# DELTA INVARIANTS OF SINGULAR DEL PEZZO SURFACES 

IVAN CHELTSOV, JIHUN PARK, CONSTANTIN SHRAMOV

#### Abstract

We estimate $\delta$-invariants of some singular del Pezzo surfaces with quotient singularities, which we studied ten years ago. As a result, we show that each of these surfaces admits an orbifold Kähler-Einstein metric.

All varieties are assumed to be complex, projective and normal unless otherwise stated.

## 1. Introduction

Let $S_{d}$ be a quasismooth and well-formed hypersurface in $\mathbb{P}\left(a_{0}, a_{1}, a_{2}, a_{3}\right)$ of degree $d$, where $a_{0} \leqslant a_{1} \leqslant a_{2} \leqslant a_{4}$. Then $S_{d}$ is given by a quasihomogeneous polynomial equation of degree $d$

$$
f(x, y, z, t)=0 \subset \mathbb{P}\left(a_{0}, a_{1}, a_{2}, a_{3}\right) \cong \operatorname{Proj}(\mathbb{C}[x, y, z, t])
$$

where $\operatorname{wt}(x)=a_{0}, \mathrm{wt}(y)=a_{1}, \mathrm{wt}(z)=a_{2}, \mathrm{wt}(t)=a_{3}$. Here, being quasismooth simply means that the above equation defines a singularity only at the origin in $\mathbb{C}^{4}$, which implies that $S_{d}$ has at most cyclic quotient singularities. On the other hand, being well-formed implies that

$$
K_{S_{d}} \sim_{\mathbb{Q}} \mathcal{O}_{\mathbb{P}\left(a_{0}, a_{1}, a_{2}, a_{3}\right)}\left(d-a_{0}-a_{1}-a_{2}-a_{3}\right)
$$

see Do82, Theorem 3.3.4], [IF00, 6.14].
Put $I=a_{0}+a_{1}+a_{2}+a_{3}-d$ and suppose that $I$ is positive. Then $S_{d}$ is a del Pezzo surfaces with at most quotient singularities. Such singular del Pezzo surfaces with orbifold Kähler-Einstein metrics drew attention from Riemannian geometers because they may lift to Sasakian-Einstein 5-manifolds through $S^{1}$-bundle structures. Through this passage, Boyer, Galicki and Nakamaye yielded a significant amount of examples towards classification of simply-connected SasakianEinstein 5-manifolds (see BGN03, BG08]).

In [P18, Paemurru presented an algorithm that produce the (infinite) list of all possibilities for the quintuple $\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)$ for every fixed $I \geqslant 1$. For $I=1$, this list has been found much earlier by Johnson and Kollár in JK01]. In this case, we have the following trichotomy:

- the surface $S_{d}$ is smooth and

$$
\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right) \in\{(1,1,1,1,3),(1,1,1,2,4),(1,1,2,3,6)\}
$$

- the surface $S_{d}$ is singular and

$$
\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)=(2,2 n+1,2 n+1,4 n+1,8 n+4)
$$

where $n$ is a positive integer;

- the surface $S_{d}$ is singular and $\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)$ is one of the following quintuples:

$$
\begin{gathered}
(1,2,3,5,10),(1,3,5,7,15),(1,3,5,8,16),(2,3,5,9,18), \\
(3,3,5,5,15),(3,5,7,11,25),(3,5,7,14,28),(3,5,11,18,36), \\
(5,14,17,21,56),(5,19,27,31,81),(5,19,27,50,100),(7,11,27,37,81), \\
(7,11,27,44,88),(9,15,17,20,60),(9,15,23,23,69),(11,29,39,49,127), \\
(11,49,69,128,256),(13,23,35,57,127),(13,35,81,128,256) .
\end{gathered}
$$

In JK01, Johnson and Kollár also proved the following result:
Theorem 1.1 ( JK01, Theorem 8]). Suppose that $S_{d}$ with $I=1$ is singular and the quintuple ( $\left.a_{0}, a_{1}, a_{2}, a_{3}, d\right)$ is not one of the following four quintuples:

$$
\begin{equation*}
(1,2,3,5,10),(1,3,5,7,15),(1,3,5,8,16),(2,3,5,9,18) \tag{1.2}
\end{equation*}
$$

Then $S_{d}$ admits an orbifold Kähler-Einstein metric.
Its proof uses the criterion given by the $\alpha$-invariant (for the definition, see [CS08, Definition 1.2]) of the surface $S_{d}$ [87, N90, DK01]. It says that $S_{d}$ admits an (orbifold) KählerEinstein metric if the inequality

$$
\begin{equation*}
\alpha\left(S_{d}\right)>\frac{2}{3} \tag{1.3}
\end{equation*}
$$

holds, where $\alpha\left(S_{d}\right)$ is the $\alpha$-invariant of the surface $S_{d}$. Indeed, Johnson and Kollár verified (1.3) in the case when $I=1$, the surface $S_{d}$ is singular, and the quintuple ( $\left.a_{0}, a_{1}, a_{2}, a_{3}, d\right)$ is not one of the four exceptions (1.2). Two of the four remaining cases (1.2) have been treated in [A02] by Araujo, who proved the following result:

Theorem 1.4 ( $\mathbf{( 1 0 2}$, Theorem 4.1]). In the following two cases:

- $\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)=(1,2,3,5,10)$,
- $\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)=(1,3,5,7,15)$ and the equation of $S_{d}$ contains $y z t$,
the inequality $\alpha\left(S_{d}\right)>\frac{2}{3}$ holds. In particular, $S_{d}$ admits an orbifold Kähler-Einstein metric.
If $\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)=(1,3,5,7,15)$ and the defining equation of the surface $S_{d}$ does not contain the monomial $y z t$, then $\alpha\left(S_{d}\right)=\frac{8}{15}<\frac{2}{3}$ by CPS10, Theorem 1.10], so that the criterion by the $\alpha$-invariant could not be applied.

We have dealt with the other two cases of (1.2) in [CPS10]. We succeeded in estimating their $\alpha$-invariants from below by large enough numbers for the criterion (1.3). To be precise, we proved the following result exactly ten years ago:

Theorem 1.5 ([CPS10, Theorem 1.10]). Suppose that $\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)=(1,3,5,8,16)$ or $(2,3,5,9,18)$. Then $\alpha\left(S_{d}\right)>\frac{2}{3}$. In particular, the surface $S_{d}$ admits an orbifold KählerEinstein metric.
Corollary 1.6. Suppose that $I=1$. Then $S_{d}$ admits an orbifold Kähler-Einstein metric except possibly the case when $\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)=(1,3,5,7,15)$ and the defining equation of the surface $S_{d}$ does not contain $y z t$.

In CPS10, we also intensively investigated the cases with $I \geqslant 2$. In fact, the problem of existence of an orbifold Kähler-Einstein metric on the surface $S_{d}$ with $I \geqslant 2$ was first studied by Boyer, Galicki and Nakamaye in BGN03. They observed that the criterion (1.3) cannot be applied to $S_{d}$ in the case when $I \geqslant \frac{3}{2} a_{0}$, since $\alpha\left(S_{d}\right) \leqslant \frac{a_{0}}{I}$. Moreover, in the case when $2 \leqslant I<\frac{3}{2} a_{0}$, they obtained the following classification result.

Theorem 1.7 ([BGN03, Theorem 4.5],[CS13, Theorem 1.10]). Suppose that $2 \leqslant I<\frac{3}{2} a_{0}$. Then we have the following trichotomy:
(1) there is a non-negative integer $k<I$ and a positive integer $a \geqslant I+k$ such that

$$
\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)=(I-k, I+k, a, a+k, 2 a+k+I) ;
$$

(2) the quintuple ( $\left.a_{0}, a_{1}, a_{2}, a_{3}, d\right)$ belongs to one of the following infinite series:

- $(3,3 n, 3 n+1,3 n+1,9 n+3)$,
- $(3,3 n+1,3 n+2,3 n+2,9 n+6)$,
- $(3,3 n+1,3 n+2,6 n+1,12 n+5)$,
- $(3,3 n+1,6 n+1,9 n, 18 n+3)$,
- $(3,3 n+1,6 n+1,9 n+3,18 n+6)$,
- $(4,2 n+3,2 n+3,4 n+4,8 n+12)$,
- $(4,2 n+3,4 n+6,6 n+7,12 n+18)$,
- $(6,6 n+3,6 n+5,6 n+5,18 n+15)$,
- $(6,6 n+5,12 n+8,18 n+9,36 n+24)$,
- $(6,6 n+5,12 n+8,18 n+15,36 n+30)$,
- $(8,4 n+5,4 n+7,4 n+9,12 n+23)$,
- $(9,3 n+8,3 n+11,6 n+13,12 n+35)$,
where $n$ is a positive integer;
(3) the quintuple ( $\left.a_{0}, a_{1}, a_{2}, a_{3}, d\right)$ lies in the sporadic set
$(2,3,4,7,14),(3,4,5,10,20),(3,4,6,7,18),(3,4,10,15,30),(5,13,19,22,57)$,
$(5,13,19,35,70),(6,9,10,13,36),(7,8,19,25,57),(7,8,19,32,64)$, $(9,12,13,16,48),(9,12,19,19,57),(9,19,24,31,81),(10,19,35,43,105)$, $(11,21,28,47,105),(11,25,32,41,107),(11,25,34,43,111),(11,43,61,113,226)$, $(13,18,45,61,135),(13,20,29,47,107),(13,20,31,49,111),(13,31,71,113,226)$, $(14,17,29,41,99),(5,7,11,13,33),(5,7,11,20,40),(11,21,29,37,95)$,
$(11,37,53,98,196),(13,17,27,41,95),(13,27,61,98,196),(15,19,43,74,148)$, $(9,11,12,17,45),(10,13,25,31,75),(11,17,20,27,71),(11,17,24,31,79)$,
$(11,31,45,83,166),(13,14,19,29,71),(13,14,23,33,79),(13,23,51,83,166)$,
$(11,13,19,25,63),(11,25,37,68,136),(13,19,41,68,136),(11,19,29,53,106)$, $(13,15,31,53,106),(11,13,21,38,76),(3,7,8,13,29),(3,10,11,19,41)$, $(5,6,8,9,24),(5,6,8,15,30),(2,3,4,5,12),(7,10,15,19,45)$, $(7,18,27,37,81),(7,15,19,32,64),(7,19,25,41,82),(7,26,39,55,117)$.

Boyer, Galicki and Nakamaye proved that $\alpha\left(S_{d}\right) \leqslant \frac{2}{3}$ in the case when

$$
\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)=(I-k, I+k, a, a+k, 2 a+k+I)
$$

for some non-negative integer $k<I$ and some positive integer $a \geqslant I+k$. Moreover, they estimated the $\alpha$-invariants for some infinite series in Theorem 1.7(2), and for many sporadic cases in Theorem 1.7(3). In CS13, CPS10, we evaluated the $\alpha$-invariants for all infinite series in Theorem 1.7(2) and all sporadic cases in Theorem 1.7(3). This gave
Theorem 1.8 (CS13, CPS10). Suppose that $\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)$ is one of the quintuples listed in Theorem 1.7(2),(3). Then $\alpha\left(S_{d}\right)>\frac{2}{3}$ except for the following six cases:
(1) $\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)=(2,3,4,5,12)$ and equation of $S_{d}$ does not contain $y z t$;
(2) $\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)=(7,10,15,19,45)$;
(3) $\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)=(7,18,27,37,81)$;
(4) $\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)=(7,15,19,32,64)$;
(5) $\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)=(7,19,25,41,82)$;
(6) $\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)=(7,26,39,55,117)$.

Meanwhile, since 2010 we have witnessed dramatic developments in the study of the Yau-Tian-Donaldson conjecture concerning the existence of Kähler-Einstein metrics on Fano manifolds and stability. The challenge to the conjecture has been highlighted by Chen, Donaldson, Sun and Tian who have completed the proof for the case of Fano manifolds with anticanonical polarisations CDS15, T15. Following this celebrated achievement, useful technologies have been introduced to determine whether given Fano varieties are Kähler-Einstein or not, via the theorem of Chen-Donaldson-Sun and Tian. For instance, Fujita improved the criterion (1.3) for smooth Fano varieties. In particular, his [F18, Theorem 1.2] shows that if the surface $S_{d}$ is smooth and $\alpha\left(S_{d}\right) \geqslant \frac{2}{3}$, then $S_{d}$ admits a Kähler-Einstein metric.

Corollary 1.9 ([90]). Suppose that $I=1$ and $S_{d}$ is smooth. Then $S_{d}$ is Kähler-Einstein.
Proof. By [C08, Theorem 1.7], one has $\alpha\left(S_{d}\right) \geqslant \frac{2}{3}$. Use [F18, Theorem 1.2].
Recently Fujita and Odaka introduced a new invariant of Fano varieties, which they called $\delta$-invariant (for the definition, see [F018, Definition 1.2]), that serves as a strong criterion for uniform K-stability (see [FO18]).
Theorem 1.10 ( FO18, BJ17]). Let $X$ be a Fano variety with at most Kawamata log terminal singularities. Then $X$ is uniformly K-stable if and only if $\delta(X)>1$.

This powerful tool has been practiced for smooth del Pezzo surfaces in PW18, CZ18, and therein its effectiveness has been presented. Around the same time, Li, Tian and Wang proved in LTW17 that the result of Chen, Donaldson, Sun and Tian also holds for some singular Fano varieties. In particular, it holds for del Pezzo surfaces with quotient singularities. This gives

Theorem 1.11. If $\delta\left(S_{d}\right)>1$, then $S_{d}$ admits an (orbifold) Kähler-Einstein metric.
Now we are strongly reinforced by these new technologies, so that we could complete the assertions of Corollary 1.6 and Theorem 1.8 in terms of the $\delta$-invariants and existence of KählerEinstein metrics as follows:

Theorem 1.12. Suppose that $I=1$ or $\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)$ is one of the quintuples listed in Theorem 1.7(2),(3). Then

$$
\delta\left(S_{d}\right) \geqslant \frac{65}{64} .
$$

In particular, the surface $S_{d}$ admits an orbifold Kähler-Einstein metric.
This theorem is the main result of the present paper. By [BJ17, Theorem B], we know that

$$
\begin{equation*}
\delta\left(S_{d}\right) \geqslant \frac{3}{2} \alpha\left(S_{d}\right) \tag{1.13}
\end{equation*}
$$

Therefore, it follows from [CPS10, Theorem 1.10] and [PW18, Main Theorem] that to prove Theorem 1.12, we have only to show that $\delta\left(S_{d}\right) \geqslant \frac{65}{64}$ for the surfaces $S_{d}$ in $\mathbb{P}\left(a_{0}, a_{1}, a_{2}, a_{3}\right)$ of types:
(1) $\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)=(1,3,5,7,15)$ and the equation of $S_{d}$ contains $y z t$;
(2) $\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)=(2,3,4,5,12)$ and equation of $S_{d}$ does not contain $y z t$;
(3) $\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)=(7,10,15,19,45)$;
(4) $\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)=(7,18,27,37,81)$;
(5) $\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)=(7,15,19,32,64)$;
(6) $\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)=(7,19,25,41,82)$;
(7) $\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)=(7,26,39,55,117)$.

According to the similarity of their proofs, we handle these seven types of del Pezzo surfaces in three cases as follows:

Case A. $\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)=(1,3,5,7,15)$ and the equation of $S_{d}$ contains $y z t$;
$\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)=(2,3,4,5,12)$ and equation of $S_{d}$ does not contain $y z t$;
Case B. $\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)=(7,15,19,32,64)$;
$\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)=(7,19,25,41,82)$;
Case C. $\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)=(7,10,15,19,45)$;
$\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)=(7,18,27,37,81) ;$ $\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)=(7,26,39,55,117)$.
We will handle each of these cases separately in Sections 3 (4) and 5, respectively. In Section 2. we will present some results that will be used in the proof of Theorem 1.12,

It would be interesting to study the problem of existence of an orbifold Kähler-Einstein metric on $S_{d}$ in the remaining cases with $\alpha\left(S_{d}\right) \leqslant \frac{2}{3}$. In some of these cases, the del Pezzo surface $S_{d}$ is indeed not Kähler-Einstein. For instance, the surface $S_{d}$ does not admit an orbifold KählerEinstein metric in the case when

$$
I>3 a_{0}
$$

This follows from the obstruction found by Gauntlett, Martelli, Sparks, Yau GMSY07. On the other hand, we expect the following to be true:

Conjecture 1.14. If $I=2$, then $S_{d}$ admits an orbifold Kähler-Einstein metric.
We believe that this conjecture can be proven using a similar approach to the one we use in the proof of Theorem 1.12, Note also that the list of all possible values of the quintuple $\left(a_{0}, a_{1}, a_{2}, a_{3}, d\right)$ with $I=2$ is known. It is contained in CS13, Corollary 1.14] and [P18, Table 2]. Thus, one can prove Conjecture 1.14 by case by case analysis. In fact, in some of these cases we already know that $\delta\left(S_{d}\right) \geqslant \frac{65}{64}$ by Theorem 1.12.

Acknowledgements. We started to work on this paper during our stay at the Erwin Schrödinger International Institute for Mathematics and Physics in Vienna in August 2018. ## 2. BASIC TOOLS

Let $S$ be a surface with at most cyclic quotient singularities, let $C$ be an irreducible reduced curve on $S$, let $P$ be a point of the curve $C$, and let $D$ be an effective $\mathbb{R}$-divisor on the surface $S$. In this section, we present a few of well-known (local and global) results that will be used in the proof of Theorem 1.12, We start with
Lemma 2.1 (K97). Suppose that $P$ is a smooth point of the surface $S$, and the singularities of the $\log$ pair $(S, D)$ are not $\log$ canonical at $P$. Then $_{\operatorname{mult}_{P}(D)>1 .}$

This immediately implies

Corollary 2.2. If $P$ is a smooth point of the surface $S$, the $\log$ pair $(S, D)$ is not $\log$ canonical at $P$, and $C$ is not contained in the support of the divisor $D$, then $D \cdot C>1$.

To state an analogue of this result in the case when $S$ is singular at $P$, recall that $S$ has a cyclic quotient singularity of type $\frac{1}{n}(a, b)$ at the point $P$, where $a$ and $b$ are coprime positive integers that are also coprime to $n$. Thus, if $n=1$, then $P$ is a smooth point of the surface $S$. For $n>1$, Corollary 2.2 can be generalized as follows:
Lemma 2.3. Suppose that the $\log$ pair $(S, D)$ is not $\log$ canonical at $P$, and $C$ is not contained in the support of the divisor $D$. Then $D \cdot C>\frac{1}{n}$.
Proof. This follows from [CPS10, Lemma 2.2] and CPS10, Lemma 2.3], cf. [BMO].
In general, the curve $C$ may be contained in the support of the divisor $D$. Thus, we write

$$
D=a C+\Delta,
$$

where $a$ is a non-negative real number, and $\Delta$ is an effective $\mathbb{R}$-divisor on $S$ whose support does not contain the curve $C$. Then we have the following useful result:
Lemma 2.4. Suppose that $a \leqslant 1$, the surface $S$ is smooth at the point $P$, the curve $C$ is also smooth at $P$, and the $\log$ pair $(S, D)$ is not $\log$ canonical at $P$. Then

$$
C \cdot \Delta \geqslant(C \cdot \Delta)_{P}>1,
$$

where $(C \cdot \Delta)_{P}$ is the local intersection number of $C$ and $\Delta$ at $P$.
Proof. This is a special case of a much more general result, known as the inversion of adjunction (see [S93, P01).

The inversion of adjunction also holds for singular varieties. In our two-dimensional case, it can be stated as follows:
Lemma 2.5. Suppose that $a \leqslant 1$, the $\log$ pair $(S, C)$ is purely $\log$ terminal at $P$, and the $\log$ pair $(S, D)$ is not $\log$ canonical at $P$. Then

$$
C \cdot \Delta>\frac{1}{n}
$$

Proof. The required inequality follows from a more general version of the inverse of adjunction (see [593, P01]). See also the proof of [CPS10, Lemma 2.5].

By our assumption, the surface $S$ has a cyclic quotient singularity of type $\frac{1}{n}(a, b)$ at the point $P$. Thus, locally near $P$, the surface $S$ is a quotient of $\mathbb{C}^{2}$ by the group $\mathbb{Z}_{n}$ that acts on $\mathbb{C}^{2}$ as

$$
(x, y) \mapsto\left(\omega^{a} x, \omega^{b} y\right)
$$

where $\omega$ is a primitive $n$th root of unity. We can consider $x$ and $y$ as weighted coordinates around the point $P$.
Remark 2.6. The pair $(S, C)$ has purely $\log$ terminal singularity at $P$ if and only if $C$ is given by $x=0$ or $y=0$ for an appropriate choice of weighted coordinates $x$ and $y$. This follows from P01, Theorem 2.1.2], see also K97, § 9.6]. Geometrically, this means that $C$ is smooth at $P$, and its proper transform on the minimal resolution of singularities of the singular point $P$ intersects the tail curve in the chain of exceptional curves. If $(S, C)$ has purely log terminal singularities, then

$$
\left(K_{S}+C\right) \cdot C=-2+\sum_{O \in C} \frac{n_{O}-1}{n_{O}}
$$

where we assume that $S$ has a cyclic quotient singularity of index $n_{O}$ at the point $O$.

Let $f: \widetilde{S} \rightarrow S$ be the weighted blow up of the point $P$ with $\operatorname{wt}(x)=a$ and $\operatorname{wt}(y)=b$, and let $E$ be the exceptional curve of the morphism $f$. Then $\widetilde{S}$ has at most cyclic quotient singularities, one has $E \cong \mathbb{P}^{1}$, and the $\log$ pair $(\widetilde{S}, E)$ has purely $\log$ terminal singularities. Moreover, the curve $E$ has at most two singular points of the surface $\widetilde{S}$. One of then is a singular point of type $\frac{1}{a}(n,-b)$, and another is a singular point of type $\frac{1}{b}(-a, n)$. Furthermore, we have

$$
K_{\widetilde{S}} \sim_{\mathbb{Q}} f^{*}\left(K_{S}\right)+\frac{a+b-n}{n} E .
$$

If the curve $C$ is locally given by $x=0$ near the point $P$, then

$$
\widetilde{C} \sim_{\mathbb{Q}} f^{*}(C)-\frac{a}{n} E,
$$

where $\widetilde{C}$ is the proper transform of the curve $C$ on the surface $\widetilde{S}$. For more properties of weighted blow ups and their defining equations, see [P01, Section 3] or [BMO].

Denote by $\widetilde{D}$ the proper transform of the divisor $D$ via $f$. Then

$$
\widetilde{D} \sim_{\mathbb{R}} f^{*}(D)-m E
$$

for some non-negative rational number $m$. If $C$ is not contained in the support of the divisor $D$, we can estimate $m$ using

$$
0 \leqslant \widetilde{D} \cdot \widetilde{C}=\left(f^{*}(D)-m E\right) \cdot \widetilde{C}=D \cdot C-m E \cdot \widetilde{C}
$$

where $D \cdot C$ and $E \cdot \widetilde{C}$ can be computed in every case. Note that

$$
K_{\widetilde{S}}+\widetilde{D}+\left(m-\frac{a+b-n}{n}\right) E \sim_{\mathbb{R}} f^{*}\left(K_{S}+D\right) .
$$

This implies
Proposition 2.7. The $\log$ pair $(S, D)$ is $\log$ canonical at $P$ if and only if the $\log$ pair

$$
\left(\widetilde{S}, \widetilde{D}+\left(m-\frac{a+b-n}{n}\right) E\right)
$$

is $\log$ canonical along the curve $E$.
So far, we considered only local properties of the divisor $D$ on the surface $S$. These properties will be used later to prove Theorem 1.12. However, the nature of this theorem is global, so that we will need one global result that is due to Fujita and Odaka. To state it, we remind the reader of what the volume $\operatorname{vol}(D)$ of the $\mathbb{R}$-divisor $D$ is. If $D$ is a Cartier divisor, then its volume is simply the number

$$
\operatorname{vol}(D)=\limsup _{k \in \mathbb{N}} \frac{h^{0}\left(\mathcal{O}_{S}(k D)\right.}{k^{2} / 2!},
$$

where the limsup can be replaced by limit (see [L04, Example 11.4.7]). Likewise, if $D$ is a $\mathbb{Q}$-divisor, we can define its volume using the identity

$$
\operatorname{vol}(D)=\frac{\operatorname{vol}(\lambda D)}{\lambda^{2}}
$$

for an appropriate positive rational number $\lambda$. One can show that the volume $\operatorname{vol}(D)$ only depends on the numerical equivalence class of the divisor $D$. Moreover, the volume function can be continuously extended to $\mathbb{R}$-divisors (see $[\mathbf{L 0 4}$ for details).

If $D$ is not pseudoeffective, then $\operatorname{vol}(D)=0$. If $D$ is pseudoeffective, its volume can be computed using its Zariski decomposition [P03, BKS04. Namely, if $D$ is pseudoeffective, then there exists a nef $\mathbb{R}$-divisor $N$ on the surface $S$ such that

$$
D \sim_{\mathbb{R}} N+\sum_{i=1}^{r} a_{i} C_{i}
$$

where each $C_{i}$ is an irreducible curve on $S$ with $N \cdot C_{i}=0$, each $a_{i}$ is a non-negative real number, and the intersection form of the curves $C_{1}, \ldots, C_{r}$ is negative definite. Such decomposition is unique, and it follows from BKS04, Corollary 3.2] that

$$
\begin{equation*}
\operatorname{vol}(D)=\operatorname{vol}(N)=N^{2} . \tag{2.8}
\end{equation*}
$$

Recall that $D=a C+\Delta$, where $a$ is a non-negative real number, and $\Delta$ is an effective divisor whose support does not contain the curve $C$. Let

$$
\tau=\sup \left\{x \in \mathbb{R}_{>0} \mid D-x C \text { is pseudoeffective }\right\} .
$$

Then $a \leqslant \tau$. However, to prove Theorem 1.12, we have to find a better bound for $a$ under an additional assumption that $D$ is an ample $\mathbb{Q}$-divisor of $k$-basis type for $k \gg 1$ (for the definition, see [FO18, Definition 1.1] and the proof of Theorem 2.9 below). One such estimate is given by the following very special case of [FO18, Lemma 2.2].

Theorem 2.9. Suppose that $D$ is a big $\mathbb{Q}$-divisor of $k$-basis type for $k \gg 1$. Then

$$
a \leqslant \frac{1}{D^{2}} \int_{0}^{\tau} \operatorname{vol}(D-x C) d x+\epsilon_{k}
$$

where $\epsilon_{k}$ is a small constant depending on $k$ such that $\epsilon_{k} \rightarrow 0$ as $k \rightarrow \infty$.
Proof. Let us give a sketch of the proof that shows the nature of the required bound. First, recall from [FO18] that being $k$-basis type simply means that

$$
D=\frac{1}{k d_{k}} \sum_{i=1}^{d_{k}}\left\{s_{i}=0\right\},
$$

where $d_{k}=h^{0}\left(S, \mathcal{O}_{S}(k D)\right)$ and $s_{1}, \ldots, s_{d_{k}}$ are linearly independent sections in $H^{0}\left(S, \mathcal{O}_{S}(k D)\right)$. Here, we assume that $k D$ is a Cartier divisor and $k \gg 0$.

Let $M$ be a positive rational number such that $M \geqslant \tau$. We may assume that $k M$ is an integer. Then there is a filtration of vector spaces

$$
\begin{aligned}
& 0=H^{0}\left(S, \mathcal{O}_{S}(k D-(k M+1) C)\right) \subseteq H^{0}\left(S, \mathcal{O}_{S}(k D-k M C)\right) \subseteq \\
& \subseteq H^{0}\left(S, \mathcal{O}_{S}(k D-(k M-1) C)\right) \subseteq \ldots \subseteq H^{0}\left(S, \mathcal{O}_{S}(k D-3 C)\right) \subseteq \\
& \quad \subseteq H^{0}\left(S, \mathcal{O}_{S}(k D-2 C)\right) \subseteq H^{0}\left(S, \mathcal{O}_{S}(k D-C)\right) \subseteq H^{0}\left(S, \mathcal{O}_{S}(k D)\right)
\end{aligned}
$$

Let $r_{i}=h^{0}\left(S, \mathcal{O}_{S}(k D-i C)\right)$. Then

$$
0=r_{k M+1} \leqslant r_{k M} \leqslant r_{k M-1} \leqslant \ldots \leqslant r_{3} \leqslant r_{2} \leqslant r_{1} \leqslant r_{0}=d_{k} .
$$

Since the sections $s_{1}, \ldots, s_{d_{k}}$ are linearly independent, we see that at most $r_{1}$ of them are contained in

$$
H^{0}\left(S, \mathcal{O}_{S}(k D-C)\right.
$$

Among them at most $r_{2}$ are contained in $H^{0}\left(S, \mathcal{O}_{S}(k D-2 C)\right)$. Among them at most $r_{3}$ are contained in $H^{0}\left(S, \mathcal{O}_{S}(k D-3 C)\right)$ etc. Finally, at most $r_{k M}$ sections among $s_{1}, \ldots, s_{d_{k}}$ are contained in

$$
H^{0}\left(S, \mathcal{O}_{S}(k D-k M C)\right.
$$

and there are no sections in $H^{0}\left(\mathcal{O}_{S}(k D-(k M+1) C)=0\right.$. Then

- at most $r_{1}$ sections among $s_{1}, \ldots, s_{d_{k}}$ vanish at $C$;
- at most $r_{2}$ sections among $s_{1}, \ldots, s_{d_{k}}$ vanish at $C$ with order $\geqslant 2$;
- at most $r_{3}$ sections among $s_{1}, \ldots, s_{d_{k}}$ vanish at $C$ with order $\geqslant 3$;
- ...
- at most $r_{k M-1}$ sections among $s_{1}, \ldots, s_{d_{k}}$ vanish at $C$ with order $\geqslant k M-1$;
- at most $r_{k M}$ sections among $s_{1}, \ldots, s_{d_{k}}$ vanish at $C$ with order $k M$;
- no sections among $s_{1}, \ldots, s_{d_{k}}$ vanish at $C$ with order $\geqslant k M+1$.

This immediately implies that the the order of vanishing of the product $s_{1} \cdot s_{2} \cdot s_{3} \cdot \ldots \cdot s_{d_{n}}$ at the curve $C$ is at most

$$
\begin{aligned}
& k M r_{k M}+(k M-1)\left(r_{k M-1}-r_{k M}\right)+(k M-2)\left(r_{k M-2}-r_{k M-1}\right)+\ldots \\
& \ldots+4\left(r_{4}-r_{5}\right)+3\left(r_{3}-r_{4}\right)+2\left(r_{2}-r_{3}\right)+\left(r_{1}-r_{2}\right)=\sum_{i=1}^{k M} r_{i} .
\end{aligned}
$$

Then we have

$$
a \leqslant \frac{r_{1}+r_{2}+\ldots+r_{k M-1}+r_{k M}}{k r_{0}}
$$

As $k \rightarrow \infty$, the right hand side in this inequality goes to

$$
\frac{1}{D^{2}} \int_{0}^{\tau} \operatorname{vol}(D-x C) d x
$$

which gives the bound on $a$. For a detailed proof, we refer the reader to [FO18.
Corollary 2.10. Suppose that $D$ is a big $\mathbb{Q}$-divisor of $k$-basis type for $k \gg 1$, and

$$
C \sim_{\mathbb{Q}} \mu D
$$

for some positive rational number $\mu$. Then

$$
a \leqslant \frac{1}{3 \mu}+\epsilon_{k},
$$

where $\epsilon_{k}$ is a small constant depending on $k$ such that $\epsilon_{k} \rightarrow 0$ as $k \rightarrow \infty$.
Proof. Using Theorem [2.9, we get

$$
a \leqslant \frac{1}{D^{2}} \int_{0}^{\infty} \operatorname{vol}(D-\lambda C) d \lambda+\epsilon_{k}
$$

where $\epsilon_{k}$ is a small constant depending on $k$ such that $\epsilon_{k} \rightarrow 0$ as $k \rightarrow \infty$. But

$$
\int_{0}^{\infty} \operatorname{vol}(D-\lambda C) d \lambda=\int_{0}^{\infty} \operatorname{vol}((1-\lambda \mu) D) d \lambda=D^{2} \int_{0}^{\frac{1}{\mu}}(1-\lambda \mu)^{2} d \lambda=\frac{D^{2}}{3 \mu}
$$

This implies the assertion.

## 3. Case A

In this section, we consider two types of quasismooth hypersurfaces as follows:

- $S_{15}$ : a quasismooth hypersurface in $\mathbb{P}(1,3,5,7)$ of degree 15 ;
- $S_{12}$ : a quasismooth hypersurface in $\mathbb{P}(2,3,4,5)$ of degree 12 .

By suitable coordinate changes, $S_{15}$ may be assumed to be given by

$$
\begin{aligned}
& z^{3}+y^{5}+x t^{2}+b_{1} y z t+b_{2} x y^{3} z+b_{3} x^{2} y z^{2}+b_{4} x^{2} y^{2} t+ \\
& +b_{5} x^{3} z t+b_{6} x^{3} y^{4}+b_{7} x^{4} y^{2} z+b_{8} x^{5} z^{2}+b_{9} x^{5} y t+b_{10} x^{6} y^{3}+ \\
& \quad+b_{11} x^{7} y z+b_{12} x^{8} t+b_{13} x^{9} y^{2}+b_{14} x^{10} z+b_{15} x^{12} y+b_{16} x^{15}=0
\end{aligned}
$$

and $S_{12}$ by

$$
z\left(z-x^{2}\right)\left(z-\epsilon x^{2}\right)+y^{4}+x t^{2}+b_{1} y z t+b_{2} x y^{2} z+b_{3} x^{2} y t+b_{4} x^{3} y^{2}=0
$$

where $\epsilon(\epsilon \neq 0$ and $\epsilon \neq 1), b_{1}, b_{2}, b_{3}, b_{4}, b_{5}, b_{6}, b_{7}, b_{8}, b_{9}, b_{10}, b_{11}, b_{12}, b_{13}, b_{14}, b_{15}$ and $b_{16}$ are constants. Note that the surface $S_{15}$ has the only singular point at $O_{t}=[0: 0: 0: 1]$. Meanwhile, $S_{12}$ has exactly four singular points at $O_{x}=[1: 0: 0: 0], O_{t}=[0: 0: 0: 1]$, $Q_{1}=[1: 0: 1: 0]$ and $Q_{2}=[1: 0: \epsilon: 0]$.

In the sequel, we use $S$ for the surfaces $S_{15}$ and $S_{12}$ if properties or conditions are satisfies by both the surfaces.

Denote by $C_{x}$ the curve in $S$ cut out by the equation $x=0$. Then the curve $C_{x}$ is reduced and irreducible in both the cases. It is easy to check

$$
\begin{aligned}
& \operatorname{lct}\left(S_{15}, C_{x}\right)=\left\{\begin{array}{l}
1 \text { if } a_{1} \neq 0 \\
\frac{8}{15} \text { if } a_{1}=0
\end{array}\right. \\
& \operatorname{lct}\left(S_{12}, C_{x}\right)=\left\{\begin{array}{l}
1 \text { if } a_{1} \neq 0, \\
\frac{7}{12} \text { if } a_{1}=0,
\end{array}\right.
\end{aligned}
$$

where lct $\left(S, C_{x}\right)$ is the $\log$ canonical threshold of $C_{x}$ on $S$. Moreover, one has $\alpha(S)=\operatorname{lct}\left(S, C_{x}\right)$ by CPS10, Theorem 1.10], so that (1.13) gives

Corollary 3.1. If $b_{1} \neq 0$, then $\delta(S) \geqslant \frac{3}{2}$.
From now on, we suppose that $b_{1}=0$.
Proposition 3.2. Let $D$ be an effective $\mathbb{Q}$-divisor on $S$ such that

$$
D \sim_{\mathbb{Q}}-K_{S}
$$

Write $D=a C_{x}+\Delta$, where $a$ is a non-negative number, and $\Delta$ is an effective $\mathbb{Q}$-divisor on the surface $S$ whose support does not contain the curve $C_{x}$. Suppose also that $a \leqslant \frac{8}{21}$. Then the $\log$ pair $\left(S, \frac{6}{5} D\right)$ is $\log$ canonical.

Corollary 3.3. One has $\delta(S) \geqslant \frac{6}{5}$.
Proof. Let $D$ be a $\mathbb{Q}$-divisor of $k$-basis type divisor on $S$ with $k \gg 0$. Write $D=a C_{x}+\Delta$, where $a$ is a non-negative number, and $\Delta$ is an effective $\mathbb{Q}$-divisor on the surface $S$ whose support does not contain the curve $C_{x}$. By Corollary 2.10, we have $a \leqslant \frac{8}{21}$ for $k \gg 0$. Thus, the $\log$ pair $\left(S, \frac{6}{5} D\right)$ is $\log$ canonical for $k \gg 0$ by Proposition 3.2. This implies that $\delta(S) \geqslant \frac{6}{5}$ by Corollary 3.1 .

To prove Proposition 3.2. we fix an effective $\mathbb{Q}$-divisor $D$ on the surface $S$ such that

$$
D \sim_{\mathbb{Q}}-K_{S}
$$

Write $D=a C_{x}+\Delta$, where $a$ is a non-negative number, and $\Delta$ is an effective $\mathbb{Q}$-divisor on the surface $S$ whose support does not contain the curve $C_{x}$. Suppose also that $a \leqslant \frac{8}{21}$. Let us show that the $\log$ pair $\left(S, \frac{6}{5} D\right)$ is $\log$ canonical.

Lemma 3.4. The $\log$ pair $\left(S, \frac{6}{5} D\right)$ is $\log$ canonical outside $C_{x}$.
Proof. The required assertion follows from [CPS10, Lemma 2.7]. For convenience of the reader, let us give the detailed proof here. Let $P$ be a point in $S \backslash C_{x}$. Since $P \notin C_{x}$, there are complex numbers $c_{1}$ and $c_{2}$ such that $P$ satisfies the following system of equations:

$$
\begin{aligned}
& \left\{\begin{array}{l}
z+c_{1} x^{5}=0 \\
y+c_{2} x^{3}=0
\end{array} \text { for } S_{15} ;\right.
\end{aligned}\left\{\begin{array}{l}
y^{2}+c_{1} x^{3}=0 \\
z+c_{2} x^{2}=0 \quad \text { for } S_{12} .
\end{array}\right.
$$

Let $\mathcal{P}$ be the pencil of curves that is given by

$$
\begin{array}{ll}
\nu\left(z+c_{1} x^{5}\right)+\mu\left(y x^{2}+c_{2} x^{5}\right)=0 & \text { on } S_{15}, \\
\nu\left(y^{2}+c_{1} x^{3}\right)+\mu\left(z x+c_{2} x^{3}\right)=0 & \text { on } S_{12}
\end{array}
$$

for $[\nu: \mu] \in \mathbb{P}^{1}$. Then the base locus of the pencil $\mathcal{P}$ consists of finitely many points. Moreover, by construction, the point $P$ is one of them. Let $C$ be a general curve in $\mathcal{P}$. Then

$$
C \cdot D \leqslant \frac{5}{6}
$$

so that $\left(S, \frac{6}{5} D\right)$ is $\log$ canonical at $P$ by Corollary 2.2 if $P$ is a smooth point of the surface $S$. This verifies the statement for $S_{15}$.

For $S_{12}$, we suppose that $\left(S_{12}, \frac{6}{5} D\right)$ is not $\log$ canonical at $P$. Then $P$ must be one of the points $O_{x}, Q_{1}, Q_{2}$. Observe that the point $P$ belongs to the curve $C_{y}$ cut by $y=0$. Moreover, the curve $C_{y}$ is irreducible and the $\log$ pair $\left(S_{12}, \frac{6}{5} \cdot \frac{2}{3} C_{y}\right)$ is $\log$ canonical. Thus, it follows from [CS08, Remark 2.22] that there exists an effective $\mathbb{Q}$-divisor $D^{\prime}$ on the surface $S_{12}$ such that

$$
D^{\prime} \sim_{\mathbb{Q}}-K_{S_{12}},
$$

the $\log$ pair $\left(S_{12}, \frac{6}{5} D^{\prime}\right)$ is not $\log$ canonical at the point $P$, and the support of the divisor $D^{\prime}$ does not contain the curve $C_{y}$. However,

$$
D^{\prime} \cdot C_{y}=\frac{6}{10},
$$

which is impossible by Lemma 2.3 since $\left(S_{12}, \frac{6}{5} D^{\prime}\right)$ is not $\log$ canonical at the point $P$. This completes the proof for $S_{12}$.

Lemma 3.5. The $\log$ pair $\left(S, \frac{6}{5} D\right)$ is $\log$ canonical at a point in $C_{x} \backslash\left\{O_{t}\right\}$.
Proof. Let $P$ be a point in $C_{x} \backslash\left\{O_{t}\right\}$. Observe that $P$ is a smooth point of the surface $S$, and $C_{x}$ is smooth at the point $P$. Note also that $\frac{6}{5} a<1$. Thus, we can apply Lemma 2.4 to $\left(S, \frac{6}{5} D\right)$ and the curve $C_{x}$ at the point $P$. Indeed, since

$$
\left(C_{x} \cdot \Delta\right)_{P} \leqslant C_{x} \cdot \Delta=\frac{1-a}{7} \leqslant \frac{5}{6} \quad \text { on } S_{15}
$$

$$
\left(C_{x} \cdot \Delta\right)_{P} \leqslant C_{x} \cdot \Delta=\frac{1-2 a}{5} \leqslant \frac{5}{6} \quad \text { on } S_{12},
$$

the $\log$ pair $\left(S, \frac{6}{5} D\right)$ must be $\log$ canonical at $P$.
Note that $S_{15}$ (resp. $S_{12}$ ) has singularity of type $\frac{1}{7}(3,5)$ (resp. $\left.\frac{1}{5}(3,4)\right)$ at the point $O_{t}$. In the chart defined by $t=1$, the surface $S_{15}$ is given by

$$
\begin{aligned}
& z^{3}+y^{5}+x+b_{2} x y^{3} z+b_{3} x^{2} y z^{2}+b_{4} x^{2} y^{2}+ \\
& +b_{5} x^{3} z+b_{6} x^{3} y^{4}+b_{7} x^{4} y^{2} z+b_{8} x^{5} z^{2}+b_{9} x^{5} y+b_{10} x^{6} y^{3}+ \\
& \quad+b_{11} x^{7} y z+b_{12} x^{8}+b_{13} x^{9} y^{2}+b_{14} x^{10} z+b_{15} x^{12} y+b_{16} x^{15}=0,
\end{aligned}
$$

and $S_{12}$ by

$$
z\left(z-x^{2}\right)\left(z-\epsilon x^{2}\right)+y^{4}+x+a_{1} y z+a_{2} x y^{2} z+a_{3} x^{2} y+a_{4} x^{3} y^{2}=0 .
$$

Thus, in a neighborhood of the point $O_{t}$, we may regard $y$ and $z$ as local weighted coordinates with $\operatorname{wt}(y)=3$ and $\operatorname{wt}(z)=5$ for $S_{15}$ and with $\operatorname{wt}(y)=3$ and $\operatorname{wt}(z)=4$ for $S_{12}$.

Let $f: \widetilde{S} \rightarrow S$ be the weighted blow up at the singular point $O_{t}$ with weights $\operatorname{wt}(y)=3$, $\mathrm{wt}(z)=5$ for $S_{15}$ and with weights $\mathrm{wt}(y)=3, \operatorname{wt}(z)=4$ for $S_{12}$. Denote by $E$ the exceptional curve of the blow up $f$. Then

$$
\begin{aligned}
& K_{\widetilde{S}_{15}} \sim_{\mathbb{Q}} f^{*}\left(K_{S_{15}}\right)+\frac{1}{7} E \\
& K_{\widetilde{S}_{12}} \sim_{\mathbb{Q}} f^{*}\left(K_{S_{12}}\right)+\frac{2}{5} E .
\end{aligned}
$$

The surface $S$ has two singular points in $E$. One is a point of type $\frac{1}{3}(1,1)$, and the other is a singular point of type $\frac{1}{5}(1,1)$ on $\widetilde{S}_{15}\left(\frac{1}{4}(1,1)\right.$ on $\left.\widetilde{S}_{12}\right)$. Denote the former by $O_{3}$ and the latter by $O$. Observe that

$$
\begin{array}{ll}
E^{2}=-\frac{7}{15} & \text { on } \widetilde{S}_{15} \\
E^{2}=-\frac{5}{12} & \text { on } \widetilde{S}_{12}
\end{array}
$$

and $E \cong \mathbb{P}^{1}$.
Let $\widetilde{C}_{x}$ be the proper transform of the curve $C_{x}$ on the surface $\widetilde{S}$. Then

$$
\widetilde{C}_{x} \sim_{\mathbb{Q}} f^{*}\left(C_{x}\right)-c E \quad \text { for } S_{15},
$$

where $c=\frac{15}{7}$ for $S_{15}$ and $c=\frac{12}{5}$ for $S_{12}$, and the intersection $E \cap \widetilde{C}_{x}$ consists of a single point, which is different from $O_{3}$ and $O$. Note that the curves $E$ and $\widetilde{C}_{x}$ intersect transversally at the point $E \cap \widetilde{C}_{x}$.

Denote by $\widetilde{\Delta}$ be the proper transform of the $\mathbb{Q}$-divisor $\Delta$ on the surface $\widetilde{S}$. Then

$$
\widetilde{\Delta} \sim_{\mathbb{Q}} f^{*}(\Delta)-m E
$$

for some non-negative rational number $m$. To estimate it, observe that

$$
0 \leqslant \widetilde{C}_{x} \cdot \widetilde{\Delta}=\left(f^{*}\left(C_{x}\right)-c E\right) \cdot\left(f^{*}(\Delta)-m E\right)=C_{x} \cdot \Delta-m=C_{x} \cdot\left(D-a C_{x}\right)-m
$$

so that $m \leqslant \frac{1-a}{7}$ for $S_{15}$ and $m \leqslant \frac{1-2 a}{5}$ for $S_{12}$. Now we are ready to prove
Lemma 3.6. The $\log$ pair $\left(S, \frac{6}{5} D\right)$ is $\log$ canonical at $O_{t}$.

Proof. Suppose that the $\log$ pair $\left(S, \frac{6}{5} D\right)$ is not $\log$ canonical at $O_{t}$. Let us seek for a contradiction. Let $\lambda=\frac{6}{5}$. Then

$$
K_{\widetilde{S}}+\lambda a \widetilde{C}_{x}+\lambda \widetilde{\Delta}+\mu E \sim_{\mathbb{Q}} f^{*}\left(K_{S}+\lambda D\right)
$$

where

$$
\begin{array}{ll}
\mu=\frac{15 \lambda a}{7}+\lambda m-\frac{1}{7} & \text { for } S_{15} \\
\mu=\frac{12 \lambda a}{5}+\lambda m-\frac{2}{5} & \text { for } S_{12}
\end{array}
$$

Thus, the log pair

$$
\begin{equation*}
\left(\widetilde{S}, \lambda a \widetilde{C}_{x}+\lambda \widetilde{\Delta}+\mu E\right) \tag{3.7}
\end{equation*}
$$

is not $\log$ canonical at some point $Q \in E$. Note that $\mu \leqslant 1$ because $m \leqslant \frac{1-a}{7}$ (or $m \leqslant \frac{1-2 a}{5}$ ) and $a \leqslant \frac{8}{21}$.

We first apply Lemmas 2.4 or 2.5 to (3.7) and the curve $E$ at the point $Q$. Indeed,

$$
E \cdot \widetilde{\Delta}=E \cdot\left(f^{*}(\Delta)-m E\right)=-m E^{2}=\left\{\begin{array}{l}
\frac{7 m}{15} \leqslant \frac{1-a}{15} \leqslant \frac{1}{6} \quad \text { on } \widetilde{S}_{15}, \\
\frac{5 m}{12} \leqslant \frac{1-2 a}{12} \leqslant \frac{5}{24} \quad \text { on } \widetilde{S}_{12} .
\end{array}\right.
$$

This shows that $Q$ must be the intersection point of $E$ and $\widetilde{C}_{x}$.
Applying Lemma 2.4 again, we see that

$$
\frac{5}{6}=\frac{1}{\lambda}<\left(a \widetilde{C}_{x}+\widetilde{\Delta}\right) \cdot E=a+\widetilde{\Delta} \cdot E= \begin{cases}a+\frac{7 m}{15} \leqslant a+\frac{1-a}{15} & \text { on } \widetilde{S}_{15} \\ a+\frac{5 m}{12} \leqslant a+\frac{1-2 a}{12} & \text { on } \widetilde{S}_{12}\end{cases}
$$

However, these inequalities contradict our assumption $a \leqslant \frac{8}{21}$. Therefore, the $\log$ pair $\left(S, \frac{6}{5} D\right)$ is $\log$ canonical at $O_{t}$.

Proposition 3.2 is completely verified.

## 4. Case B

The way to evaluate $\delta$-invariants for Case B is almost same as that of Case A. In spite of this, we write the proof for the readers' convenience.

In this section, we consider the following two types of quasismooth hypersurfaces:

- $S_{64}$ : a quasismooth hypersurface in $\mathbb{P}(7,15,19,32)$ of degree 64 ;
- $S_{82}$ : a quasismooth hypersurface in $\mathbb{P}(7,19,25,41)$ of degree 82.

As in the previous section, we use $S$ for the surfaces $S_{64}$ and $S_{82}$ if properties or conditions are satisfies by both the surfaces.

We may assume that the surface $S_{64}$ is given by the equation

$$
t^{2}+y^{3} z+x z^{3}+x^{7} y=0
$$

in $\mathbb{P}(7,15,19,32)$ and $S_{82}$ by the equation

$$
t^{2}+y^{3} z+x z^{3}+x^{9} y=0
$$

in $\mathbb{P}(7,19,25,41)$. The surface $S$ is singular at the points $O_{x}=[1: 0: 0: 0], O_{y}=[0: 1: 0: 0]$ and $O_{z}=[0: 0: 1: 0]$, and is smooth away from them. Moreover, the surface $S_{64}$ (resp. $S_{82}$ )
has quotient singularity of types $\frac{1}{7}(5,4), \frac{1}{15}(7,2), \frac{1}{19}(2,3)$ (resp. $\left.\frac{1}{7}(2,3), \frac{1}{19}(7,3), \frac{1}{25}(2,3)\right)$ at the points $O_{x}, O_{y}, O_{z}$, respectively.

Let $C_{x}$ be the curve in $S$ cut out by $x=0$ and $C_{y}$ by $y=0$. Then both the curves $C_{x}$ and $C_{y}$ are irreducible. We have

$$
\begin{aligned}
& \frac{35}{54}=\operatorname{lct}\left(S_{64}, \frac{9}{7} C_{x}\right)<\operatorname{lct}\left(S_{64}, \frac{9}{15} C_{y}\right)=\frac{25}{18} \\
& \frac{7}{12}=\operatorname{lct}\left(S_{82}, \frac{10}{7} C_{x}\right)<\operatorname{lct}\left(S_{82}, \frac{10}{19} C_{y}\right)=\frac{19}{12}
\end{aligned}
$$

which imply $\alpha\left(S_{64}\right) \leqslant \frac{35}{54}$ and $\alpha\left(S_{82}\right) \leqslant \frac{7}{12}$. In fact, we have $\alpha\left(S_{64}\right)=\frac{35}{54}$ and $\alpha\left(S_{82}\right)=\frac{7}{12}$ by [CPS10, Theorem 1.10].
Proposition 4.1. Let $D$ be an effective $\mathbb{Q}$-divisor on $S$ such that

$$
D \sim_{\mathbb{Q}}-K_{S} .
$$

Write $D=a C_{x}+\Delta$, where $a$ is a non-negative number, and $\Delta$ is an effective $\mathbb{Q}$-divisor on the surface $S$ whose support does not contain the curve $C_{x}$. Suppose also that $a \leqslant \frac{1}{2}$. Then the log pair $\left(S, \frac{19}{18} D\right)$ is $\log$ canonical.
Proof. Suppose also that $a \leqslant \frac{1}{2}$.
We first consider a point $P$ that lies neither on $C_{x}$ nor on $C_{y}$. Observe that $P$ is a smooth point of the surface $S$. Since $P \notin C_{x}$, there are complex numbers $c_{1}$ and $c_{2}$ such that $P$ satisfies the following system of equations:

$$
\begin{aligned}
& \left\{\begin{array}{l}
y^{7}+c_{1} x^{15}=0 \\
y^{2} z+c_{2} x^{7}=0
\end{array} \text { for } S_{64} ;\right. \\
& \left\{\begin{array}{l}
y^{4}+c_{1} x^{5} t=0 \\
y^{3}+c_{2} x z^{2}=0
\end{array} \text { for } S_{82} .\right.
\end{aligned}
$$

Moreover, since $P \notin C_{y}$, we have $c_{1} \neq 0$. Let $\mathcal{P}$ be the pencil given by

$$
\begin{aligned}
\nu\left(y^{7}+c_{1} x^{15}\right)+\mu x^{8}\left(y^{2} z+c_{2} x^{7}\right)=0 & \text { on } S_{64} ; \\
\nu\left(y^{4}+c_{1} x^{5} t\right)+\mu y\left(y^{3}+c_{2} x z^{2}\right)=0 & \text { on } S_{82}
\end{aligned}
$$

for $[\nu: \mu] \in \mathbb{P}^{1}$. The base locus of the pencil $\mathcal{P}$ consists of finitely many points. Furthermore, by construction, the point $P$ is one of them. Let $C$ be a general curve in $\mathcal{P}$. Then

$$
\operatorname{mult}_{P}(D) \leqslant C \cdot D \leqslant \frac{18}{19} .
$$

It immediately follows from Corollary 2.2 that the $\log$ pair $\left(S, \frac{19}{18} D\right)$ is $\log$ canonical outside $C_{x}$ and $C_{y}$.

We next consider a point $P$ on $C_{x}$ different from $O_{z}$. Since $a \leqslant \frac{1}{2}$, we apply Lemmas 2.4 and 2.5 to the $\log$ pair $\left(S, \frac{18}{19} a C_{x}+\frac{18}{19} \Delta\right)$. Indeed, since

$$
\begin{gathered}
\left(C_{x} \cdot \Delta\right)_{P} \leqslant C_{x} \cdot \Delta=\frac{18-14 a}{285} \leqslant \frac{6}{95} \quad \text { on } S_{64} \\
\left(C_{x} \cdot \Delta\right)_{P} \leqslant C_{x} \cdot \Delta=\frac{20-14 a}{475} \leqslant \frac{18}{19 \cdot 19} \quad \text { on } S_{82}
\end{gathered}
$$

the $\log$ pair $\left(S, \frac{19}{18} D\right)$ must be $\log$ canonical at $P$.
We now let $P$ be a point on $C_{y}$ different from $O_{z}$. Suppose that the $\log$ pair $\left(S, \frac{19}{18} D\right)$ is not $\log$ canonical at the point $P$. Recall that $\left(S_{64}, \frac{19}{18} \cdot \frac{9}{15} C_{y}\right)$ and $\left(S_{82}, \frac{19}{18} \cdot \frac{10}{19} C_{y}\right)$ are $\log$ canonical,
and the curve $C_{y}$ is irreducible. Thus, it follows from CS08, Remark 2.22] that there exists an effective $\mathbb{Q}$-divisor $D^{\prime}$ on the surface $S$ such that

$$
D^{\prime} \sim_{\mathbb{Q}}-K_{S}
$$

the $\log$ pair $\left(S, \frac{19}{18} D^{\prime}\right)$ is not $\log$ canonical at the point $P$ and the support of the divisor $D^{\prime}$ does not contain the curve $C_{y}$. Observe

$$
C_{y} \cdot D^{\prime}=\left\{\begin{array}{ll}
\frac{18}{19 \cdot 7} & \text { on } S_{64} \\
\frac{4}{35} & \text { on } S_{82}
\end{array}\right\} \leqslant \frac{18}{19 \cdot 7}
$$

This implies that the $\log$ pair $\left(S, \frac{19}{18} D^{\prime}\right)$ is $\log$ canonical at the point $P$. This contradicts our assumption. Thus, we see that $\left(S, \frac{19}{18} D\right)$ is $\log$ canonical away from $O_{z}$. Hence, to complete the proof of Proposition 4.1, we have to show that $\left(S, \frac{19}{18} D\right)$ is $\log$ canonical at the point $O_{z}$.

Recall that $S_{64}$ (resp. $S_{82}$ ) has singularity of type $\frac{1}{19}(2,3)$ (resp. $\frac{1}{25}(2,3)$ ) at the point $O_{z}$. In the chart $z=1$, the surface $S_{64}$ is given by

$$
t^{2}+y^{3}+x+x^{7} y=0
$$

and $S_{82}$ by

$$
t^{2}+y^{3}+x+x^{9} y=0
$$

In a neighborhoods of the point $O_{z}$, we can consider $y$ and $t$ as local weighted coordinates such that $\operatorname{wt}(y)=2$ and $\operatorname{wt}(t)=3$.

Let $f: \widetilde{S} \rightarrow S$ be the weighted blow up at the singular point $O_{z}$ with weights $\operatorname{wt}(y)=2$ and $\operatorname{wt}(t)=3$. Denote by $E$ the exceptional curve of the blow up $f$. Then

$$
\begin{aligned}
& K_{\widetilde{S}_{64}} \sim_{\mathbb{Q}} f^{*}\left(K_{S_{64}}\right)-\frac{14}{19} E ; \\
& K_{\widetilde{S}_{82}} \sim_{\mathbb{Q}} f^{*}\left(K_{S_{82}}\right)-\frac{20}{25} E .
\end{aligned}
$$

The surface $S$ has two singular points in $E$. One is a point of type $\frac{1}{2}(1,1)$ and the other is of type $\frac{1}{3}(1,1)$. Denote the former by $O_{2}$ and the latter by $O_{3}$. Observe

$$
\begin{array}{ll}
E^{2}=-\frac{19}{6} & \text { on } \widetilde{S}_{64} \\
E^{2}=-\frac{25}{6} & \text { on } \widetilde{S}_{82}
\end{array}
$$

and $E \cong \mathbb{P}^{1}$.
Let $\widetilde{C}_{x}$ be the proper transform of the curve $C_{x}$ on the surface $\widetilde{S}$. Then

$$
\widetilde{C}_{x} \sim_{\mathbb{Q}} f^{*}\left(C_{x}\right)-c E,
$$

where $c=\frac{6}{19}$ for $S_{64}$ and $c=\frac{6}{25}$ for $S_{82}$, and the intersection $E \cap \widetilde{C}_{x}$ consists of a single point different from $O_{2}$ and $O_{3}$. Note that the curves $E$ and $\widetilde{C}_{x}$ intersect transversally.

Denote by $\widetilde{\Delta}$ be the proper transform of the $\mathbb{Q}$-divisor $\Delta$ on the surface $\widetilde{S}$. Then

$$
\widetilde{\Delta} \sim_{\mathbb{Q}} f^{*}(\Delta)-m E
$$

for some non-negative rational number $m$. To estimate it, observe

$$
0 \leqslant \widetilde{C}_{x} \cdot \widetilde{\Delta}=\left(f^{*}\left(C_{x}\right)-c E\right) \cdot\left(f^{*}(\Delta)-m E\right)=C_{x} \cdot \Delta-m=C_{x} \cdot\left(D-a C_{x}\right)-m
$$

This implies $m \leqslant \frac{18-14 a}{285}$ for $S_{64}$ and $m \leqslant \frac{20-14 a}{19.25}$ for $S_{82}$.

We finally suppose that the $\log$ pair $\left(S, \frac{19}{18} D\right)$ is not $\log$ canonical at $O_{z}$. Let $\lambda=\frac{19}{18}$. Then

$$
K_{\widetilde{S}}+\lambda a \widetilde{C}_{x}+\lambda \widetilde{\Delta}+\mu E \sim_{\mathbb{Q}} f^{*}\left(K_{S}+\lambda D\right)
$$

where

$$
\begin{array}{ll}
\mu=\frac{6 \lambda a}{19}+\lambda m+\frac{14}{19} & \text { for } S_{64} \\
\mu=\frac{6 \lambda a}{25}+\lambda m+\frac{20}{25} & \text { for } S_{82}
\end{array}
$$

Thus, the log pair

$$
\begin{equation*}
\left(\widetilde{S}, \lambda a \widetilde{C}_{x}+\lambda \widetilde{\Delta}+\mu E\right) \tag{4.2}
\end{equation*}
$$

is not $\log$ canonical at some point $Q \in E$.
Using $m \leqslant \frac{18-14 a}{15 \cdot 19}$ for $S_{64}, m \leqslant \frac{20-14 a}{19 \cdot 25}$ for $S_{82}$ and $a \leqslant \frac{1}{2}$, we get

$$
\begin{gathered}
\frac{6 \lambda a}{19}+\lambda m+\frac{14}{19} \leqslant \frac{4 \lambda a}{15}+\frac{6 \lambda}{95}+\frac{14}{19} \leqslant \frac{56 \lambda}{285}+\frac{14}{19}=\frac{2422}{2565}<1, \\
\frac{6 \lambda a}{25}+\lambda m+\frac{20}{25} \leqslant \frac{4 \lambda a}{19}+\frac{4 \lambda}{95}+\frac{4}{5} \leqslant \frac{14 \lambda}{95}+\frac{4}{5}=\frac{817}{855}<1 .
\end{gathered}
$$

Since

$$
E \cdot \widetilde{\Delta}=E \cdot\left(f^{*}(\Delta)-m E\right)=-m E^{2}=\left\{\begin{array}{l}
\frac{19 m}{6} \leqslant \frac{9-7 a}{45} \leqslant \frac{6}{19} \quad \text { on } \widetilde{S}_{64}, \\
\frac{25 m}{6} \leqslant \frac{20-14 a}{6 \cdot 19} \leqslant \frac{6}{19} \quad \text { on } \widetilde{S}_{82} .
\end{array}\right.
$$

Lemmas 2.4 and 2.5 imply that $Q$ must be the intersection point of $E$ and $\widetilde{C}_{x}$. It then follows from Lemma 2.4 that

$$
\frac{18}{19}=\frac{1}{\lambda}<\left(a \widetilde{C}_{x}+\widetilde{\Delta}\right) \cdot E=a+\widetilde{\Delta} \cdot E=\left\{\begin{array}{l}
a+\frac{19 m}{6} \leqslant a+\frac{9-7 a}{45} \quad \text { on } \widetilde{S}_{64} \\
a+\frac{25 m}{6} \leqslant a+\frac{20-14 a}{6 \cdot 19} \quad \text { on } \widetilde{S}_{82}
\end{array}\right.
$$

This contradicts our assumption $a \leqslant \frac{1}{2}$. The obtained contradiction completes the proof.
Corollary 4.3. One has $\delta(S) \geqslant \frac{19}{18}$.
Proof. See the proof of Corollary 3.3.

## 5. Case C

In this section, we consider the following three types of quasismooth hypersurfaces:

- $S_{45}$ : a quasismooth hypersurface in $\mathbb{P}(7,10,15,19)$ of degree 45 ;
- $S_{81}$ : a quasismooth hypersurface in $\mathbb{P}(7,18,27,37)$ of degree 81 ;
- $S_{117}$ : a quasismooth hypersurface in $\mathbb{P}(7,26,39,55)$ of degree 117.

As in the previous sections, we use $S$ for all the surfaces $S_{45}, S_{81}$, and $S_{117}$ if properties or conditions are satisfies by all the surfaces.

By appropriate coordinate changes, we may assume that the surface $S_{45}$ is defined by the equation

$$
z^{3}-y^{3} z+x t^{2}+x^{5} y=0
$$

in $\mathbb{P}(7,10,15,19)$, the surface $S_{81}$ by

$$
\begin{gathered}
z^{3}-y^{3} z+x t^{2}+x^{9} y=0 \\
16
\end{gathered}
$$

in $\mathbb{P}(7,18,27,37)$, and the surface $S_{117}$ by

$$
z^{3}-y^{3} z+x t^{2}+x^{13} y=0
$$

in $\mathbb{P}(7,26,39,55)$.
The surface $S$ is singular at the points

$$
O_{x}=[1: 0: 0: 0], O_{y}=[0: 1: 0: 0], O_{t}=[0: 0: 0: 1], Q=[0: 1: 1: 0],
$$

and is smooth away from them. Moreover, the surface $S_{45}$ (resp. $S_{81}$ and $S_{117}$ ) has quotient singularity of types $\frac{1}{7}(1,5), \frac{1}{10}(7,9), \frac{1}{19}(2,3), \frac{1}{5}(1,2)$ (resp. $\frac{1}{7}(3,1), \frac{1}{18}(7,1), \frac{1}{37}(2,3), \frac{1}{9}(7,1)$ and $\left.\frac{1}{7}(2,3), \frac{1}{26}(7,3), \frac{1}{55}(2,3), \frac{1}{13}(7,3)\right)$ at the points $O_{x}, O_{y}, O_{t}, Q$, respectively.

Let $C_{x}$ be the curve in $S$ that is cut out by $x=0$. Then

$$
C_{x}=L_{x z}+R_{x}
$$

where $L_{x z}$ is the curve given by $x=z=0$ and $R_{x}$ by $x=z^{2}-y^{3}=0$ in the ambient weighted projective space. These two curves $L_{x z}$ and $R_{x}$ meets each other at the point $O_{t}$. Also, we have

$$
\begin{array}{llll}
L_{x z}^{2}=-\frac{23}{10 \cdot 19}, & R_{x}^{2}=-\frac{8}{5 \cdot 19}, \quad L_{x z} \cdot R_{x}=\frac{3}{19} & \text { on } S_{45} ; \\
L_{x z}^{2}=-\frac{47}{18 \cdot 37}, & R_{x}^{2}=-\frac{20}{9 \cdot 37}, & L_{x z} \cdot R_{x}=\frac{3}{37} & \text { on } S_{81} ;  \tag{5.1}\\
L_{x z}^{2}=-\frac{71}{26 \cdot 55}, & R_{x}^{2}=-\frac{32}{13 \cdot 55}, \quad L_{x z} \cdot R_{x}=\frac{3}{55} & \text { on } S_{117} .
\end{array}
$$

Note also that the curve $R_{x}$ is singular at the point $O_{t}$.
Let $C_{y}$ be the curve in $S$ cut out by $y=0$. Then $C_{y}$ is irreducible and

$$
\begin{aligned}
& \frac{35}{54}=\operatorname{lct}\left(S_{45}, \frac{6}{7} C_{x}\right)<\operatorname{lct}\left(S_{45}, \frac{6}{10} C_{y}\right)=\frac{25}{18} \\
& \frac{35}{72}=\operatorname{lct}\left(S_{81}, \frac{8}{7} C_{x}\right)<\operatorname{lct}\left(S_{81}, \frac{8}{18} C_{y}\right)=\frac{15}{8} \\
& \frac{7}{18}=\operatorname{lct}\left(S_{117}, \frac{10}{7} C_{x}\right)<\operatorname{lct}\left(S_{117}, \frac{10}{26} C_{y}\right)=\frac{13}{6}
\end{aligned}
$$

In fact, in these three cases $\alpha(S)$ is given by the numbers $\frac{35}{54}, \frac{35}{72}$, and $\frac{7}{18}$ on the left-hand sides by [CPS10, Theorem 1.10].

To estimate $\delta(S)$, we fix an effective $\mathbb{Q}$-divisor $D$ on the surface $S$ such that

$$
D \sim_{\mathbb{Q}}-K_{S}
$$

and write $D=a L_{x z}+b R_{x}+\Delta$, where $a$ and $b$ are non-negative numbers, and $\Delta$ is an effective $\mathbb{Q}$-divisor on the surface $S$ whose support does not contain the curves $L_{x z}$ and $R_{x}$.

Lemma 5.2. If the $\mathbb{Q}$-divisor $D$ is of $k$-basis type with $k \gg 0$, then

$$
a \leqslant\left\{\begin{array}{l}
\frac{2}{5} \\
\frac{1}{2} \\
\frac{11}{20}
\end{array}\right\}, \quad b \leqslant\left\{\begin{array}{ll}
\frac{1}{3} & \text { on } S_{45} \\
\frac{1}{5} & \text { on } S_{81} \\
\frac{12}{25} & \text { on } S_{117}
\end{array}\right\} .
$$

Proof. Suppose that $D$ is of $k$-basis type with $k \gg 0$. Theorem 2.9 implies that

$$
a \leqslant \frac{1}{\left(-K_{S}\right)^{2}} \int_{0}^{\infty} \operatorname{vol}\left(-K_{S}-\lambda L_{x z}\right) d \lambda+\epsilon_{k}
$$

where $\epsilon_{k}$ is a small constant depending on $k$ such that $\epsilon_{k} \rightarrow 0$ as $k \rightarrow \infty$. Since

$$
-K_{S}-\lambda L_{x z} \sim_{\mathbb{Q}} \begin{cases}\left(\frac{6}{7}-\lambda\right) L_{x z}+\frac{6}{7} R_{x} & \text { on } S_{45} \\ \left(\frac{8}{7}-\lambda\right) L_{x z}+\frac{8}{7} R_{x} & \text { on } S_{81} \\ \left(\frac{10}{7}-\lambda\right) L_{x z}+\frac{10}{7} R_{x} & \text { on } S_{117}\end{cases}
$$

and $R_{x}^{2}<0$, we have $\operatorname{vol}\left(-K_{S}-\lambda L_{x z}\right)=0$ for $\lambda \geqslant \frac{6}{7}$ on $S_{45}, \lambda \geqslant \frac{8}{7}$ on $S_{81}$ and $\lambda \geqslant \frac{10}{7}$ on $S_{117}$. Similarly, using (5.1), we see that

$$
\left(-K_{S}-\lambda L_{x z}\right) \cdot R_{x}=\left\{\begin{array}{l}
\left(\left(\frac{6}{7}-\lambda\right) L_{x z}+\frac{6}{7} R_{x}\right) \cdot R_{x}=\frac{6-15 \lambda}{19 \cdot 5} \quad \text { on } S_{45} \\
\left(\left(\frac{8}{7}-\lambda\right) L_{x z}+\frac{8}{7} R_{x}\right) \cdot R_{x}=\frac{8-27 \lambda}{37 \cdot 9} \quad \text { on } S_{81} \\
\left(\left(\frac{10}{7}-\lambda\right) L_{x z}+\frac{10}{7} R_{x}\right) \cdot R_{x}=\frac{10-39 \lambda}{13 \cdot 55} \quad \text { on } S_{117} .
\end{array}\right.
$$

This shows that the divisor $-K_{S}-\lambda L_{x z}$ is nef for $\lambda \leqslant \frac{2}{5}$ on $S_{45}, \lambda \leqslant \frac{8}{27}$ on $S_{81}$ and $\lambda \leqslant \frac{10}{39}$ on $S_{117}$. Thus, we have

$$
\operatorname{vol}\left(-K_{S}-\lambda L_{x z}\right)=\left(-K_{S}-\lambda L_{x z}\right)^{2}= \begin{cases}\frac{54}{665}-\frac{6 \lambda}{95}-\frac{23 \lambda^{2}}{190} & \text { for } \lambda \leqslant \frac{2}{5} \text { on } S_{45} \\ \frac{32}{777}-\frac{8 \lambda}{333}-\frac{47 \lambda^{2}}{666} & \text { for } \lambda \leqslant \frac{8}{27} \text { on } S_{81} \\ \frac{200}{7007}-\frac{12 \lambda}{1001}-\frac{36}{715} \lambda^{2} \quad \text { for } \lambda \leqslant \frac{10}{39} \text { on } S_{117} .\end{cases}
$$

To compute $\operatorname{vol}\left(-K_{S}-\lambda L_{x z}\right)$ for $\frac{2}{5}<\lambda<\frac{6}{7}$ on $S_{45}, \frac{8}{27}<\lambda<\frac{8}{7}$ on $S_{81}$ and $\frac{10}{39}<\lambda<\frac{10}{7}$ on $S_{117}$, we let

$$
N= \begin{cases}\left(\frac{6}{7}-\lambda\right) L_{x z}+\left(\frac{6}{7}-\frac{15 \lambda-6}{8}\right) R_{x} & \text { for } S_{45} \\ \left(\frac{8}{7}-\lambda\right) L_{x z}+\left(\frac{8}{7}-\frac{27 \lambda-8}{20}\right) R_{x} \quad \text { for } S_{81} \\ \left(\frac{10}{7}-\lambda\right) L_{x z}+\left(\frac{10}{7}-\frac{39 \lambda-10}{32}\right) R_{x} \quad \text { for } S_{117}\end{cases}
$$

Then, using (5.1) again, we see that $N \cdot R_{x}=0$ and $N \cdot L_{x z} \geqslant 0$. Thus, we conclude that the divisor $N$ is nef on the respective interval for $\lambda$. This shows that

$$
-K_{S}-\lambda L_{x z} \sim_{\mathbb{Q}}\left\{\begin{array}{cl}
N+\frac{15 \lambda-6}{8} R_{x} & \text { on } S_{45} \\
N+\frac{27 \lambda-8}{20} R_{x} & \text { on } S_{81} \\
N+\frac{39 \lambda-10}{32} R_{x} & \text { on } S_{117} \\
18
\end{array}\right.
$$

is the Zariski decomposition of the divisor $-K_{S}-\lambda L_{x z}$. Hence, we have

$$
\operatorname{vol}\left(-K_{S}-\lambda L_{x z}\right)=N^{2}= \begin{cases}\frac{1}{280}(6-7 \lambda)^{2} & \text { on } S_{45} \\ \frac{1}{1260}(8-7 \lambda)^{2} & \text { on } S_{81} \\ \frac{369}{1121120}(10-7 \lambda)^{2} & \text { on } S_{117}\end{cases}
$$

by (2.8). Thus, integrating, we get

$$
a \leqslant \frac{1}{\left(-K_{S}\right)^{2}} \int_{0}^{\infty} \operatorname{vol}\left(-K_{S}-\lambda L_{x z}\right) d \lambda+\epsilon_{k}= \begin{cases}\frac{118}{315}+\epsilon_{k} & \text { for } S_{45} \\ \frac{760}{1701}+\epsilon_{k} & \text { for } S_{81} \\ \frac{8780}{17199}+\epsilon_{k} & \text { for } S_{117}\end{cases}
$$

This gives us the asserted bounds for $a$.
Meanwhile, we have

$$
\operatorname{vol}\left(-K_{S}-\lambda R_{x}\right)=\left(-K_{S}-\lambda R_{x}\right)^{2}=\left\{\begin{array}{l}
\frac{54}{665}-\frac{12 \lambda}{95}-\frac{8 \lambda^{2}}{95} \quad \text { for } 0 \leqslant \lambda \leqslant \frac{1}{5} \text { on } S_{45} \\
\frac{32 \cdot 21}{9 \cdot 37 \cdot 49}-\frac{16 \lambda}{9 \cdot 37}-\frac{20 \lambda^{2}}{9 \cdot 37} \quad \text { for } 0 \leqslant \lambda \leqslant \frac{4}{27} \text { on } S_{81} \\
\frac{30}{1001}-\frac{4 \lambda}{143}-\frac{32 \lambda^{2}}{715} \quad \text { for } 0 \leqslant \lambda \leqslant \frac{5}{39} \text { on } S_{117} .
\end{array}\right.
$$

since the divisor $-K_{S}-\lambda R_{x}$ is nef for the values $\lambda$ in the respective interval. The Zariski decomposition of the divisor $-K_{S}-\lambda R_{x}$ is given by

$$
\begin{cases}\underbrace{\left(\frac{6}{7}-\frac{30 \lambda-6}{23}\right) L_{x z}+\left(\frac{6}{7}-\lambda\right) R_{x}}_{\text {nef } \mathbb{R} \text {-divisor }}+\frac{30 \lambda-6}{23} L_{x z} & \text { for } \frac{1}{5}<\lambda \leqslant \frac{6}{7} \text { on } S_{45} \\ \underbrace{\left(\frac{8}{7}-\frac{54 \lambda-8}{47}\right) L_{x z}+\left(\frac{8}{7}-\lambda\right) R_{x}}_{\text {nef } \mathbb{R} \text {-divisor }}+\frac{54 \lambda-8}{47} L_{x z} & \text { for } \frac{4}{27}<\lambda \leqslant \frac{8}{7} \text { on } S_{81} \\ \underbrace{\left(\frac{10}{7}-\frac{78 \lambda-10}{71}\right) L_{x z}+\left(\frac{10}{7}-\lambda\right) R_{x}}_{\text {nef } \mathbb{R} \text {-divisor }}+\frac{78 \lambda-10}{71} L_{x z} & \text { for } \frac{5}{39}<\lambda \leqslant \frac{10}{7} \text { on } S_{117}\end{cases}
$$

so that we could obtain

$$
\operatorname{vol}\left(-K_{S}-\lambda R_{x}\right)=\left\{\begin{array}{l}
\left(\left(\frac{6}{7}-\frac{30 \lambda-6}{23}\right) L_{x z}+\left(\frac{6}{7}-\lambda\right) R_{x}\right)^{2}=\frac{2}{5 \cdot 7 \cdot 23}(6-7 \lambda)^{2} \\
\left(\left(\frac{8}{7}-\frac{54 \lambda-8}{47}\right) L_{x z}+\left(\frac{8}{7}-\lambda\right) R_{x}\right)^{2}=\frac{2}{7 \cdot 9 \cdot 47}(8-7 \lambda)^{2} \\
\left(\left(\frac{10}{7}-\frac{78 \lambda-10}{71}\right) L_{x z}+\left(\frac{10}{7}-\lambda\right) R_{x}\right)^{2}=\frac{2}{7 \cdot 13 \cdot 71}(10-7 \lambda)^{2} .
\end{array}\right.
$$

Finally, $\operatorname{vol}\left(-K_{S}-\lambda R_{x}\right)=0$ for $\lambda>\frac{6}{7}$ on $S_{45}$, for $\lambda>\frac{8}{7}$ on $S_{81}$, and for $\lambda>\frac{10}{7}$ on $S_{117}$ since $-K_{S}-\lambda R_{x}$ is not pseudoeffective for these values $\lambda$. Thus, by Theorem [2.9, we have

$$
b \leqslant \frac{1}{\left(-K_{S}\right)^{2}} \int_{0}^{\infty} \operatorname{vol}\left(-K_{S}-\lambda R_{x}\right) d \lambda+\varepsilon_{k}=\left\{\begin{array}{l}
\frac{97}{315}+\varepsilon_{k} \\
\text { for } S_{45} \\
\frac{10709068}{58281363}+\varepsilon_{k} \quad \text { for } S_{81} \\
\frac{1205}{2457}+\varepsilon_{k}
\end{array} \text { for } S_{117} .\right.
$$

This yields the required bounds for $b$.
Now we prove the main assertion in this section.
Proposition 5.3. If $a$ and $b$ satisfies the bounds in Lemma 5.2 then the $\log$ pair $(S, 650)$ is $\log$ canonical.

Proof. We suppose that $a$ and $b$ satisfies the bounds in Lemma 5.2 .
We fist claim that the $\log$ pair $\left(S, \frac{65}{64} D\right)$ is $\log$ canonical outside of $C_{x}$ and $C_{y}$. This immediately follows from the same argument as in the beginning of the proof of Proposition 4.1 with the pencil $\mathcal{P}$ given by

$$
\begin{array}{ll}
\nu\left(x^{10}+c_{1} y^{7}\right)+\mu y^{4}\left(z^{2}+c_{2} y^{3}\right)=0 & \text { on } S_{45} \\
\nu\left(x^{18}+c_{1} y^{7}\right)+\mu y^{4}\left(z^{2}+c_{2} y^{3}\right)=0 & \text { on } S_{81} \\
\nu\left(x^{26}+c_{1} y^{7}\right)+\mu y^{4}\left(z^{2}+c_{2} y^{3}\right)=0 & \text { on } S_{117}
\end{array}
$$

where $c_{1}$ and $c_{2}$ are appropriate constants, for $[\nu: \mu] \in \mathbb{P}^{1}$. For a general member $C$ in $\mathcal{P}$ we obtain

$$
C \cdot D \leqslant \frac{64}{65}
$$

which verifies the claim. Notice that the surface $S$ is smooth outside $C_{x}$ and $C_{y}$.
We now consider a point $P$ on $C_{y}$ different from $O_{t}$. Suppose that the $\log$ pair $\left(S, \frac{65}{64} D\right)$ is not $\log$ canonical at the point $P$. Recall that $\left(S, \frac{65 e}{64} C_{y}\right)$ is $\log$ canonical, where $e$ is the positive rational number such that $-K_{S} \sim_{\mathbb{Q}} e C_{y}$, and that the curve $C_{y}$ is irreducible. Thus, it follows from CS08, Remark 2.22] that there exists an effective $\mathbb{Q}$-divisor $D^{\prime}$ on the surface $S$ such that

$$
D^{\prime} \sim_{\mathbb{Q}}-K_{S},
$$

the $\log$ pair $\left(S, \frac{65}{64} D^{\prime}\right)$ is not $\log$ canonical at the point $P$, and the support of the divisor $D^{\prime}$ does not contain the curve $C_{y}$. Observe that

$$
C_{y} \cdot D^{\prime} \leqslant \frac{64}{7 \cdot 65} .
$$

This implies that the $\log$ pair $\left(S, \frac{65}{64} D^{\prime}\right)$ is $\log$ canonical at the point $P$. This contradiction shows that the $\log$ pair $\left(S, \frac{65}{64} D\right)$ is $\log$ canonical outside $C_{x}$.

Let $P$ be a point on $C_{x}$ other than $O_{t}$. We have two cases for the location of $P$, i.e., when $P$ lies on $L_{x z}$ and when it lies on $R_{x}$. Note that we always have $\frac{65 a}{64}<1$ and $\frac{65 b}{64}<1$.

We first consider the case where $P$ belongs to $L_{x z}$. Then the log pair ( $S, L_{x z}+\frac{65 b}{64} R_{x}+\frac{65}{64} \Delta$ ) is $\log$ canonical at $P$. Indeed,

$$
\left(b R_{x}+\Delta\right) \cdot L_{x z}=\left(D-a L_{x z}\right) \cdot L_{x z}= \begin{cases}\frac{6+23 a}{190} \leqslant \frac{64}{65 \cdot 10} & \text { for } S_{45} \\ \frac{8+47 a}{37 \cdot 18} \leqslant \frac{64}{65 \cdot 18} & \text { for } S_{81} \\ \frac{10+71 a}{55 \cdot 26} \leqslant \frac{64}{65 \cdot 26} & \text { for } S_{117}\end{cases}
$$

Lemmas 2.4 or 2.5 imply that $\left(S, \frac{65}{64} D\right)$ is $\log$ canonical at the point $P$. If the point $P$ must lie on $R_{x}$, then we consider

$$
\left(a L_{x z}+\Delta\right) \cdot R_{x}=\left(D-b R_{x}\right) \cdot R_{x}= \begin{cases}\frac{3+8 b}{95} \leqslant \frac{64}{65 \cdot 5} & \text { for } S_{45} \\ \frac{8+20 b}{9 \cdot 37} \leqslant \frac{64}{65 \cdot 9} & \text { for } S_{81} \\ \frac{10+32 b}{13 \cdot 55} \leqslant \frac{64}{65 \cdot 13} & \text { for } S_{117}\end{cases}
$$

Lemmas 2.4 or 2.5 then show that $\left(S, \frac{65}{64} D\right)$ is $\log$ canonical at the point $P$.
Now it is enough to show that $\left(S, \frac{65}{64} \mathrm{D}\right)$ is $\log$ canonical at $O_{t}$.
Recall that $S_{45}$ (resp. $S_{81}$ snd $S_{117}$ ) has singularity of type $\frac{1}{19}(2,3)$ (resp. $\frac{1}{37}(2,3)$ and $\frac{1}{55}(2,3)$ ) at the point $O_{t}$. In the chart given by $t=1$, the surface $S_{45}$ is given by

$$
z^{3}-y^{3} z+x+x^{5} y=0
$$

the surface $S_{81}$ by

$$
z^{3}-y^{3} z+x+x^{9} y=0
$$

and the surface $S_{117}$ by

$$
z^{3}-y^{3} z+x+x^{13} y=0
$$

In a neighborhood of the point $O_{t}$, we can consider $y$ and $z$ as local weighted coordinates such that $\mathrm{wt}(y)=2$ and $\mathrm{wt}(z)=3$.

Let $f: \widetilde{S} \rightarrow S$ be the weighted blow up at the singular point $O_{t}$ such that $\operatorname{wt}(y)=2$ and $\operatorname{wt}(z)=3$. Denote by $E$ the exceptional curve of the blow up $f$. Then

$$
\begin{aligned}
K_{\widetilde{S}_{45}} \sim_{\mathbb{Q}} f^{*}\left(K_{S_{45}}\right)-\frac{14}{19} E \\
K_{\widetilde{S}_{81}} \sim_{\mathbb{Q}} f^{*}\left(K_{S_{81}}\right)-\frac{32}{37} E \\
K_{\widetilde{S}_{117}} \sim_{\mathbb{Q}} f^{*}\left(K_{S_{117}}\right)-\frac{10}{11} E .
\end{aligned}
$$

The surface $S$ has two singular points in $E$. One is of type $\frac{1}{2}(1,1)$ and the other is of type $\frac{1}{3}(1,1)$. Denote the former one by $O_{2}$ and the latter one by $O_{3}$. Observe

$$
E^{2}= \begin{cases}-\frac{19}{6} & \text { on } \widetilde{S}_{45} \\ -\frac{37}{6} & \text { on } \widetilde{S}_{81} \\ -\frac{55}{6} & \text { on } \widetilde{S}_{117}\end{cases}
$$

and $E \cong \mathbb{P}^{1}$.

Let $\widetilde{L}_{x z}$ and $\widetilde{R}_{x}$ be the proper transforms of the curve $L_{x z}$ and $R_{x}$ to the surface $\widetilde{S}$, respectively. Then

$$
\widetilde{L}_{x z} \sim_{\mathbb{Q}} f^{*}\left(L_{x z}\right)-\frac{3}{c} E, \quad \widetilde{R}_{x} \sim_{\mathbb{Q}} f^{*}\left(R_{x}\right)-\frac{6}{c} E
$$

where $c$ is the index of singularity $O_{t}$. The intersection $E \cap \widetilde{L}_{x z}$ consists of the point $O_{2}$ and the intersection $E \cap \widetilde{R}_{x}$ consists of a single smooth point. Note that $\widetilde{L}_{x z} \cdot E=\frac{1}{2}$ and the curves $E$ and $\widetilde{R}_{x}$ intersect transversally.

Recall that $\underset{\widetilde{S}}{D}=a L_{x z}+b R_{x}+\Delta$. Denote by $\widetilde{\Delta}$ be the proper transform of the $\mathbb{Q}$-divisor $\Delta$ on the surface $\widetilde{S}$. Then

$$
\widetilde{\Delta} \sim_{\mathbb{Q}} f^{*}(\Delta)-m E
$$

for some non-negative rational number $m$. To estimate $m$, consider the intersection

$$
0 \leqslant \widetilde{R}_{x} \cdot \widetilde{\Delta}=\widetilde{R}_{x} \cdot\left(f^{*}(\Delta)-m E\right)=R_{x} \cdot \Delta-m
$$

Applying (5.1), we are able to obtain

$$
m \leqslant\left\{\begin{array}{l}
\frac{6}{5 \cdot 19}-\frac{3 a}{19}+\frac{8 b}{5 \cdot 19} \leqslant \frac{6}{5 \cdot 19}+\frac{8 b}{5 \cdot 19} \leqslant \frac{26}{285} \quad \text { for } S_{45}  \tag{5.4}\\
\frac{8}{9 \cdot 37}-\frac{3 a}{37}+\frac{20 b}{9 \cdot 37} \leqslant \frac{8}{9 \cdot 37}+\frac{20 b}{9 \cdot 37} \leqslant \frac{4}{111} \quad \text { for } S_{81} \\
\frac{2}{11 \cdot 13}-\frac{3 a}{55}+\frac{32 b}{13 \cdot 55} \leqslant \frac{2}{11 \cdot 13}+\frac{32 b}{13 \cdot 55} \leqslant \frac{634}{17875} \quad \text { for } S_{117}
\end{array}\right.
$$

We now suppose that the $\log$ pair $\left(S, \frac{65}{64} D\right)$ is not $\log$ canonical at $O_{t}$. Put $\lambda=\frac{65}{64}$. Then

$$
K_{\widetilde{S}}+\lambda a \widetilde{L}_{x z}+\lambda b \widetilde{R}_{x}+\lambda \widetilde{\Delta}+\mu E \sim_{\mathbb{Q}} f^{*}\left(K_{S}+\lambda D\right)
$$

where

$$
\mu= \begin{cases}\frac{3 \lambda a}{19}+\frac{6 \lambda b}{19}+\lambda m+\frac{14}{19} & \text { for } S_{45} \\ \frac{3 \lambda a}{37}+\frac{6 \lambda b}{37}+\lambda m+\frac{32}{37} & \text { for } S_{81} \\ \frac{3 \lambda a}{55}+\frac{6 \lambda b}{55}+\lambda m+\frac{10}{11} & \text { for } S_{117}\end{cases}
$$

Thus, the log pair

$$
\begin{equation*}
\left(\widetilde{S}, \lambda a \widetilde{L}_{x z}+\lambda b \widetilde{R}_{x}+\lambda \widetilde{\Delta}+\mu E\right) \tag{5.5}
\end{equation*}
$$

is not $\log$ canonical at some point $O \in E$. Using (5.4) and bounds for $b$, we can easily check

$$
\mu \leqslant \begin{cases}\frac{3 \lambda a}{19}+\frac{6 \lambda b}{19}+\frac{6 \lambda}{95}-\frac{3 a \lambda}{19}+\frac{8 \lambda b}{95}+\frac{14}{19}=\frac{2 \lambda b}{5}+\frac{6 \lambda}{95}+\frac{14}{19} \leqslant 1 \quad \text { for } S_{45}, & \\ \frac{3 \lambda a}{37}+\frac{6 \lambda b}{37}+\frac{8 \lambda}{9 \cdot 37}-\frac{3 \lambda a}{37}+\frac{20 \lambda b}{9 \cdot 37}+\frac{32}{37}=\frac{2 \cdot 29 \lambda b}{3 \cdot 37}+\frac{8 \lambda}{9 \cdot 37}+\frac{32}{37} \leqslant 1 & \text { for } S_{81}, \\ \frac{3 \lambda a}{55}+\frac{6 \lambda b}{55}+\frac{2 \lambda}{11 \cdot 13}-\frac{3 \lambda a}{55}+\frac{32 \lambda b}{13 \cdot 55}+\frac{10}{11}=\frac{2 \lambda b}{13}+\frac{2 \lambda}{11 \cdot 13}+\frac{10}{11} \leqslant 1 & \text { for } S_{117} .\end{cases}
$$

If $O=E \cap \widetilde{R}_{x}$, then we apply Lemma 2.4 to (5.5) and $E$. This yields

$$
\lambda b+\lambda \widetilde{\Delta} \cdot E=\underset{22}{\left.\lambda b \widetilde{R}_{x}+\lambda \widetilde{\Delta}\right) \cdot E>1,}
$$

so that we could obtain absurd inequalities

$$
\frac{64}{65}=\frac{1}{\lambda}<b+\widetilde{\Delta} \cdot E=b+\frac{c m}{6} \leqslant\left\{\begin{array}{l}
\frac{1}{3}+\frac{19}{60}=\frac{13}{20} \quad \text { for } S_{45} \\
\frac{1}{5}+\frac{37}{6 \cdot 25}=\frac{67}{150} \quad \text { for } S_{81}, \\
\frac{12}{25}+\frac{1}{3}=\frac{61}{75} \quad \text { for } S_{117}
\end{array}\right.
$$

where $c$ is the index of the singularity $O_{t}$. The inequality

$$
\widetilde{\Delta} \cdot E=\frac{c m}{6} \leqslant\left\{\begin{array}{lc}
\frac{13}{45} & \text { for } S_{45}, \\
\frac{2}{9} & \text { for } S_{81}, \\
\frac{317}{975} & \text { for } S_{117} .
\end{array}\right\} \leqslant \frac{1}{3 \lambda}=\frac{64}{3 \cdot 65}
$$

implies that $O=O_{2}$. However, using (5.4) and Lemma 2.5 (applied to (5.5) and $E$ ), we conclude that the $\log$ pair (5.5) is $\log$ canonical everywhere since

$$
\left(a \widetilde{L}_{x z}+\widetilde{\Delta}\right) \cdot E=\frac{a}{2}+\widetilde{\Delta} \cdot E=\frac{a}{2}+\frac{c m}{6} \leqslant\left\{\begin{array}{l}
\frac{1}{5}+\frac{4 b}{15} \leqslant \frac{13}{45} \quad \text { for } S_{45}, \\
\frac{4}{27}+\frac{10 b}{27} \leqslant \frac{2}{9} \quad \text { for } S_{81}, \\
\frac{5}{39}+\frac{16 b}{39} \leqslant \frac{317}{975} \\
\text { for } S_{117},
\end{array}\right\} \leqslant \frac{1}{2 \lambda}=\frac{32}{65}
$$

This completes the proof.
Corollary 5.6. The $\delta$-invariant of $S$ is at least $\frac{65}{64}$.
Proof. This immediately follows from Proposition 5.3 and Lemma 5.2
