in H^*(B\eta, Z/p) \), \( p \) prime, then \( \rho^* g_*^\beta(y U \otimes \iota) = \beta v_{2n} \cdot y \cdot U \in H^*(T\eta, Z/p) \), where \( \rho : T\eta \rightarrow T\eta/T\eta \langle \beta v_{2n} \rangle \).

**COROLLARY 11.3.**

(i) \( (g_\#)_* : \pi_*(T\eta/T\eta \langle \beta v_{2n} \rangle) \rightarrow \pi_*(T\eta \wedge K(Z, 2n + 1)) \)

is an isomorphism if \( i \leq 4n \).

(ii) \( (g_\#)_* : \pi_*(T\eta) \rightarrow \pi_*(T\eta \wedge K(Z, 2n + 1)) \) is zero, \( i \leq 4n \).

**Proof.** (i) is immediate from Lemma 11.2(i). To prove (ii), first note that \( T\eta \wedge K(Z, 2n + 1) \) is the Eilenberg-MacLane spectrum \( K(H_{2n-1}(T\eta, Z)) \), through dimension \( 4n \). It thus suffices to prove that, for all \( y \in H^*(B\eta, Z/p) \), \( j < 2n \), \( \rho^* g_*^\beta(y U \otimes \iota) \in H^{2n+j}(T\eta, Z/p) \) is decomposable over the mod \( p \) Steenrod algebra. (We assume here that \( H_\ast(T\eta, Z) \) is of finite type.) If \( p \) is odd, this is obvious from Lemma 11.2(ii). If \( p = 2 \), we have

\[
\begin{align*}
\rho^* g_*^\beta(y U \otimes \iota) &= (Sq^i v_{2n}) \cdot y \cdot U = Sq^i (v_{2n} \cdot y \cdot U) + v_{2n} \cdot (Sq^i y) \cdot U \\
&= Sq^i (v_{2n} \cdot y \cdot U) + \sum_{i=1}^{n} Sq^{2i}(v_{2n-2i} \cdot (Sq^i v) \cdot U) + Sq^{2n}(Sq^i y) \cdot U \\
&= Sq^i (v_{2n} \cdot y \cdot U) + \sum_{i=1}^{n} Sq^{2i}(v_{2n-2i} (Sq^i y) \cdot U) + Sq^i (y \cdot (Sq^i y) \cdot U).
\end{align*}
\]

From Corollary 11.3(i) and (ii), we see that

\( \rho_* : \pi_{4n}(T\eta) \longrightarrow \pi_{4n}(T\eta/T\eta \langle \beta v_{2n} \rangle) \).
is zero, and the first statement of Theorem 11.1 follows.

We must now prove that, given
\[ \alpha \in \pi_{4n}(T\eta), \langle \bar{\alpha}^* \Phi(\partial^2), [S^{4n}] \rangle \in Z/8 \]
is independent of \( \bar{\alpha} \in H^{2n}(B\eta/\beta v_{2n}), \) lifting
\[ \pi^*(v_{2n}(\eta)) \in H^{2n}(B\eta/\beta v_{2n}, Z/2) \]
and independent of \( \bar{\alpha}_*: S^{4n} \to T\eta/\beta v_{2n} \) lifting \( \alpha: S^{4n} \to T\eta. \) First, \( \partial \) may be replaced by \( \partial + 2y, y \in H^{2n}(B\eta/\beta v_{2n}, Z). \) Then \( (\partial + 2y)^2 = \partial^2 + 4\beta y + 4y^2. \) It thus suffices to prove that \( \Phi(\rho_4(\partial y + y^2)) = v_{2n} \cdot y U + y^2 U \) is decomposable over the Steenrod algebra. But
\[ v_{2n} \cdot y U + y^2 U = y \cdot \chi(Sq^{2n}) U + Sq^{2n}(y) \cdot U = \sum_{i=1}^{n} Sq^{2i}(V_{2n-2i} \cdot y \cdot U). \]

Secondly, \( \bar{\alpha} \in \pi_{4n}(T\eta/\beta v_{2n}) \) may be replaced by \( \bar{\alpha} + \partial \beta, \beta \in \pi_{4n+1}(T\eta/\beta v_{2n}). \) The result that \( i(\alpha) = \langle \bar{\alpha}^* \Phi(\partial^2), [S^{4n}] \rangle \in Z/8 \) is independent of \( \bar{\alpha} \) follows immediately from

**Lemma 11.4.** Given any
\[ \beta: S^{4n+1} \to T\eta/T\eta/\beta v_{2n}, \langle \bar{\beta}^* \Phi(\partial^2), [S^{4n+1}] \rangle \equiv 0 \pmod{8}, \]
where \( \partial: H^{4n}(T\eta, Z) \to H^{4n+1}(T\eta/T\eta/\beta v_{2n}, Z). \)

**Proof.** We assert that \( \partial \Phi(\partial^2) = 4y, \) where \( \rho_4(y) \) is decomposable over the Steenrod algebra. Specifically,
\[ \rho_4(y) = g^*_5(v_{2n} U \otimes \iota + U \otimes Sq^{2n} \iota) = \sum_{i=1}^{n} Sq^{2i}(g^*_5(v_{2n-2i} U \otimes \iota)) \in H^{4n+1}(T\eta/T\eta/\beta v_{2n}, Z/2), \]
where \( g^*_5: T\eta/T\eta/\beta v_{2n} \to T\eta \wedge K(Z/2n + 1) \) was defined above. The lemma is immediate, given this assertion.

To see that \( \partial \Phi(\partial^2) \equiv 0 \pmod{4} \) is easy. If \( \pi: \beta \eta/\beta v_{2n} \to B\eta, \) we have \( \pi^*(v_{2n}) = \rho_4(\partial), \) hence \( \pi^*(\mathcal{P}(v_{2n})) = \rho_4(\partial^2), \) where
\[ \mathcal{P}(v_{2n}) \in H^{4n}(B\eta, Z/4) \]
is the Pontrjagin square of \( v_{2n}. \) Thus \( \rho_4(\partial^2) = 0 \in H^{4n+1}(B\eta, B\eta/\beta v_{2n}, Z/4). \) We need more delicate information about
\[ (\partial \partial^2) \in H^{4n+1}(B\eta, B\eta/\beta v_{2n}, Z), \]
so we work at the cochain level. Let \( c \in C^{4n}(B\eta, Z) \) be a cochain such that \( \pi^*(c) \in Z^{4n}(B\eta/\beta v_{2n}, Z) \) represents \( \bar{\alpha} \in H^{2n}(B\eta/\beta v_{2n}), Z \) and such that \( \rho_4(c) \in Z^{4n}(B\eta B\eta, Z/2) \) represents \( v_{2n} \in H^{2n}(B\eta, Z/2). \) Consider the cochain \( c \cup c + \delta c \cup \iota, c \in C^{4n}(B\eta, Z). \) (This is a \( Z/4 \)-cocycle which re-
presents $\mathcal{B}(v_{2n}) \in H^{*}(B\eta, Z/4)$.) Since

$$\pi^i(\delta c) = \delta(\pi^i c) = 0, \pi(c \cup c + \delta c \cup c) \in Z^{*n}(B\eta\langle\beta v_{2n}\rangle, Z)$$

represents $\delta^i$. Thus $\delta(\delta^i) \in H^{*n+1}(B\eta, B\eta\langle\beta v_{2n}\rangle, Z)$ is represented by the relative cocycle $\delta(c \cup c + \delta c \cup c) = 2(\delta c) \cup c + \delta c \cup \delta c$ (see [23], Theorem 5.1 for the coboundary of $\cup$-products). On the other hand, $\delta c = 2d$, where $d \in Z^{2n+1}(B\eta, B\eta\langle\beta v_{2n}\rangle, Z)$ represents the generator $z \in H^{2n+1}(B\eta, B\eta\langle\beta v_{2n}\rangle, Z)$. Thus $\delta^i(\delta^i)$ is represented by the relative cocycle $4(d \cup c + d \cup d)$. Clearly, $\rho_{i}(d \cup c + d \cup d)$ represents the cohomology class $v_{2n} \cdot z + Sq^{2n}(z) \in H^{*n+1}(B\eta, B\eta\langle\beta v_{2n}\rangle, Z/2)$.

Now consider the maps

$$B\eta, B\eta\langle\beta v_{2n}\rangle \xrightarrow{\delta^i} B\eta \times (B\eta, B\eta\langle\beta v_{2n}\rangle) \xrightarrow{1 \times z} B\eta \times (K(Z, 2n + 1), e),$$

which induce on the level of Thom spaces the map

$$g_{\eta}: T\eta/T\eta\langle\beta v_{2n}\rangle \longrightarrow T\eta \wedge K(Z, 2n + 1).$$

Under the "Thom isomorphism"

$$H^*(B\eta, B\eta\langle\beta v_{2n}\rangle, Z/2) \xrightarrow{\sim} H^*(T\eta/T\eta\langle\beta v_{2n}\rangle, Z/2),$$

$v_{2n} \cdot z$ corresponds to $g_{\eta}^*(v_{2n} U \otimes \tau_{2n+1})$, and $Sq^{2n}(z)$ corresponds to $g_{\eta}^*(U \otimes Sq^{2n} \tau_{2n+1})$. Thus $\delta^i(\delta^i) = 4y$, where

$$\rho_{i}(y) = g_{\eta}^*(v_{2n} U \otimes \tau + U \otimes Sq^{2n} \tau),$$

as asserted.

Finally, we point out that, if $\xi \to B\xi$ is an oriented spherical fibration, $\pi_{i}(B\xi) = 0$ and if $\mathcal{X}(\xi) \in H^{*+1}(B\xi, Z/2)$ is the class defined in §5 (and in this section), then we have proved

**Theorem 11.5.** The following conditions are equivalent:

(a) Every map $f: M^{q+4n+1} \to T\xi^q$, $q \geq 4n + 1$, $M$ a $Z/2$-manifold, is cobordant to a globally transversal map $g: N^{q+4n+1} \to T\xi^q$.

(b) $\mathcal{X}(\xi) = 0$.

(c) $i^* \pi_{i}(T\xi^q \wedge MSO) \to Z/8$ vanishes on the torsion subgroup of $\pi_{i}(T\xi^q \wedge MSO)$.

(Note that (c) is equivalent to the assertion that

$$i\delta: \pi_{i+1}(T\xi^q \wedge MSO, Z/2^r) \to \pi_{i}(T\xi^q \wedge MSO) \to Z/8$$

vanishes. We can replace $MSPL$ by $MSO$ since the restricted homomorphisms $s_{2r}: \tilde{D}_{i+1}(T\eta^r, Z/2^r) \to Z/2^r$, $r \geq 1$, are sufficient to define the class $\mathcal{X}(\xi) \in H^{i+1}(B\xi, Z/2)$.)
APPENDIX. Constructing cohomology classes from homomorphisms on bordism. In this Appendix, we review the technique used by Sullivan (and earlier by Thom in his definition of rational PL-Pontrjagin classes) of defining cohomology classes of a space \( Y \) in terms of homomorphisms on the smooth bordism of \( X \). We deal separately with cohomology classes with \( \mathbb{Z}/2 \), \( \mathbb{Q} \), \( \mathbb{Z} \), and \( \mathbb{Z}/2 \) coefficients.

Case \( \mathbb{Z}/2 \). The key fact for the construction is the result of Thom, that the Hurewicz homomorphism \( h_n : \pi_n(X) \to H_n(X, \mathbb{Z}/2) \) is surjective, and that kernel \( (h_n) \) is generated over \( \mathbb{Z}/2 \) by the decomposable elements in the image of the natural pairing \( \mathcal{R}_n(X) \otimes \mathcal{R}_n(pt) \to \mathcal{R}_n(X) \), that is, by elements \([M, f] \cdot [N] = [M \times N, f \pi_i] \), where \( f : M^{s-1} \to X \) and \( i > 0 \).

As an immediate consequence, we have that a cohomology class \( z \in H^n(X, \mathbb{Z}/2) \), which is the same as a homomorphism \( H_n(X, \mathbb{Z}/2) \to \mathbb{Z}/2 \), is equivalent to a homomorphism \( \phi_n : \mathcal{R}_n(X) \to \mathbb{Z}/2 \) such that \( \phi([M, f] \cdot [N]) = 0 \) whenever \( \dim(N) > 0 \).

In practice, the homomorphisms \( \phi_n : \mathcal{R}_n(X) \to \mathbb{Z}/2 \) which arise do not vanish on decomposables, but satisfy a product formula like

\[
\phi_n([M, f] \cdot [N]) = \phi_n([M, f]) \cdot \chi(N),
\]

where \( \chi(N) \) is the Euler characteristic of \( N \), modulo 2. In such a situation, we obtain a (graded) cohomology class \( z = z_0 + z_1 + z_2 + \cdots \), \( z_n \in H^n(X, \mathbb{Z}/2) \), as follows. Perturb the Hurewicz homomorphism \( h \) to \( \tilde{h} : \mathcal{R}_n(X) \to H_n(X, \mathbb{Z}/2) \) by setting

\[
\tilde{h}(M, f) = f_*(V^*(M) \cap [M]) \in H_n(X, \mathbb{Z}/2),
\]

where \( V^*(M) = 1 + v^s(M) + v^s(M) + \cdots \) is the square of the total Wu class of \( M \). The homomorphism \( \tilde{h} \) is not homogeneous; that is, \( \tilde{h} \) is not degree-preserving. However, \( \tilde{h} \) is still surjective, and kernel \( (\tilde{h}) \) is generated over \( \mathbb{Z}/2 \) by elements \([M, f] \cdot [N] - [M, f] \cdot V^*(N) \cdot [N] \), where \( \langle V^*(N), [N] \rangle = \chi(N) \in \mathbb{Z}/2 \). Thus we have

**Proposition A.1.** Graded classes \( z_n \in H^n(X, \mathbb{Z}/2) \) correspond bijectively to homomorphisms \( \phi_n : \mathcal{R}_n(X) \to \mathbb{Z}/2 \) which satisfy \( \phi_n([M, f] \cdot [N]) = \phi_n([M, f]) \cdot \chi(N) \in \mathbb{Z}/2 \). The correspondence is defined by the equation

\[
\phi_n(M, f) = \langle V^*(M) \cdot f^*(z_n), [M] \rangle \in \mathbb{Z}/2.
\]

**Proof.** This follows easily from the above properties of \( \tilde{h} : \mathcal{R}_n(X) \to H_n(X, \mathbb{Z}/2) \), the relation \( V^*(M \times N) = V^*(M) \otimes V^*(N) \in H^*(M, \mathbb{Z}/2) \otimes H^*(N, \mathbb{Z}/2) = H^*(M \times N, \mathbb{Z}/2) \), and the computation
\[ \langle V^*(M) \cdot f^*(z_*), [M] \rangle = \langle f^*(z_*), V^*(M) \cap [M] \rangle = \langle z_*, \tilde{h}[M, f] \rangle. \]

**Remark A.2.** Since \( V^2 = 1 + v_1 + v_2 + \cdots \) is nonzero only in even dimensions, we have that, if \( f: M^* \to X \) is a map, then

\[ \phi_n(M^*, f) = \langle V^*(M) \cdot f^* \left( \sum_{n \geq 2} z_{n-2i} \right), [M] \rangle. \]

That is, the homomorphism \( \phi_n, n \text{ even} \), is determined by the classes \( z_3, z_5, \ldots \), and the homomorphism \( \phi_n, n \text{ odd} \), is determined by the classes \( z_1, z_3, z_5, \ldots \).

\( Z/2 \)-cohomology classes can also be defined by using the homology theory "bordism with \( Z/2 \)-coefficients," \( \Omega_*(pt, Z/2) \). Namely, \( \Omega_*(X, Z/2) \) is a module over \( \Omega_*(pt, Z/2) \), the Hurewicz homomorphism

\[ h: \Omega_*(X, Z/2) \to H_*(X, Z/2) \]

is surjective, and kernel \( (h) \) is generated by decomposable elements \( [M, f] \cdot [N] \). As in Proposition A.1, we deduce

**Proposition A.3.** A graded class \( z_* H^*(X, Z/2) \) is equivalent to a homomorphism \( \phi_*: \Omega_*(X, Z/2) \to Z/2 \) which satisfies \( \phi_*([M, f] \cdot [N]) = \phi_*([M, f]) \chi(N) \). The correspondence is defined by

\[ \phi_*([M, f]) = \langle Y^*(M) \cdot f^* (z_*), [M] \rangle \in Z/2. \]

**Remark A.4.** Since for \( Z/2 \)-manifolds \( M, w^i(M) = 0 \), and since \( v_{2i+1} \) is always divisible by \( w_i \), we have that \( V^0(M) = 1 + v_2(M) + v_2(M) + \cdots \) is nonzero only in dimensions divisible by 4. Thus

\[ \phi_n(M^*, f) = \langle V^*(M) \cdot f^* \left( \sum_{n \geq 2} z_{n-4i} \right), [M^*] \rangle \in Z/2. \]

**Case Q.** Another simple case when cohomology classes are directly constructed from homomorphisms on bordism is the case of rational coefficients. Specifically, the Hurewicz homomorphism \( h: \Omega_*(X) \otimes Q \to H_*(X, Q) \) is again surjective and kernel \( (h) \) is generated, over \( Q \), by decomposable elements \( [M, f] \cdot [N], [M, f] \in \Omega_*(X), [N] \in \Omega_*(pt) \), and \( \dim (N) > 0 \). Thus homomorphisms \( \phi_*: \Omega_*(X) \otimes Q \to Q \) which vanish on decomposables yield rational cohomology classes.

In practice, the homomorphisms \( \phi_*: \Omega_*(X) \otimes Q \to Q \) which arise satisfy a product formula like \( \phi_*([M, f] \cdot [N]) = \phi_*([M, f]) \cdot \text{index} (N) \).

Let \( L_q(M) = 1 + L_q(M) + L_q(M) + \cdots \in H^*(M, Q) \) be the (inverse) Hirzebruch polynomial of the normal bundle of \( M \) (so that \( \langle L_q(M), [M] \rangle = \text{index} (M) \in Z \)). Then we have

**Proposition A.5.** Graded classes \( z_* \in H^*(X, Q) \) correspond bijec-
tively with homomorphisms \( \phi_\ast : \Omega_\ast(X) \otimes \mathbb{Q} \to \mathbb{Q} \) which satisfy
\( \phi_\ast([M, f] \cdot [N]) = \phi_\ast([M, f]) \cdot \text{index}(N) \). The correspondence is defined
by the equation
\[
\phi_\ast(M^n, f) = \left\langle L_0(M^n) \cdot f^\ast\left(\sum_{a=0}^{n-1} z_{a-n}\right), [M^n]\right\rangle \in \mathbb{Q}.
\]

Case \( Z_{(2)} \). A somewhat more complicated situation arises if we attempt to define a cohomology class with \( Z_{(2)} \)-coefficients. A complete
discussion is given in [15]. We state here only the final results of
that discussion. Roughly, the idea is that a \( Z_{(2)} \)-class determines by
obvious coefficient maps (and is determined by \( \lambda \)) a \( \mathbb{Q} \)-class and a
compatible set of \( Z/2^r \)-classes, \( r \geq 1 \).

Here are the relevant facts.

1. The evaluation map \( H^n(X, \mathbb{Z}/2^r) \sim \text{Hom}(H^n(X, \mathbb{Z}/2^r), \mathbb{Z}/2^r) \)
is an isomorphism.

2. The Hurewicz map \( h_\ast(\mathbb{Z}/2^2) : \Omega_\ast(X, \mathbb{Z}/2^2) \to H_\ast(X, \mathbb{Z}/2^2) \)
is surjective.

3. There is a natural module structure
\[
\Omega_\ast(X, \mathbb{Z}/2^2) \otimes \Omega_\ast(pt, \mathbb{Z}/2^2) \longrightarrow \Omega_\ast(X, \mathbb{Z}/2^2)
\]
and, in the limit, kernel \( (h_\ast(2^2) : \Omega_\ast(X, \mathbb{Z}/2^2) \to H_\ast(X, \mathbb{Z}/2^2)) \)
is generated by “products” \( i([M, f] \cdot [N]), \) where \( \mathbb{Z}/2^2 = \lim \mathbb{Z}/2^r, \ i : \mathbb{Z}/2^r \to \mathbb{Z}/2^r \).

4. The rational \( L \)-class \( L_\mathbb{Q} = 1 + L_4 + L_8 + \cdots \in H^n(BSO, \mathbb{Q}) \), used in
Case \( Q \) above, can be refined to a unique class \( L \in H^n(BSO, Z_{(2)}) \) which
satisfies \( \rho_\mathbb{Q}(L) = L_\mathbb{Q} \in H^n(BSO, \mathbb{Q}) \) and \( \rho_\lambda(L) = V^2 \in H^n(BSO, \mathbb{Z}/2) \). Moreover,
\( L \) is multiplicative; that is, on Whitney sums of bundles,
\( L(\xi + \eta) = L(\xi) \cdot L(\eta) \).

Using these facts, the following is proved in [15].

**Proposition A.6.** Graded classes \( z_\ast \in H^n(X, Z_{(2)}) \) correspond bijective
ly with commutative diagrams

\[
\begin{array}{ccc}
\Omega_\ast(X) \otimes \mathbb{Q} & \xrightarrow{\phi_\mathbb{Q}} & \mathbb{Q} \\
\downarrow \rho && \downarrow \rho \\
\Omega_\ast(X, \mathbb{Z}/2^2) & \xrightarrow{\phi_\lambda} & \mathbb{Z}/2^\infty,
\end{array}
\]

where \( \rho : \mathbb{Q} \to \mathbb{Q}/Z_{(2)} = \mathbb{Z}/2^\infty \) is the projection, which satisfy

1. \( \phi_\mathbb{Q}([M, f] \cdot [N]) = \phi_\mathbb{Q}([M, f]) \cdot \text{index}(N) \in \mathbb{Q}, \)
2. \( \phi_\lambda(i([P, g] \cdot [Q])) = \phi_\lambda(i([P, g])) \cdot \text{index}(Q) \in \mathbb{Z}/2^r \subset \mathbb{Z}/2^\infty, \)
where $P$ and $Q$ are $\mathbb{Z}/2^r$-manifolds, $i: \mathbb{Z}/2^* \rightarrow \mathbb{Z}/2^r$. The correspondence is defined by the equations

$$\phi_q([M^*], f) = \langle L(M^*) \cdot f^* \left( \sum_{i \geq 0} z_{-a_i} \right), [M] \rangle \in \mathbb{Z}_{(2)} \subset Q,$$

where $[M, f] \in \Omega_n(X)$, and

$$\phi_q(i[P^*, g]) = \langle L(P^*) \cdot g^* \left( \sum_{i \geq 0} z_{-a_i} \right), [P] \rangle \in \mathbb{Z}/2^r \subset \mathbb{Z}/2^r,$$

where $[P^*, g] \in \Omega_n(X, \mathbb{Z}/2^r)$.

**Remark A.7.** It is clear that the torsion classes in $H^*(X, \mathbb{Z}_{(2)})$ correspond to the diagrams in A.6 with $\phi_Q \equiv 0$.

**Case $\mathbb{Z}/2^r$.** The final result that we need for this paper is a construction of cohomology classes with $\mathbb{Z}/2^r$-coefficients, $r > 1$ (see §8). Now, we have the isomorphism

$$H^*(X, \mathbb{Z}/2^r) \xrightarrow{\sim} \text{Hom}(H_*(X, \mathbb{Z}/2^r), \mathbb{Z}/2^r)$$

and the surjection $h_*(2^r): \Omega_*(X, \mathbb{Z}/2^r) \rightarrow H_*(X, \mathbb{Z}/2^r)$, as mentioned in Case $\mathbb{Z}_{(2)}$ above. However, kernel $(h_*(2^r))$ is somewhat complicated, and before we can define $\mathbb{Z}/2^r$-cohomology classes, we must study this kernel.

First, consider $h_*: \Omega_*(X) \rightarrow H_*(X, \mathbb{Z})$, which is surjective modulo the class of finite groups of odd order. We know that, since MSO localized at 2 is an Eilenberg-MacLane spectrum, there is an isomorphism $\Omega_*(X) = H_*(X, \Omega_*(pt))$ (mod groups of odd order). Thus there is an exact sequence

$$0 \rightarrow H_*(X, Z) \otimes \Omega_*(pt) \rightarrow \Omega_*(X) \rightarrow \text{Tor}_{\mathbb{Z}/2}(H_*(X, Z), \Omega_*(pt)) \rightarrow 0$$

(mod groups of odd order). We choose a subgroup of $\Omega_*(X)$ isomorphic to $H_*(X, Z)$ under $h$, $H_*(X, Z) \subset \Omega_*(X)$. Then elements in image ($H_*(X, Z) \otimes \Omega_*(pt) \rightarrow \Omega_*(X)$) are clearly constructed as products $[M, f] \cdot [N], [M, f] \in H_*(X, Z), [N] \in \Omega_*(pt)$. Now the torsion in $\Omega_*(pt)$ consists of elements of order 2 ([24]). Let $f: P^m \rightarrow X$ represent an element of order 2 in $H_*(X, Z)$, and let $Q^* \in \Omega_*(pt)$ have order 2. We construct an element $[P, f] \cdot [Q] \in \Omega_{m+n+1}(X)$, which hits the torsion product $[P, f] \cdot [Q] \in \text{Tor}(H_*(X, Z), \Omega_*(pt))$, as follows. Let $F: \tilde{P} \rightarrow X$ satisfy $\partial F = 2P, F|_{\partial P} = 2f$, and let $\partial Q = 2Q$. Form the map

$$\tilde{F} \circ \pi_1 \cup f \circ \pi_1: \tilde{P} \times Q \cup P \times \tilde{Q} \rightarrow X.$$
This is our desired element of $\Omega_{m+n+1}(X)$. Note that this element belongs to the Massey product $\langle [P, f], 2, [Q] \rangle$. Of course, it is not well-defined, but depends on the choices $\tilde{P}, \tilde{F}$, and $\tilde{Q}$. The indeterminacy is clearly the same as that of the Massey product $\langle [P, f], 2, [Q] \rangle$, namely, the products with $[P, f]$ or $[Q]$ as one factor:

$$[P, f] \otimes \Omega_{n+1}(pt) + \Omega_{m+1}(X) \otimes [Q] \subset \Omega_{m+n+1}(X).$$

We point out that $\tilde{P}$ and $\tilde{Q}$ give $\mathbb{Z}/2$-manifolds in the obvious way, and the Massey product constructed above is the Bockstein of the product of the $\mathbb{Z}/2$-manifolds $\tilde{P}$ and $\tilde{Q}$. That is ([15]),

$$\langle [P, f], 2, [Q] \rangle = \delta([\tilde{P}, \tilde{F}] \otimes [\tilde{Q}]),$$

where $\delta: \Omega_{*+(X, \mathbb{Z}/2)} \rightarrow \Omega_{*}(X)$ is the Bockstein.

The description of generators of $\Omega_{*}(X)$ given above easily implies

**Lemma A.8.** kernel $(h_\ast: \Omega_{*}(X) \rightarrow H_{*}(X, \mathbb{Z}))$ is generated (mod groups of odd order) by

1. Products $[M, f] \cdot [N], \dim(N) > 0$ and
2. Bocksteins of products $\delta([\tilde{P}, \tilde{F}] \cdot [\tilde{Q}]),$ where $\tilde{P}$ and $\tilde{Q}$ are $\mathbb{Z}/2$-manifolds and $\dim(\tilde{Q}) > 0$.

Next, we consider the relation between $\Omega_{*}(X)$ and $\Omega_{*}(X, \mathbb{Z}/2^r)$. There is a commutative diagram

$$
\begin{array}{ccccccccc}
0 & \longrightarrow & \text{kernel}(h_\ast) & \longrightarrow & \Omega_{*}(X) & \longrightarrow & H_{*}(X, \mathbb{Z}) & \longrightarrow & 0 \\
& & \downarrow \rho_{2^r} & & \downarrow \rho_{2^r} & & \downarrow \rho_{2^r} & & \\
0 & \longrightarrow & \text{kernel}(h_{\ast}(2^r)) & \longrightarrow & \Omega_{*}(X, \mathbb{Z}/2^r) & \longrightarrow & H_{*}(X, \mathbb{Z}/2^r) & \longrightarrow & 0 \\
(A.9) & & \downarrow \delta & & \downarrow \delta & & \downarrow \delta & & \\
0 & \longrightarrow & \text{kernel}(h_{\ast-1}) & \longrightarrow & \Omega_{*}(X) & \longrightarrow & H_{*}(X, \mathbb{Z}) & \longrightarrow & 0 \\
& & \downarrow 2^r & & \downarrow 2^r & & \downarrow 2^r & & \\
0 & \longrightarrow & \text{kernel}(h_{\ast-1}) & \longrightarrow & \Omega_{*}(X) & \longrightarrow & H_{*}(X, \mathbb{Z}) & \longrightarrow & 0 
\end{array}
$$

The columns are exact and the rows are exact modulo groups of odd order.

**Lemma A.10.** kernel $(h_{\ast}(2^r): \Omega_{*}(X, \mathbb{Z}/2^r) \rightarrow H_{*}(X, \mathbb{Z}/2^r))$ is generated by

1. products $[M, f] \cdot [N], [M, f] \in \Omega_{*}(X, \mathbb{Z}/2^r), [N] \in \Omega_{*}(pt), \text{ and dim}(N) > 0.$
(ii) \( \mathbb{Z}/2 \)-products \( i([\tilde{M}, \tilde{f}] \cdot [\tilde{N}]), [\tilde{M}, \tilde{f}] \in \Omega_*(X, \mathbb{Z}/2), [\tilde{N}] \in \Omega_*(pt, \mathbb{Z}/2), \dim (\tilde{N}) > 0, \) and \( i = 2^{-1}: \Omega_*(X, \mathbb{Z}/2) \to \Omega_*(X, \mathbb{Z}/2') \).

(iii) \( \mathbb{Z}/2 \)-reductions of Bocksteins of products, \( \rho_* \delta([\tilde{P}, \tilde{F}] \cdot [\tilde{Q}]), [\tilde{P}, \tilde{F}] \in \Omega_*(X, \mathbb{Z}/2), [\tilde{Q}] \in \Omega_*(pt, \mathbb{Z}/2), \) and \( \dim (\tilde{Q}) > 0. \)

**Proof.** From Diagram A.9, we see that kernel \( (h_*(2')) \) is generated by \( \rho_* \text{(kernel \( (h_*) \))}, \) together with a set of elements \( \{x_i\} \) such that \( \delta[x_i] = \text{kernel \( (h_*) \) \cap kernel \( (2') \)). \) By Lemma A.8, \( \rho_* \text{(kernel \( (h_*) \)) is generated by \( \rho_*([M, f] \cdot [N]) = \rho_*([M, f]) \cdot [N], \dim (M) + \dim (N) = n, \) and \( \dim (N) > 0, \) together with \( \rho_* \delta([\tilde{P}, \tilde{F}] \cdot [\tilde{Q}]), \dim (\tilde{P}) + \dim (\tilde{Q}) = n + 1, \) and \( \dim (\tilde{Q}) > 0. \) These elements are of types (i) and (iii) respectively in A.10. Also, corresponding to the elements of the form \( \delta([\tilde{P}, \tilde{F}] \cdot [\tilde{Q}]) \in \text{kernel \( (h_*) \)}, \) where \( \tilde{P} \) and \( \tilde{Q} \) are \( \mathbb{Z}/2 \)-manifolds, we include the elements \( i([\tilde{P}, \tilde{F}] \cdot [\tilde{Q}]) \) in the set \( \{x_i\} \subset \text{kernel \( (h_*) \)). \) These elements are of type (ii) in A.10.

Finally, suppose \( [M, f] \cdot [N] \in \text{kernel \( (h_*) \) \cap (H_*(X, \mathbb{Z}) \otimes \Omega_*(pt))}, \) and \( 2' [M, f] \cdot [N] = 0. \) We consider two cases: first, \( 2[N] = 0 \in \Omega_*(pt) \) and, secondly, \( 2' [M, f] = 0 \in H_*(X, \mathbb{Z}) \subset \Omega_*(X). \) It is easy to see these two cases suffice since \( \Omega_*(pt) \) is a free group plus 2-torsion. In the first case, choose \( \tilde{N} \) a \( \mathbb{Z}/2 \)-manifold with \( \delta \tilde{N} = N. \) Then \( [M, f] \cdot [N] = \delta([M, f] \cdot [N]), \) hence we can add the elements \( i([M, f] \cdot [\tilde{N}]) \) to the set \( \{x_i\} \) in A.10 to the set \( \{x_i\}. \) In the second case, let \( [M, f] = \delta(M, f) \cdot [\tilde{N}], \) where \( \tilde{M} \) is a \( \mathbb{Z}/2 \)-manifold. Then \( [M, f] \cdot [N] = \delta(M, f) \cdot [N], \) hence we can add the elements \( [\tilde{M}, \tilde{f}] \cdot [\tilde{N}] \) of type (i) in A.10 to the set \( \{x_i\}. \) This completes the proof, since now our set \( \{x_i\} \) has the required property \( \delta[x_i] = \text{kernel \( (h_*) \) \cap kernel \( (2') \)). \)

**Proposition A.11.** Graded \( \mathbb{Z}/2' \)-cohomology classes \( z_* \in H^*(X, Z/2') \) correspond bijectively with homomorphisms \( \phi_*: \Omega_*(X, Z/2') \to Z/2' \) which satisfy

(i) \( \phi_*([M, f] \cdot [N]) = \phi_*([M, f]) \cdot \text{index} (N) \subset Z/2', \) where \( [M, f] \in \Omega_*(X, Z/2') \) and \( [N] \in \Omega_*(pt), \)

(ii) \( \phi_* (i([\tilde{M}, \tilde{f}] \cdot [\tilde{N}])) = \phi^* (i([M, f])) \cdot \text{index} (\tilde{N}) \in Z/2 \subset Z/2', \) where \( [\tilde{M}, \tilde{f}] \in \Omega_*(X, \mathbb{Z}/2), \) \( [\tilde{N}] \in \Omega_*(pt, \mathbb{Z}/2), \) and

(iii) \( \phi_* (\rho_* \delta([\tilde{P}, \tilde{F}] \cdot [\tilde{Q}])) = \phi^* (\rho_* \delta([\tilde{P}, \tilde{F}] \cdot [\tilde{Q}])) \cdot \text{index} (\tilde{Q}) \in Z/2 \subset Z/2', \) where \( [\tilde{P}, \tilde{F}] \in \Omega_*(X, \mathbb{Z}/2) \) and \( [\tilde{Q}] \in \Omega_*(pt, \mathbb{Z}/2). \) The defining equation is

\[
\phi_* ([M, f]) = \left\langle \rho_* L(M) \cdot f^* \left( \sum_{l=0}^{\infty} z_{s-l} \right), [M] \right\rangle \in Z/2'.
\]

**Proof.** This follows easily from Lemma A.10, the discussion in the first paragraph of Case \( Z/2', \) and properties of the class \( L \in H^*(BSO, \mathbb{Z}[[u]]). \)
REMARK A.12. If \( r = 1 \), Proposition A.11 is simply Proposition A.3, since \( \rho_1 L = V^r \in H^r(\text{BSO}, \mathbb{Z}/2) \), and since, for \( \mathbb{Z}/2 \)-manifolds, index \( (N) = \chi(N) \in \mathbb{Z}/2 \).

REMARK A.13. Given \( \phi_*: \Omega_*(X, \mathbb{Z}/2^r) \to \mathbb{Z}/2^r \), consider the homomorphisms for \( s \geq 1 \),

\[
\phi^s \rho_2 \delta: \Omega_{n+1}(X, \mathbb{Z}/2^r) \to \Omega_n(X) \to \Omega_n(X, \mathbb{Z}/2^r) \to \mathbb{Z}/2^r .
\]

If \( s \leq r \), image \( (\phi^s \rho_2 \delta) \subset Z/2^r \subset Z/2^r \). If \( s \geq r \), we compose \( \phi^s \rho_2 \delta \) with the inclusion \( Z/2^r \subset Z/2^s \). It is easy to see that this gives a commutative diagram

\[
\begin{array}{ccc}
\Omega_*(X) & \to & Q \\
\downarrow & & \downarrow \\
\Omega_*(X, \mathbb{Z}/2^r) & \overset{\phi_2}{\to} & \mathbb{Z}/2^\infty \\
\end{array}
\]

(A.14)

where \( Z/2^\infty = \lim_{s \to \infty} Z/2^r \) and \( \phi_2 = \lim (\phi^s \rho_2 \delta |_{\Omega_*(X, \mathbb{Z}/2^r)}). \) If \( \phi_*: \Omega_*(X, \mathbb{Z}/2^r) \to \mathbb{Z}/2^r \) satisfies the hypothesis of A.11 (hence gives classes \( z_n \in H^*(X, \mathbb{Z}/2^r) \), \( n \geq 0 \)), then it is not hard to prove that the diagram A.14 above satisfies the hypothesis of A.6. The point is, the product formulae A.11(i) and (iii) imply the product formula A.6(ii). Thus diagram A.14 gives torsion \( \mathbb{Z}/2 \)-classes \( \kappa_{n+1} \in H^{s+1}(X, \mathbb{Z}/2) \). It is clear that \( \kappa_{n+1} = \beta z_n \) where \( \beta \) is the Bockstein for the coefficient sequence

\[
0 \to Z_{(2)}^{2r} \overset{2r}{\to} Z_{(2)}^r \to Z/2^r \to 0 .
\]

REMARK A.15. In the cases \( \mathbb{Z}/2, \mathbb{Q}, \) and \( \mathbb{Z}/(2) \) above, all the theorems stated remain true if smooth bordism is replaced by PL-bordism. (In Case \( \mathbb{Z}/(2) \), one uses the result of [15] that \( L \in H^\infty(\text{BSO}, \mathbb{Z}/(2)) \) extends to a canonical class \( L \in H^\infty(\text{BSPL}, \mathbb{Z}/(2)) \).) The case \( Z/2^r \) is somewhat more complicated, since \( \Omega^\infty_*(pt) \) contains torsion of order \( 2^r \), all \( s \geq 1 \). Thus kernel \( (h^\infty_*(2^r): \Omega^\infty_*(X, Z/2^r) \to H_*(X, Z/2^r)) \) is complicated. However, one can show the following analog of Lemma A.10.

**Lemma A.10(PL).** Kernel \( (h^\infty_*(2^r)) \subset \Omega^\infty_*(X, Z/2^r) \) is generated by

(i) images of products \( i([M, f] \cdot [N]) \), where \( [M, f] \in \Omega^\infty_*(X, Z/2^r) \), \( [N] \in \Omega^\infty_*(pt, Z/2^r) \), and \( \dim (N) > 0, s \leq r \), and \( i: Z/2^r \to Z/2^r \) the inclusion.

(ii) \( Z/r^r \)-reductions of Bocksteins of products, \( \rho_2 \delta([P, F] \cdot [Q]) \), where \( [P, F] \in \Omega^\infty_*(X, Z/2^r), [Q] \in \Omega^\infty_*(pt, Z/2^r) \), and \( \dim (Q) > 0, \) and \( s \leq r \).

As a corollary, one obtains the following analog of Proposition
A.11.

PROPOSITION A.11(PL). Graded \(Z/2\text{-}\)cohomology classes \(z_\ast \in H^\ast(X, Z/2)\) correspond bijectively with homomorphisms

\[
\phi_\ast: \Omega^\ast_{PL}(X, Z/2') \longrightarrow Z/2',
\]

which satisfy

(i) \(\phi_\ast(i([M, f]\cdot[N])) = \phi_\ast(i[M, f]) \cdot \text{index}(N) \in Z/2' \subset Z/2',\) where \([M, f] \in \Omega^\ast_{PL}(X, Z/2'), [N] \in \Omega^*_{PL}(pt, Z/2'), s \leq r.\)

(ii) \(\phi_\ast(\rho_s\delta([P, F]\cdot[Q])) = \phi_\ast(\rho_s\delta[P, F]) \cdot \text{index}(Q) \in Z/2' \subset Z/2',\) where \([P, F] \in \Omega^\ast_{PL}(X, Z/2'), Q \in \Omega^*_{PL}(pt, Z/2'), s \leq r.\)

The defining equation is

\[
\phi_\ast([M, f]) = \left< \rho_s L(M) \cdot f^\ast \left( \sum_{i=0}^{n} z_{n-i} \right), [M] \right> \in Z/2'.
\]
