Preface

I gave a course at the University of Bonn during the winter term 1987/88 under the title "Manifolds and Modular Forms". The theory of "Elliptic Genera" is relatively new at the time. The word "genus" is meant in the sense of my book "Neue Topologische Methoden in der Algebraischen Geometrie" published in 1956. A genus is a homomorphism of the Thom cobordism ring of oriented compact manifolds into the complex numbers. Fundamental examples are the signature and the $\hat{A}$-genus. The $\hat{A}$-genus equals the arithmetic genus of an algebraic manifold, provided the first Chern class of the manifold vanishes. According to Atiyah and Singer it is the index of the Dirac operator on a compact Riemannian manifold with spin structure.

Elliptic genera depend on a parameter. For special values of the parameter one obtains the signature and the $\hat{A}$-genus. Indeed, the universal elliptic genus can be regarded as a modular form with respect to the subgroup $\Gamma_0(2)$ of the modular group; the two cusps giving the signature and the $\hat{A}$-genus.

Witten and other physicists have given motivations for the elliptic genus by theoretical physics using the free loop space of a manifold. This led Witten to conjectures concerning the rigidity of the elliptic genus generalizing a result of Atiyah and myself on the rigidity of the equivariant $\hat{A}$-genus:

If the circle $S^1$ acts on a spin manifold, then the equivariant $\hat{A}$-genus is a formal difference of two finite dimensional vector spaces (positive and negative harmonic spinors) which are representation spaces of $S^1$. Our theorem (published in 1970) states that the difference of the characters of these representations (a finite Laurent series) is a constant, indeed equal to zero if the action is non-trivial. The proof uses the Atiyah-Singer equivariant index and fixed point theorem applied to the $S^1$-action. The rigidity theorem in the case of the equivariant universal elliptic genus of spin manifolds with $S^1$-action was first proved by Taubes and then by Bott and Taubes. I did not know it during the time of my course. I stressed special cases (strict multiplicativity in certain fibre bundles) following the pioneers Ochanine and Landweber.

Shortly after my course the proceedings of a Princeton meeting (1986) edited by Landweber became available. They give an excellent description of the history of the young theory and the state of the art around the time of my course.

During the second part of the course (changing the original program) I began to develop the theory of elliptic genera of level $N$ for complex manifolds, finding out that the differential equations for the characteristic functions are given by polynomials which I called almost-Chebyshev. These are polynomials such that the critical values except one are all equal up to sign. A little later I learned from Th. J. Rivlin that such polynomials were already well-known under the name Zolotarev polynomials. The universal elliptic
genus of level $N$ is a modular form for $\Gamma_1(N)$, the values in the cusps being certain holomorphic Euler numbers (if the first Chern class of the manifold is divisible by $N$). In this way the universal elliptic genus of level $N$ is very close to the Riemann-Roch theorem formulated and proved in my book mentioned above.

During the winter term 1987/88 I was occasionally away on official business. My course was taken over several times by N.-P. Skoruppa who gave a thorough and expert presentation of results on modular forms needed for the theory. P. Baum was visiting the Max-Planck-Institut. He also lectured in my course and gave an introduction to the Dirac operator. In this way the first two of the four appendices of this book came into existence.

The course was directed to students after their Vordiplom. Some of them had basic knowledge on characteristic classes. However, I tried to explain without proofs all the prerequisite material to make the course understandable to a large audience: characteristic classes, cobordism theory, Atiyah-Singer index theorem, Riemann-Roch theorem, etc.

Thomas Berger and Rainer Jung belonged to the students and prepared notes. This was a considerable job, because I did not have a usable manuscript. The result of their efforts were unofficial lecture notes in German which became ready in July 1988. P. Landweber used this notes for a course at Rutgers University in the spring of 1989 and prepared a translation into English for his students; in addition he proposed numerous corrections and improvements. Thus the present English text materialized. For the German version of the notes also Gottfried Barthel and Michael Puschnigg contributed improvements.

The book has two further appendices:

In August 1987 the sixteenth of the well-known and highly estimated International Conferences on Differential Geometrical Methods in Theoretical Physics organized by Konrad Bleuler took place in Como. I was invited to write up my talk for the proceedings. The talk was a general survey on elliptic genera. Instead of writing this up, I wrote a paper "Elliptic genera of level $N$ for complex manifolds" which is reproduced here as Appendix III, incorporating some corrections and improvements by Thomas Berger. A rigidity theorem for the level $N$ genus is contained in the paper. It was proved during my visit in Cambridge (England) in March 1988 when I was a guest of Robinson College. When Michael Atiyah came to Bonn in February 1988 he explained to me Bott's approach to the rigidity for spin manifolds mentioned above and indicated its relationship to our old paper on the $A$-genus. (The Atiyah-Singer equivariant index and fixed point theorem is used.) We had further discussions in Oxford in March 1988, before I proved the result for the level $N$ case (consulting Bott's Cargèse lectures). Later the paper by Bott and Taubes became available.

The role of the Zolotarev polynomials was already pointed out. At the end of my paper I announced the plan to write a separate paper on these polynomials and their role for the elliptic genus. But, indeed, Rainer Jung took over. This became the topic of his Diplomarbeit, in which he carried out my plan and proved several other interesting theorems. His Appendix IV is a condensed version of the Diplomarbeit.
I wish to thank all the mathematicians mentioned above for their cooperation and help. I want to express special thanks to my coauthors Thomas Berger and Rainer Jung who wrote the original notes and to whom the book owes its existence. Many thanks are due to Peter Landweber for the translation and for all mathematical help. I am grateful that Nils-Peter Skoruppa and Paul Baum added their lectures to the book, and I must thank again Rainer Jung for adding his Diplomarbeiten and for much work during the final stages of the preparation of the manuscript. Many thanks are due also to Mrs. Iris Abdel Hafez of the Max-Planck-Institut for her excellent work in typesetting the manuscript.

1 Background

1.1 Cobordism Theory

R. Thom [Th54] and L.S. Pontrjagin introduced the concept of cobordism, in which equivalence classes of manifolds are provided with a ring structure.

Let $V$ be a compact, oriented, differentiable, $n$-dimensional manifold without boundary.

For an oriented manifold $W$ with boundary, $\partial W$ denotes its boundary with the induced orientation.

**Definition:** A manifold $V$ bounds ($V$ is bounded) in case there exists a compact, oriented, differentiable, $(n+1)$-dimensional manifold $W$ so that $\partial W = V$.

**Example:** $S^n$ bounds ($S^n = \partial B^{n+1}$).

Further manifolds which are boundaries are the complex projective spaces of odd dimension. In order to show this, we use the following

**Lemma:** There exists a fibration $\sigma : P_{2k+1}(\mathbb{C}) \to P_k(\mathbb{H})$ with fibre $P_1(\mathbb{C})$. (Here $\mathbb{H}$ denotes the skew-field of quaternions.)

**Proof:** The bijection $\hat{\sigma} : \mathbb{C}^{2k+2} \to \mathbb{H}^{k+1},$

$$\hat{\sigma}(z_1, \ldots, z_{2k+2}) = (z_1 + z_2 \cdot j, \ldots, z_{2k+1} + z_{2k+2} \cdot j),$$

is compatible with left multiplication by complex scalars, and thereby induces the desired fibration $\sigma$.

The vectors $(z_1, \ldots, z_{2k+2})$ and $(z_2, -z_1, \ldots, z_{2k+2}, -z_{2k+1})$ span a plane in $\mathbb{C}^{2k+2}$, i.e. their images generate a projective line in $P_{2k+1}(\mathbb{C})$. Since $-j \cdot (z_1 + z_2 \cdot j) = z_2 - z_1 \cdot j$ holds in $\mathbb{H}$, this line is mapped to a point of $P_k(\mathbb{H})$ under $\sigma$, and on dimensional grounds is precisely the fibre.

**Proposition:** $P_{2k+1}(\mathbb{C})$ bounds.

**Idea of proof:** The above fibration yields a locally trivial fibre bundle with fibre $P_1(\mathbb{C}) \cong S^2$, which one can give the structure group $SO(3)$. One can extend its operation to the associated disk bundle (with fibre the 3-ball). This is then a manifold of dimension $4k+3$, whose boundary is exactly $P_{2k+1}(\mathbb{C})$.

**Definition:** Two manifolds $V$ and $W$ are called cobordant ($V \sim W$) in case the manifold $V + (-W)$ bounds. Here "+" denotes the disjoint union, and $-W$ is the manifold $W$ with reversed orientation.
1 Background

Remark: The relation \( \sim \) is an equivalence relation. The reflexivity follows from \( V + (-V) = \emptyset(V \times I) \), where \( I \) denotes the unit interval. It is elementary to verify the symmetry; for transitivity, one must glue two manifolds along diffeomorphic boundary components.

Definition: Let \( \Omega^n \) denote the set of equivalence classes of \( n \)-dimensional, compact, oriented, differentiable manifolds with respect to \( \sim \).

Remark: The pair \( (\Omega^n, +) \) is a finitely generated abelian group. The Cartesian product of manifolds induces a map \( \Omega^n \times \Omega^m \to \Omega^{n+m} \). Thereby \( \Omega = \sum_{n=0}^{\infty} \Omega^n \) becomes a graded commutative ring with 1, the so-called cobordism ring. Thus, one has \( \alpha \cdot \beta = (-1)^{n-m} \beta \cdot \alpha \) for \( \alpha \in \Omega^n, \beta \in \Omega^m \); the equivalence class of a point is the unit 1.

Theorem (Thom): \( \Omega^n \otimes \mathbb{Q} = 0 \) for \( 4 \nmid n \) and \( \Omega^{4k} \) is a finitely generated abelian group with rank equal to the number of partitions of \( k \).

Hence \( \Omega \otimes \mathbb{Q} \) is a commutative ring.

Definition: A sequence \( M^1, M^2, \ldots \) of manifolds (with \( \dim M^i = 4i \)) is called a basis sequence (of the cobordism ring) if \( \Omega \otimes \mathbb{Q} = \mathbb{Q}[M^1, M^2, \ldots] \), where the \( M^i \) are considered as equivalence classes.

Theorem: The spaces \( P_2(\mathbb{C}), P_4(\mathbb{C}), P_6(\mathbb{C}), \ldots \) form a basis sequence of \( \Omega \otimes \mathbb{Q} \), i.e.

\[
\Omega \otimes \mathbb{Q} = \mathbb{Q}[P_2(\mathbb{C}), P_4(\mathbb{C}), P_6(\mathbb{C}), \ldots]
\]

as a graded polynomial ring, where \( P_{4k}(\mathbb{C}) \) has weight (or dimension) \( 4k \).

Example:

\[
\begin{align*}
\Omega^2 & \otimes \mathbb{Q} = \langle P_2(\mathbb{C}) \rangle, \\
\Omega^4 & \otimes \mathbb{Q} = \langle P_2(\mathbb{C}) \times P_2(\mathbb{C}), P_4(\mathbb{C}) \rangle, \\
\Omega^6 & \otimes \mathbb{Q} = \langle P_2(\mathbb{C}) \times P_2(\mathbb{C}) \times P_2(\mathbb{C}), P_4(\mathbb{C}) \times P_2(\mathbb{C}), P_6(\mathbb{C}) \rangle.
\end{align*}
\]

1.2 Characteristic classes

Theorem: For each complex vector bundle \( E \) over a manifold \( X \) there exist Chern classes \( c_i(E) \) with:

1) \( c_i(E) \in H^{2i}(X; \mathbb{Z}), \ c_0(E) = 1, \)
\( c(E) := \sum_{i=0}^{\infty} c_i(E) \in H^*(X; \mathbb{Z}) \),

2) \( c_i(f^*E) = f^*c_i(E) \),

3) \( c(E \oplus F) = c(E) \cdot c(F) \),

4) \( c(H) = 1 - g \).
1.2 Characteristic classes

The Chern classes are uniquely determined by the properties 1) to 4).

Remarks:

On 1): One has $c_i(E) = 0$ for $i > \text{rk } E$, and $c(E)$ is called the total Chern class of $E$.

On 2): Let $f : Y \to X$ be a continuous map. Then $f^* E$ denotes the pulled-back bundle. This has as total space

$$\tilde{E} = \{(y, e) \in Y \times E \mid \pi(e) = f(y)\},$$

and one has the following diagram

$$\begin{array}{ccc}
E & \xrightarrow{\pi} & X \\
pr_i \downarrow & & \downarrow f \\
Y & \xrightarrow{f} & X
\end{array}$$

where $\text{pr}_i$ is the projection onto the $i$-th component. On the right side of the equation $f^*$ denotes the usual mapping $f^* : H^*(X; \mathbb{Z}) \to H^*(Y; \mathbb{Z})$.

On 3): Let $E$ and $F$ be two vector bundles over $X$. Then $E \oplus F$ is the Whitney sum of the bundles. The fibre $(E \oplus F)_x$ over a point $x \in X$ is the direct sum of the fibres $E_x$ and $F_x$ of $E$, resp. $F$. The multiplication rule therefore gives:

$$c_1(E \oplus F) = c_1(E) + c_1(F),$$

$$c_2(E \oplus F) = c_2(E) + c_1(E) \cdot c_1(F) + c_2(F) \text{ etc.}$$

On 4): Here $g \in H^2(P_n(\mathbb{C}); \mathbb{Z})$ denotes the generating element of the cohomology ring of $P_n(\mathbb{C})$, Poincaré dual to the homology class of the hyperplane $P_{n-1}(\mathbb{C}) \subset P_n(\mathbb{C})$. The bundle $H$ is the Hopf bundle or tautological bundle over $P_n(\mathbb{C})$, having as fibre over each point of $P_n(\mathbb{C})$ the line in $\mathbb{C}^{n+1}$ represented by it.

A differentiable manifold is called almost complex if its tangent bundle is derived from a complex bundle (by forgetting the complex structure).

**Theorem:** Let $X$ be an almost complex manifold of complex dimension $n$. Then the $n$-th Chern class $c_n = c_n(TX) \in H^{2n}(X; \mathbb{Z})$ satisfies $c_n[\Sigma X] = e(X)$, where $e(X)$ is the Euler number of $X$ (and $c_n[\Sigma X]$ denotes the evaluation of $c_n$ on the fundamental cycle of the oriented manifold $X$).

By the total Chern class of an almost complex manifold one means the total Chern class of its tangent bundle. With this convention we formulate the

**Lemma:** $c(P_n(\mathbb{C})) = (1 + g)^{n+1} = 1 + (n + 1) \cdot g + \binom{n+1}{2} g^2 + \cdots + (n + 1) \cdot g^n$.

**Proof:** Exercise, apply the above theorem (cf. [MiSt74], §14).

**Definition:** Let $E$ be a real vector bundle over $X$. Then we define the Pontrjagin classes $p_i(E)$ by

$$p_i(E) := (-1)^i c_{2i}(E \otimes \mathbb{C}) \in H^{4i}(X; \mathbb{Z}).$$
Proposition: Let $E$ be a real vector bundle over $X$ of rank $n$. Then the Pontrjagin classes satisfy the following axioms:

1) $p_i(E) \in H^{4i}(X; \mathbb{Z})$, $p_0(E) = 1$,
$$ p(E) := \sum_{i=0}^{\infty} p_i(E) \in H^*(X; \mathbb{Z}), $$
2) $p_i(f^*E) = f^*p_i(E)$,
3) $p(E \oplus F) = p(E) \cdot p(F)$ modulo 2-torsion,
4) $p(H_R) = 1 + g^2$.

Remarks:

On 1): One has $p_i(E) = 0$ for $2i > n$.
On 3): “modulo 2-torsion” means $2 \cdot (p(E \oplus F) - p(E) \cdot p(F)) = 0$.
On 4): For a complex bundle $F$, we denote by $F_R$ the underlying real bundle, i.e. $F$ as a real bundle when one forgets the complex vector space structure on the fibres.

Proof of the proposition: 1) and 2) are clear.

Since the complex bundle $E \otimes \mathbb{C}$ comes from a real bundle, one has $E \otimes \mathbb{C} \cong E \otimes \overline{\mathbb{C}}$. As we shall see in section 1.5, this implies for the Chern classes that

$$ c_{2i+1}(E \otimes \mathbb{C}) = c_{2i+1}(\overline{E \otimes \mathbb{C}}) = \begin{cases} 0 & \text{for } 2i > n, \\ (-1)^{2i+1} c_{2i+1}(E \otimes \mathbb{C}) & \text{for } 2i \leq n. \end{cases} $$

From this 3) is immediate.

Property 4) holds, since for a complex vector bundle $E$ always $E_R \otimes \mathbb{C} \cong E \otimes \overline{E}$. This is clear, since one can always conjugate a matrix of the form $$ \begin{pmatrix} \Re(z) & -\Im(z) \\ \Im(z) & \Re(z) \end{pmatrix} $$ into the form $$ \begin{pmatrix} a & -b \\ b & a \end{pmatrix} $$ canonically. Hence for a complex vector bundle $E$ one has

$$ \sum_{i=0}^{\infty} (-1)^i p_i(E) = c(E) \cdot \sum_{i=0}^{\infty} (-1)^i c_i(E). $$

For the Hopf bundle $H$ this means:

$$ 1 - p_1(H_R) = (1 + c_1(H)) \cdot (1 - c_1(H)) $$
$$ \quad \cdot = (1 - g) \cdot (1 + g) = 1 - g^2 $$
$$ \Rightarrow \quad p(H_R) = 1 + p_1(H_R) = 1 + g^2. $$

Analogously, one obtains for the projective spaces, noting that $(1 + g)^{n+1} \cdot (1 - g)^{n+1} = (1 - g^2)^{n+1}$, the result:

$$ p(P_n(\mathbb{C})) = (1 + g^2)^{n+1}. $$
1.3 Pontrjagin classes of quaternionic projective spaces

**Definition:** Let $X$ be a compact, oriented, almost complex manifold of dimension $2n$ and $(i_1, \ldots, i_r)$ a partition of $n$, i.e. $\sum_{j=1}^r i_j = n$. Then the Chern number corresponding to this partition is defined as

$$\left( \prod_{j=1}^r c_{i_j}(X) \right)[X].$$

In the differentiable case, one defines **Pontrjagin numbers** for a manifold of dimension $4n$ analogously as

$$\left( \prod_{j=1}^r p_{i_j}(X) \right)[X].$$

As we shall see in section 1.6, the Pontrjagin numbers are cobordism invariants. More precisely, there holds the following

**Theorem** (Thom): Two manifolds represent the same class in $\Omega \otimes \mathbb{Q}$ precisely when all their Pontrjagin numbers coincide.

### 1.3 Pontrjagin classes of quaternionic projective spaces

Analogous to the cell decomposition of complex projective space $\mathbb{P}^n(\mathbb{C}) = \mathbb{C}^n \cup \mathbb{P}^{n-1}(\mathbb{C})$, one obtains a cell decomposition of $\mathbb{P}^n(\mathbb{H})$ into cells of dimension $0, 4, 8, \ldots, 4n$. There further holds $H^4(\mathbb{P}^n(\mathbb{H}); \mathbb{Z}) = \mathbb{Z}[u]/(u^{n+1})$, where $u$ is a generator of $H^4(\mathbb{P}^n(\mathbb{H}); \mathbb{Z})$.

**Theorem** (Hirzebruch):

$$p(\mathbb{P}^n(\mathbb{H})) = (1 + u)^{2n+2} \cdot (1 + 4u)^{-1}$$

$$= (1 + u)^{2n+2} \cdot (1 - 4u + 16u^2 - 64u^3 + \cdots).$$

**Proof** (cf. [Hi53]): Let $\sigma : \mathbb{P}^{2k+1}(\mathbb{C}) \to \mathbb{P}^k(\mathbb{H})$ be the fibre bundle of section 1.1 with fibre $\mathbb{P}^k(\mathbb{C})$. Now (by the Leray-Hirsch theorem) $\sigma^* : H^4(\mathbb{P}^k(\mathbb{H}); \mathbb{Z}) \to H^{4r}(\mathbb{P}^{2k+1}(\mathbb{C}); \mathbb{Z})$ is an isomorphism for all $r$. We choose $u$ so that $\sigma^*(u) = g^2 \in H^4(\mathbb{P}^{2k+1}(\mathbb{C}); \mathbb{Z})$ then $u^k[\mathbb{P}^k(\mathbb{H})] = 1$ determines the orientation of $\mathbb{P}^k(\mathbb{H})$. The tangent bundle $\mathcal{T}$ of the projective space $\mathbb{P}^{2k+1}(\mathbb{C})$ splits into the direct sum of the sub-bundle $E$ along the fibres of the map $\sigma$ and the pullback of the tangent bundle $T$ of the projective space $\mathbb{P}^k(\mathbb{H})$:

$$\mathcal{T} = E \oplus \sigma^* T$$

$$\Rightarrow (1 + g^2)^{2k+2} = p(\mathcal{T}) = p(E) \cdot p(T).$$
The bundle $E$ is orientable, and so comes from a complex line bundle $(SO(2) \cong U(1))$. Notice that the restriction of this complex bundle to a fibre is $TP_1(C)$. The map $i : P_1(C) \to P_{2k+1}(C)$ induces on the cohomology level the identity in dimensions 0, 1 and 2, otherwise is the zero map. To see this, one considers a cell decomposition of $P_{2k+1}(C)$ into affine subspaces, which contains a cell decomposition of the fibre $P_1(C)$. Hence

$$i^* c_1(E) = c_1(i^*E) = c_1(P_1(C)).$$

Since $c_1(P_1(C))[P_1(C)] = e(S^2) = 2$, we have

$$c_1(E) = 2g$$
$$c(E) = 1 + 2g$$
$$1 - p_1(E) = (1 + 2g) \cdot (1 - 2g)$$
$$p(E) = 1 + p_1(E) = 1 + 4g^2.$$

Therefore

$$(1 + g^2)^{2k+2} = (1 + 4g^2) \cdot \sigma^*(p(T))$$
$$\Rightarrow \quad \sigma^*(p(T)) = (1 + g^2)^{2k+2} \cdot (1 + 4g^2)^{-1}.$$

Since $\sigma^*$ is an isomorphism in all dimensions $4r$, we have

$$p(T) = (1 + u)^{2k+2} \cdot (1 + 4u)^{-1}.$$  (***)

**Example:** The first Pontrjagin class of $P_n(\mathbb{H})$ is $p_1(P_n(\mathbb{H})) = (2n + 2) \cdot u - 4 \cdot u = (2n - 2) \cdot u$.

For $n = 1$ it follows that $p_1 = 0$, hence $p(P_1(\mathbb{H})) = p(S^4) = 1$.

**Definition:** A bundle $E$ is called stably trivial if a trivial bundle $F$ exists so that $E \oplus F$ is also trivial.

**Remark:** For a stably trivial bundle $E$ one has $p(E) = 1$. For

$$1 = c((E \oplus F) \otimes \mathbb{C}) = c(E \otimes \mathbb{C}) \cdot c(F \otimes \mathbb{C}) = c(E \otimes \mathbb{C})$$
$$\Rightarrow \quad p_i(E) = (-1)^i c_{2i}(E \otimes \mathbb{C}) = 0 \quad \text{for } i = 1, \ldots, n.$$

**Example:** The normal bundle $NS^k$ of the sphere $S^k$ is trivial, and also $TS^k \oplus NS^k = T\mathbb{R}^{k+1}|_{S^k}$. Therefore the tangent bundle of $S^k$ is stably trivial. Hence we have also given a direct calculation of the Pontrjagin classes of $P_1(\mathbb{H}) = S^4$.

For even $k$, there exists no nowhere vanishing vector field on $S^k$ (for $k$ even, the Euler number is $e(S^k) = 2 \neq 0$). Therefore the tangent bundle is then non-trivial. For odd $k$, this is also valid for $n \neq 1, 3, 7$, although difficult (cf. [Mi58] and [AdHi61b]). These three exceptional cases correspond to the existence of the real division algebras $\mathbb{C}$, $\mathbb{H}$ and the Cayley numbers.
Remark: The Pontrjagin classes are fixed under each automorphism of a differentiable manifold, since an automorphism of the tangent bundle is induced.

Example: For $k > 1$ there is no automorphism of $P_k(\mathbb{H})$ carrying $u$ to $-u$, since $p_1(P_k(\mathbb{H})) = (2k - 2) \cdot u \neq 0$. For $k = 1$ there exists the antipodal map $S^4 \to S^4, x \mapsto -x$.

1.4 Characteristic classes and invariants

The following is intended to provide motivation for why the Chern resp. Pontrjagin classes will be regarded formally as elementary symmetric functions, and why they yield important information on the isomorphism class of a bundle. For a more detailed treatment of this so-called splitting principle we refer to section 4.4.

A complex line bundle over $X$ has structure group $\mathbb{C}^*$; the first Chern class $c_1 \in H^2(X; \mathbb{Z})$ yields an isomorphism from the group of isomorphism classes of line bundles with tensor product as group operation onto the second integral cohomology: Let $E$ and $F$ be two line bundles over $X$, and $X = \bigcup_i U_i$ a common system of local trivializations with change of coordinates $e_{ij}$, resp. $f_{ij} : U_i \cap U_j \to \mathbb{C}^*$. Then $(p, z)$ in the chart $U_j \times \mathbb{C}$ is to be identified with $(p, e_{ij} \cdot z)$, resp. $(p, f_{ij} \cdot z)$ in $U_i \times \mathbb{C}$, and the $e_{ij}$, resp. $f_{ij}$ satisfy the cocycle condition $e_{ij} \cdot e_{jk} = e_{ik}$, resp. $f_{ij} \cdot f_{jk} = f_{ik}$. Because of the commutativity of the structure group $\mathbb{C}^*$, the products $e_{ij} \cdot e_{ij}$ also satisfy the cocycle condition, and so define a line bundle $E \otimes F$, the tensor product of $E$ and $F$.

Let now $E = E_1 \oplus \cdots \oplus E_n$ be a direct sum of complex line bundles, $x_i = c_1(E_i) \in H^2(X; \mathbb{Z})$, and let $\mathbb{Z}[x_1, \ldots, x_n] \subset H^*(X; \mathbb{Z})$ be the subring generated by the $x_i$. The complex vector bundle $E_1 \oplus \cdots \oplus E_n$ has rank $n$ and total Chern class

$$c(E) = 1 + c_1 + \cdots + c_n = (1 + x_1) \cdots (1 + x_n).$$

Therefore $c_r = \sigma_r(x_1, \ldots, x_n)$ is the $r$-th elementary symmetric function in the $x_i$ (by a comparison of dimensions of cohomology classes).

If one introduces a Hermitian metric on $E_i$, then the structure group of $E_i$ can be reduced to $U(1) \cong S^1$; that of their direct sum $E$ can therefore be reduced to

$$T^n = S^1 \times \cdots \times S^1 = \{ A \in U(n) \mid A = \begin{pmatrix} e^{2\pi i \varphi_1} & & \\ & \ddots & \\ & & e^{2\pi i \varphi_n} \end{pmatrix}, \varphi_i \in \mathbb{R} \}.$$

This torus $T^n \subset U(n)$ is maximal in the compact connected Lie group $U(n)$. Let $G$ be a compact connected Lie group, then there holds for the maximal tori in $G$ the following

Theorem: Each element of $G$ lies in a maximal torus. If $T, T'$ are maximal tori, then there exists a $g \in G$ so that $gTg^{-1} = T'$ (cf. [HoSa40]).
This theorem is a generalization of the principal axis theorem of linear algebra: since each element lies in some maximal torus, it can be conjugated into the standard maximal torus $T^n$.

An element $g \in U(n)$ with $gTg^{-1} = T$ transports the different $S^1$-components of the torus into one another, and so yields an isomorphism of the $U(n)$-bundle which permutes the summands $E_i$, but need not be an isomorphism of $T^n$-bundles. Hence, each expression invariant under $U(n)$-isomorphism must remain fixed under permutations of the $x_i$, i.e. is a polynomial in the Chern classes $c_j$, since these are the elementary symmetric functions $\sigma_j(x_1, \ldots, x_n)$ in the $x_i$.

For Pontrjagin classes the analog holds: Let $E$ be a real vector bundle of rank $2n$ and with structure group $SO(2n)$. The standard maximal torus is

$$T^n = \{ A \in SO(2n) \mid A = \begin{pmatrix} R(2\pi \varphi_1) & & \vdots \\ & \ddots & \\ & & R(2\pi \varphi_n) \end{pmatrix}, \varphi_i \in \mathbb{R} \},$$

where $R(2\pi \varphi) = \begin{pmatrix} \cos(2\pi \varphi) & -\sin(2\pi \varphi) \\ \sin(2\pi \varphi) & \cos(2\pi \varphi) \end{pmatrix}$. Assume that the structure group is reduced to $T^n \subset SO(2n)$. Then we know that the vector bundle $E$ is a direct sum of two-dimensional bundles $E_i$ with structure group $SO(2) \cong U(1) \cong S^1$, thus $E = E_1 \oplus \cdots \oplus E_n$, and we define $x_i := c_1(E_i)$.

Elements $g \in SO(2n)$ with $gTg^{-1} = T$ yield arbitrary exchanges of the $E_i$ with an even number of orientation changes of the $E_i$, without altering the isomorphism type of the $SO(2n)$-bundle $E$. Thus, the ring of invariant polynomials has generators $\sigma_j(x_1^2, \ldots, x_n^2)$ and $x_1 \cdots x_n$. Since

$$p(E) = p(E_1) \cdots p(E_n) = (1 + x_1^2) \cdots (1 + x_n^2),$$

$p_j = \sigma_j(x_1^2, \ldots, x_n^2)$ and $e = x_1 \cdots x_n$ generate the ring of invariants ($e$ is called the Euler class and one has $e(TX)[X] = e(X)$, the Euler number of the manifold $X$).

Now let the rank of $E$ be $2n+1$, the structure group $SO(2n+1)$, with maximal torus

$$T^n = \{ A \in SO(2n+1) \mid A = \begin{pmatrix} R(2\pi \varphi_1) & & \vdots \\ & \ddots & \\ & & R(2\pi \varphi_n) \end{pmatrix}, \varphi_i \in \mathbb{R} \}.$$ 

In this case an odd number of orientation changes of the $E_i$ is also possible, because an odd permutation can be compensated by $-1$ in the lower corner of the permutation matrix. In odd dimensions the Euler class is therefore no longer invariant; the Pontrjagin classes $p_j = \sigma_j(x_1^2, \ldots, x_n^2)$ generate the ring of invariant polynomials.

Each polynomial which is symmetric in the $x_i^2$ can be expressed in the $p_j$; for example,

$$\sum_{i=1}^n x_i^4 = p_1, \quad \sum_{i=1}^n x_i^4 = p_1^2 - 2p_2.$$
1.5 Representations and vector bundles

Let $E$ be a complex vector bundle of rank $n$ over a differentiable manifold $X$. Assume that the structure group of $E$ is reduced to $U(n)$. Let $\rho$ be a unitary representation of $U(n)$ of dimension $m$, so that $\rho : U(n) \to U(m)$ is a homomorphism. The group $U(n)$ then acts on $\mathbb{C}^m$ by means of $\rho$. We consider the vector bundle $\rho E$, associated to $E$, with fibre $\mathbb{C}^m$.

Examples: By suitable choices of $\rho$ one obtains for $\rho E$ the bundles:

1) $E^* \cong \overline{E}$ with rank $n$ for $\rho(U) = \overline{U}$,
2) $\Lambda^k E$ with rank $\binom{n}{k}$ for $\rho(U) (v_1 \wedge \cdots \wedge v_k) = U v_1 \wedge \cdots \wedge U v_k$ where $v_1 \wedge \cdots \wedge v_k \in \Lambda^k \mathbb{C}^n$,
3) $S^k E$ with rank $\binom{n+k-1}{k}$ for $\rho(U) (v_1 \otimes \cdots \otimes v_k) = U v_1 \otimes \cdots \otimes U v_k$ where $v_1 \otimes \cdots \otimes v_k \in S^k \mathbb{C}^n$.

Let the bundle $E$ have Chern classes $c_j(E) \in H^{2j}(X; \mathbb{Z})$. We want to express the Chern classes of the bundle $\rho E$ in terms of the $c_j(E)$. For this, we consider a formal factorization of the total Chern class

$$c(E) = 1 + c_1(E) + \cdots + c_n(E) = (1 + x_1) \cdots (1 + x_n),$$

i.e. $c_j(E)$ is the $j$-th elementary symmetric function $\sigma_j(x_1, \ldots, x_n)$ in the $x_i$. All expressions which are symmetric in the formal roots $x_i$ of $c(E)$ are well-defined, since they can be expressed in terms of the $c_j(E)$. Thus, we can define the Chern character $\text{ch}(E)$ of the bundle $E$ as

$$\text{ch}(E) = \sum_{i=1}^{n} e^{x_i};$$

$$= n + \sum_{i=1}^{n} x_i + \frac{1}{2} \sum_{i=1}^{n} x_i^2 + \frac{1}{6} \sum_{i=1}^{n} x_i^3 + \cdots$$

$$= n + c_1 + \frac{c_1^2 - 2c_2}{2} + \frac{c_1^3 - 3c_1c_2 + 3c_3}{6} + \cdots \in H^*(X; \mathbb{Q}).$$

Conversely, $\text{ch}(E)$ determines the rational Chern classes of $E$ ($c_j$ can be expressed in terms of the cohomology components of dimension up to $2j$ of $\text{ch}(E)$). For a trivial bundle $E$ of rank $n$, one has $\text{ch}(E) = n$. The Chern character of $E$ has two beautiful properties:

$$\text{ch}(E_1 \oplus E_2) = \text{ch}(E_1) + \text{ch}(E_2) \quad \text{and} \quad \text{ch}(E_1 \otimes E_2) = \text{ch}(E_1) \cdot \text{ch}(E_2).$$

For a representation $\rho : U(n) \to U(m)$, we define its character $\text{char}(\rho) : U(n) \to \mathbb{C}$ as the trace of $\rho A$: $\text{char}(\rho)(A) := \text{tr}(\rho A)$ for all $A \in U(n)$. Now the standard maximal tori in $U(n)$, resp. $U(m)$, are

$$T = \{ A \in U(n) \mid A = \begin{pmatrix} e^{2\pi i x_1} & & \\ & \ddots & \\ & & e^{2\pi i x_n} \end{pmatrix}, x_i \in \mathbb{R} \}.$$
and
\[ \tilde{T} = \{ A \in U(m) \mid A = \begin{pmatrix} e^{2\pi i y_1} & \cdots & \cdots & e^{2\pi i y_m} \end{pmatrix}, y_i \in \mathbb{R} \}. \]

Since \( \rho(T) \) is again abelian, and therefore lies in a maximal torus, and since any two maximal tori are conjugate, we can change \( \rho \) (by conjugation in \( U(m) \)) to an equivalent representation for which \( \rho(T) \subset \tilde{T} \). Since conjugation of transition functions carries a bundle to an isomorphic bundle, the isomorphism class of \( \rho(E) \) does not change, nor do its Chern classes. In \( \rho(T) \subset \tilde{T} \) there holds
\[ y_r(x_1, \ldots, x_n) = \sum_{s=1}^{n} a_{rs}x_s \quad \text{with} \quad a_{rs} \in \mathbb{Z}. \]

One calls the \( y_r = (a_{r1}, \ldots, a_{rn}) \) the weights of the representation (interpreted as linear forms), and obtains for the character of the representation \( \rho \):
\[ \text{char} \left( \rho \right)|_T = \sum_{r=1}^{m} e^{2\pi i y_r}. \]

For the bundle \( \rho E \) associated to \( E \) then holds (cf. [BoHi58]) the

**Theorem:** \( \text{ch} \left( \rho E \right) = \sum_{r=1}^{m} e^{y_r} \quad \text{and} \quad \text{c}(\rho E) = \prod_{r=1}^{m} (1 + y_r). \)

**Remark:** More precisely, in place of \( y_r \) one must write \( y_r(x_1, \ldots, x_n) \), where again \( c_j(E) = \sigma_j(x_1, \ldots, x_n) \).

**Example:** In case \( E = L_1 \oplus \cdots \oplus L_n \) is a sum of line bundles, \( x_i = c_1(L_i) \) and \( y_r = \sum_{s=1}^{n} a_{rs}x_s \), one has:
\[ \rho(E) = (L_1^{a_{11}} \otimes \cdots \otimes L_n^{a_{1n}}) \oplus \cdots \oplus (L_1^{a_{m1}} \otimes \cdots \otimes L_n^{a_{mn}}) \]
\[ \Rightarrow \quad \text{c}(\rho E) = \prod_{r=1}^{m} (1 + a_{r1}c_1(L_1) + \cdots + a_{rn}c_1(L_n)) \]
\[ = \prod_{r=1}^{m} (1 + y_r) \]
\[ \Rightarrow \quad \text{ch} \left( \rho E \right) = \sum_{r=1}^{m} e^{y_r}. \]

**Remark:** This is even a proof of the above theorem, if one uses the following meta-principle (the splitting principle, cf. section 4.4): All identities for Chern classes of vector bundles that one can prove by means of the formal factorization of the total Chern class are true.
Examples: For our special representations at the start of this section we obtain:

1) For $pE = E^*$:

$$y_i = -x_i$$
and
$$c(E^*) = \prod_{i=1}^{n} (1 - x_i) = \sum_{i=1}^{n} (-1)^i c_i(E).$$

2) For $pE = \Lambda^k E$:

$$y_{i_1, \ldots, i_k} = x_{i_1} + \cdots + x_{i_k}$$
and
$$c(\Lambda^k E) = \prod_{1 \leq i_1 < \cdots < i_k \leq n} (1 + (x_{i_1} + \cdots + x_{i_k})).$$

3) For $pE = S^k E$:

$$y_{i_1, \ldots, i_k} = x_{i_1} + \cdots + x_{i_k}$$
and
$$c(S^k E) = \prod_{1 \leq i_1 \leq \cdots \leq i_k \leq n} (1 + (x_{i_1} + \cdots + x_{i_k})).$$

4) For $pE = \Lambda^k E^*$:

$$y_{i_1, \ldots, i_k} = -(x_{i_1} + \cdots + x_{i_k})$$
and
$$c(\Lambda^k E^*) = \prod_{1 \leq i_1 < \cdots < i_k \leq n} (1 - (x_{i_1} + \cdots + x_{i_k})).$$

The Chern character therefore satisfies the following formula:

$$\sum_{k=0}^{n} \text{ch}(\Lambda^k E^*) \cdot t^k = \prod_{i=1}^{n} (1 + te^{-x_i}).$$

In view of the additivity and multiplicativity of the Chern character, we will also denote this expression by

$$\text{ch} \left( \sum_{k=0}^{\infty} (\Lambda^k E^*) \cdot t^k \right).$$

With the abbreviation

$$\Lambda t E := \sum_{k=0}^{\infty} (\Lambda^k E) \cdot t^k$$

we have more simply

$$\text{ch} (\Lambda t E^*) = \prod_{i=1}^{n} (1 + te^{-x_i}).$$
1 Background

For a trivial bundle of rank $n$ this is the well-known formula:

$$\sum_{k=0}^{n} (\binom{n}{k}) \cdot t^k = (1 + t)^n = \prod_{i=1}^{n} (1 + t).$$

Analogously, there holds for the symmetric powers, with the notation

$$S_tE := \sum_{k=0}^{\infty} (S^k E) \cdot t^k$$

the formula

$$\text{ch}(S_tE^*) = \prod_{i=1}^{n} \frac{1}{1 - te^{-x_i}}.$$

For a trivial bundle this becomes

$$\sum_{k=0}^{\infty} (\binom{n+k-1}{k}) \cdot t^k = \sum_{k=0}^{\infty} (-1)^k t^k = (1 - t)^{-n} = \prod_{i=1}^{n} \frac{1}{1 - t}.$$

Now let $E$ be a real vector bundle of rank $2n$ over $X$, having structure group reduced to $SO(2n)$. The bundle $E$ has characteristic classes $p_i(E) \in H^{4i}(X; \mathbb{Z})$ and $e(E) \in H^{2n}(X; \mathbb{Z})$.

To each homomorphism $\rho : SO(2n) \to U(m)$ one again obtains a bundle $\rho E$ associated to $E$, as well as by analogy to the above the character $\text{char}(\rho)$ and the weights $y_r$ with respect to the standard tori, which we have already considered earlier. In this situation we have the analog of the above theorem:

**Theorem:** $\text{ch}(\rho E) = \sum_{r=1}^{m} e^{y_r}$ and $c(\rho E) = \prod_{r=1}^{m} (1 + y_r).

The total Pontrjagin class of $\Lambda^k E^* \otimes \mathbb{C}$ is calculated from the total Chern class of $\Lambda^k (E^* \otimes \mathbb{C})$. Since we already know the Chern classes of exterior powers, we need only consider the representation $\rho : SO(2n) \subset U(2n)$ with $\rho E = E \otimes \mathbb{C}$. For this representation, a box in the standard maximal torus of the form $R(2\pi x_r) = \begin{pmatrix} \cos(2\pi x_r) & -\sin(2\pi x_r) \\ \sin(2\pi x_r) & \cos(2\pi x_r) \end{pmatrix}$ goes over to the box $(e^{2\pi i x_r} \ 0 \ e^{-2\pi i x_r})$. The weights are therefore $\pm x_r$, and one obtains the

**Theorem:**

$$\text{ch}(\Lambda_t E^* \otimes \mathbb{C}) = \text{ch}\left( \sum_{k=0}^{n} (\Lambda^k (E^* \otimes \mathbb{C})) \cdot t^k \right) = \prod_{i=1}^{n} ((1 + te^{x_i}) \cdot (1 + te^{-x_i})).$$
1.6 Multiplicative sequences and genera

**Definition:** Let $R$ be an integral domain over $\mathbb{Q}$. Then a genus is a ring homomorphism $\varphi : \Omega \otimes \mathbb{Q} \rightarrow R$ with $\varphi(1) = 1$.

Let $Q(x) = 1 + a_2 x^2 + a_4 x^4 + \cdots$ be an even power series, starting with 1 and with coefficients in $R$. For indeterminates $x_i$ of weight two, where $1 \leq i \leq n$, the product $Q(x_1) \cdots Q(x_n)$ is symmetric in the $x_i^2$:

$$Q(x_1) \cdots Q(x_n) = 1 + a_2 \sum_{i=1}^{n} x_i^2 + \cdots$$

The term of weight $4r$ can therefore be expressed as a homogeneous polynomial $K_r(p_1, \ldots, p_r)$ of weight $4r$ in the elementary symmetric functions $p_j$ of the $x_i^2$, i.e.

$$Q(x_1) \cdots Q(x_n) = 1 + K_1(p_1) + K_2(p_1, p_2) + \cdots + K_n(p_1, \ldots, p_n) + K_{n+1}(p_1, \ldots, p_n, 0) + \cdots$$

where the polynomials $K_r$ for $1 \leq r \leq n$ do not depend on $n$. The sequence $\{K_r\}$ of polynomials $K_r$ is called the multiplicative sequence of polynomials associated to the power series $Q(x)$ (cf. [Hi56]). Now a genus $\varphi : \Omega \otimes \mathbb{Q} \rightarrow R$ is determined by the power series $Q(x)$, as follows:

**Definition:** The genus $\varphi_Q$ corresponding to a power series $Q$ is defined, for every compact, oriented, differentiable manifold $M$ of dimension $4n$, by

$$\varphi_Q(M) := K_n(p_1, \ldots, p_n)[M] \in R$$

with $p_i = p_i(M) \in H^{4i}(M; \mathbb{Z})$. In addition, we put $\varphi_Q(M) := 0$ if $4 \nmid n$. With

$$K(TM) := K(p_1, \ldots, p_n) := 1 + K_1(p_1) + K_2(p_1, p_2) + \cdots$$

and $K(M) := K(TM)[M]$, we have $\varphi_Q(M) = K(M)$. 

Analogously,

$$\text{ch} \left( S^1 E^* \otimes \mathbb{C} \right) = \text{ch} \left( \sum_{k=0}^{\infty} (S^k(E^* \otimes \mathbb{C})) \cdot t^k \right) = \prod_{i=1}^{n} \frac{1}{(1 - te^{xi})(1 - te^{-xi})}. \quad \blacksquare$$
The genus belonging to a power series is therefore a linear combination of Pontrjagin numbers. In case it is clear from which power series \( Q \) the genus has been formed, we shall frequently write \( \varphi \) in place of \( \varphi_Q \).

**Lemma:** Such a \( \varphi_Q \) is a well-defined genus.

**Proof:** To verify that \( \varphi \) is well-defined, it must be shown that \( \varphi \) vanishes on boundaries and is compatible with disjoint union and Cartesian product. Let \( M^{4n} = \partial W^{4n+1} \). Since the normal bundle of \( M^{4n} \) in \( W^{4n+1} \) is trivial, the tangent bundle of \( W^{4n+1} \) restricted to the boundary is equal to the tangent bundle of \( M^{4n} \) plus a trivial line bundle. The Pontrjagin classes of \( M^{4n} \) are therefore those of \( W^{4n+1} \) restricted to the boundary (stability of Pontrjagin classes). Hence the Pontrjagin numbers of \( M^{4n} \) are equal to 0 (by Stokes’s theorem).

The additivity of \( \varphi \) is clear. Now the multiplicative sequence \( \{K_d\} \) possesses a multiplicative property (hence the name):

If \( p_1, p'_1, p''_1 \) are indeterminates for which

\[
1 + p_1 + p_2 + \cdots = (1 + p'_1 + p'_2 + \cdots) \cdot (1 + p''_1 + p''_2 + \cdots)
\]

then one also has

\[
\sum_{n \geq 0} K_n(p_1, \ldots, p_n) = \sum_{n \geq 0} K_n(p'_1, \ldots, p'_n) \cdot \sum_{n \geq 0} K_n(p''_1, \ldots, p''_n).
\]

Exactly this assumption is fulfilled by the Pontrjagin classes of the cross product of two manifolds. As one now easily sees, \( \varphi \) is therefore also compatible with multiplication in the cobordism ring.

For an even normalized power series \( Q \) as above, let us now define \( f(x) := x/Q(x) \). This is an odd power series, beginning with \( x \) and with coefficients in \( R \) (in the formation of \( 1/Q(x) \), one again obtains a formal power series with coefficients in \( R \), since \( Q(x) \) begins with 1).

Put \( y = f(x) \) and \( g = f^{-1} \) as the (formal) inverse function, i.e. \( g(y) = x \). This power series \( g \) is also called the logarithm of the genus \( \varphi_Q \) (cf. section 3.1).

**Lemma:** \( g'(y) = \sum_{n=0}^{\infty} \varphi_Q(P_n(C)) \cdot y^n. \)

**Proof:**

\[
c(P_n(C)) = (1 + x)^{n+1}, \quad x \in H^2(P_n(C); \mathbb{Z}) \quad \text{(earlier; } x = g)\]
\[
\Rightarrow p(P_n(C)) = (1 + x^2)^{n+1} = (1 + p_1)^{n+1}
\]
\[
\Rightarrow K(p_1, \ldots, p_n) = K(p_1)^{n+1} = Q(x)^{n+1}.
\]
We now calculate $\varphi_Q(P_n(C))$ with the residue theorem and multiplicativity as follows:

\[
\varphi_Q(P_n(C)) = \left( \frac{x}{f(x)} \right)^{n+1} [P_n(C)]
\]

\[= \text{coefficient of } x^n \text{ in } \left( \frac{x}{f(x)} \right)^{n+1} = \text{res}_0 \left( \frac{x}{f(x)} \right)^{n+1} \frac{dx}{2\pi i} = \frac{1}{2\pi i} \int \frac{x}{f(x)}^{n+1} \frac{dx}{f(x)} = \frac{1}{y^{n+1}} \int g'(y) \frac{dy}{y^{n+1}} = \text{coefficient of } y^n \text{ in } g'(y).
\]

If $f$ converges, $\kappa$ corresponds to a circle about 0 in function theory; $f(\kappa)$ is then also a closed path with winding number one, since the power series $f$ starts with $x$. If $f$ doesn't converge the integral makes no sense but the substitution formula for residues of differentials holds for any formal power series $f$.

On the other hand, if one prescribes the values of a genus $\varphi$ on the complex projective spaces, therefore fixing the power series $g'$, then one immediately obtains the series $g$ and $f = g^{-1}$, and so also $Q(x) = x/f(x)$. Hence there is a one-to-one correspondence between genera and even power series $Q(x) = 1 + \cdots$. The power series $Q$ is also called the characteristic power series of $\varphi$.

**Example:** Let $Q(x) = x/\tanh(x)$, so $f(x) = \tanh(x)$. Then $f'(x) = 1 - f(x)^2$, so $g'(y) = 1/(1 - y^2) = 1 + y^2 + y^4 + \cdots$. One thereby obtains a genus, taking the value 1 on all $P_k(C)$, which is called the $L$-genus (cf. [Hi56]).

**Convention:** Since we shall not distinguish between a genus and the corresponding multiplicative sequence, let us agree as follows: For a manifold $M$, the value of the genus will be denoted by $\varphi(M)$; for a bundle $E$ over $M$, $\varphi(E)$ denotes the corresponding expression in the Pontrjagin classes of $E$. One therefore has $\varphi(M) = \varphi(TM)[M]$. 

**1.7 Calculation of $\varphi(P_k(H))$**

Using the fibre bundle $\sigma : P_{2k+1}(C) \to P_k(H)$ with fibre $F_k(C)$ and the identification of $g^2 \in H^4(P_{2k+1}(C);Z)$ with $u \in H^4(P_k(H);Z)$ by means of $\sigma^*$, we saw earlier that

\[\varphi(P_k(H)) = \left( 1 + g^2 \right)^{2k+2} \cdot (1 + 4g^2)^{-1}.
\]

Now let $\varphi$ be the genus corresponding to some power series $Q(x) = x/f(x)$. Then $\varphi(P_k(H))$ is the coefficient $a_{2k}$ of $x^{2k}$ in $\left( \frac{x}{f(x)} \right)^{2k+2} \cdot (\frac{f(2x)}{2})$. This is

\[
a_{2k} = \text{res}_0 \frac{f(2x)}{f(x)}^{2k+2} \cdot \frac{1}{2} \cdot \text{res}_0 \frac{f(2x)}{y^{2k+2}} = \text{res}_0 \frac{f(2x)}{2} g'(y) \frac{dy}{y^{2k+2}}.
\]
There exists an even power series $\tilde{h}(x)$ so that $f(2x) = 2f(x)f'(x)\tilde{h}(x)$. Then $h(y) := h(g(y))$ is an even power series with $f(2x) = 2f(x)f'(x)h(y)$, hence:

$$a_{2k} = \text{res}_0 \frac{2f(x)}{y^{2k+2}} f'(x)g'(y) h(y)\, dy$$

$$= \text{res}_0 \frac{1}{y^{2k+1}} h(y)\, dy \quad \text{(since } f(x) = y, f'(x) = 1/g'(y))$$

$$= \text{coefficient of } y^{2k} \text{ in } h(y).$$

We have therefore proved the

**Lemma:** $\sum_{k=0}^{\infty} \varphi(P_k(\mathbb{H})) y^{2k} = h(y)$, where $h(f(x)) = \frac{f(2x)}{2f(x)f'(x)}$.

**Examples:**

1) $Q(x) = \frac{x}{\sin(x)}$:

Then $f(x) = x/Q(x) = \sin(x)$ and $f(2x) = \sin(2x) = 2\sin(x)\cos(x) = 2\tilde{h}(x)f'(x)$, i.e. in this case $h \equiv 1$. The power series $f(x) = \sin(\alpha x)/\alpha$ are all those for which $h \equiv 1$ holds in the duplication formula. Therefore the corresponding genera $\varphi$ vanish on all projective spaces $P_k(\mathbb{H})$ with $k > 0$.

The genus corresponding to

$$Q(x) = \frac{x/2}{\sinh(x/2)}$$

is called the \(\hat{A}\)-genus, and the normalization is chosen so that for spin manifolds it is related to the index of an elliptic differential operator (the Dirac operator, cf. Appendix II).

2) $Q(x) = \frac{x}{\tanh(x)}$ (\(L\)-genus):

We have earlier calculated that $L(P_{2k}(\mathbb{C})) = 1$ for all $k$.

$$\tanh(2x) = \frac{2 \tanh(x)}{1 + \tanh(x)^2} = \frac{2 \tanh(x)(1 - \tanh(x)^2)}{1 - \tanh(x)^4}$$

$$= \frac{2 \tanh(x)}{1 - \tanh(x)^4}$$

$$\Rightarrow \ h(y) = \frac{1}{1 - y^4} = 1 + y^4 + y^8 + \cdots$$

$$\Rightarrow \ L(P_k(\mathbb{H})) = \begin{cases} 0, & k \equiv 1 \ (2), \\ 1, & k \equiv 0 \ (2). \end{cases}$$
One arrives at the so-called elliptic genera if one requires that in the duplication formula

$$h(y) = \frac{1}{1 - \epsilon \cdot y^4},$$

which gives

$$\varphi(P_k(\mathbb{H})) = \begin{cases} 0, & k \equiv 1 \ (2), \\ \epsilon^{k/2}, & k \equiv 0 \ (2). \end{cases}$$

The solution $f(x)$ to this kind of duplication formula is still not unique, rather it depends on a parameter $\delta$. The latter is the value of the genus on $P_2(\mathbb{C})$, i.e. $g'(y) = 1 + \delta y^2 + \cdots$. These genera are called elliptic genera because of the connection with elliptic functions; more about this later.

**Examples:** $\delta = \epsilon = 1$: $L$-genus; $\delta = -\frac{1}{6}, \epsilon = 0$: $\hat{A}$-genus.

Since in dimension four there is only the Pontrjagin number $p_1$ and $p_1(P_2(\mathbb{C})) = 3$, in this dimension one has $L = p_1/3$ and $\hat{A} = -p_1/24$.

**Exercise:** Let $f(x) = x + \cdots$ be an odd power series, $g'(y)$ the derivative of the inverse function with $g'(y) = 1 + \delta \cdot y^2 + \cdots$, and suppose further that

$$f(2x) = \frac{2f(x)f'(x)}{1 - \epsilon \cdot f(x)^4}.$$

For fixed $\delta, \epsilon$ this power series is uniquely determined. Use this to prove that

$$f(u + v) = \frac{f(u)f'(v) + f'(u)f(v)}{1 - \epsilon \cdot f(u)^2 f(v)^2}.$$

Deduce then that

$$f'^2 = 1 - 2\delta \cdot f^2 + \epsilon \cdot f^4.$$

Now we can make the following

**Definition:** A genus $\varphi$ is called an elliptic genus, if the corresponding power series $f(x) = x/Q(x)$ satisfies one of the three equivalent conditions:

1) $f'^2 = 1 - 2\delta \cdot f^2 + \epsilon \cdot f^4$,
2) $f(u + v) = \frac{f(u)f'(v) + f'(u)f(v)}{1 - \epsilon \cdot f(u)^2 f(v)^2}$,
3) $f(2u) = \frac{2f(u)f'(u)}{1 - \epsilon \cdot f(u)^4}$.
Examples: The two most important special cases are:

a) \( \delta = \epsilon = 1 \): \( f(x) = \tanh(x) \), \( g'(y) = \frac{1}{1-y^2} \).

1) \( f'^2 = (1 - y^2)^2 = (1 - f^2)^2 \).
2) Addition theorem for the hyperbolic tangent.

b) \( \delta = -\frac{1}{8}, \epsilon = 0 \): \( f(x) = 2 \sinh(x/2) \), \( g'(y) = (1 + \frac{1}{4} y^2)^{-1/2} \).

1) \( f'^2 = 1 + \frac{1}{4} y^2 = 1 + \frac{1}{4} f^2 \).
2) Addition theorem for the hyperbolic sine.

1.8 Complex genera

Similar to the construction of the real cobordism ring, one can define relations between stably almost complex manifolds and so obtain the complex cobordism ring (cf. [N062]). For this ring, complex genera are again defined simply as ring homomorphisms. Just as in the real case, there is a one-to-one correspondence between genera and power series \( Q(x) = 1 + b_1 x + \cdots \), but now these power series \( Q \) need no longer be even. Let \( X \) be a compact, almost complex manifold of real dimension \( 2n \). As usual, let

\[
c(X) = 1 + c_1(X) + \cdots + c_n(X) = (1 + x_1) \cdots (1 + x_n).
\]

Then the genus \( \varphi \) of \( X \), belonging to the power series \( Q \), is given by

\[
\varphi(X) = \left( \prod_{i=1}^{n} Q(x_i) \right)[X].
\]

Just as in the real case, one can associate to the power series \( Q \) a sequence of polynomials \( K_r(c_1, \ldots, c_r) \). Here the polynomial \( K_r \) is homogeneous of degree \( r \), if one assigns the degree \( j \) to the elementary symmetric function \( c_j \) in the \( x_i \). These polynomials have the property that

\[
\varphi(X) = K_n(c_1, \ldots, c_n)[X].
\]

For reasons of degree, \( c_n \) enters only linearly into \( K_n \). The coefficient of \( c_n \) is a fixed polynomial \( s_n \) in the coefficients \( b_j \) of the power series \( Q \). In order to determine this polynomial, we shall make use of a trick. Since \( s_n \) only depends on the terms of degree
at most $n$ in the power series $Q$, we can write formally

$$1 + b_1 x + \cdots + b_n x^n = \prod_{i=1}^{n} (1 + \beta_i x)$$

$$\Rightarrow \prod_{j=1}^{n} Q(x_j) = \prod_{j=1}^{n} \prod_{i=1}^{n} (1 + \beta_i x_j) \quad (x^{n+1})$$

$$= \prod_{i=1}^{n} \left( \prod_{j=1}^{n} (1 + \beta_i x_j) \right) \quad (x^{n+1})$$

$$= \prod_{i=1}^{n} (1 + \beta_i c_1 + \cdots + \beta_i^n c_n) \quad (x^{n+1}).$$

In order to determine $s_n$, we put $c_1 = \ldots = c_{n-1} = 0$. Since we must now consider the part of weight $n$, we therefore obtain:

$$s_n(b_1, \ldots, b_n) = \beta_1^n + \cdots + \beta_n^n.$$

The expression $\beta_1^n + \cdots + \beta_n^n$ is symmetric in the $\beta_i$, and can therefore be written as a polynomial in the $b_j$.

Examples:

$$s_0 = 1, \quad s_1 = b_1,$$

$$s_2 = b_1^2 - 2b_2, \quad s_3 = 3b_2 - 3b_2 b_1 + b_1^3.$$

Now we give a lemma, which for a fixed power series $Q$ displays all these values $s_n$ as coefficients in a fixed power series. As usual, we write $f(x) = x/Q(x)$.

**Lemma (Cauchy):** One has

$$x \frac{f'(x)}{f(x)} = \sum_{j=0}^{\infty} (-1)^j s_j \cdot x^j.$$

**Proof:**

$$f(x) = \frac{x}{(1 + \beta_1 x) \cdots (1 + \beta_n x)} \quad (x^{n+2})$$

$$\Rightarrow \frac{f'(x)}{f(x)} = \frac{1}{x} \frac{-\beta_1}{1 + \beta_1 x} \cdots \frac{-\beta_n}{1 + \beta_n x} \quad (x^n)$$

$$\Rightarrow x \frac{f'(x)}{f(x)} = 1 + \frac{-\beta_1 x}{1 - (-\beta_1 x)} + \cdots + \frac{-\beta_n x}{1 - (-\beta_n x)} \quad (x^{n+1})$$

$$= 1 + \sum_{j=1}^{\infty} \left( \sum_{j=1}^{\infty} (-\beta_j x)^j \right) \cdot (-\beta_1 x)^j \quad (x^{n+1}).$$
Example: $Q(x) = x/(1 - e^{-x})$, \( f(x) = 1 - e^{-x} \). With these power series, one defines the Bernoulli numbers \( B_j \) by

$$Q(-x) = \sum_{j=0}^{\infty} \frac{B_j}{j!} x^j.$$ 

Then

$$x \frac{f'(x)}{f(x)} = x \frac{e^{-x}}{1 - e^{-x}} = x \frac{1}{e^x - 1} = \frac{-x}{1 - e^x} = Q(-x),$$

so that

$$s_j = (-1)^j \frac{B_j}{j!}.$$ 

For the Todd polynomials \( T_n \), which one obtains as the multiplicative sequence for this power series \( Q \), the coefficients \( s_n \) of \( c_n \) are therefore the same as the coefficients \( b_n \) in the power series \( Q \). As one easily sees, these are also the coefficients of \( c_n^\cdot \).

Examples:

\[
\begin{align*}
T_1 &= \frac{c_1}{2}, & T_2 &= \frac{c_2 + c_1^2}{12}, \\
T_3 &= \frac{c_2 c_1}{24}, & T_4 &= \frac{-c_4 + 3c_3 c_1 + 3c_2^2 + 4c_2c_1^2 - c_1^4}{720}.
\end{align*}
\]

If \( X \) is a manifold for which all Chern classes apart from the highest vanish, then its genus is given by

$$\varphi(X) = s_n \cdot c_n[X].$$

Later we shall encounter genera for which the power series \( x \frac{f'(x)}{f(x)} \) has Eisenstein series as coefficients; the genus of such a manifold \( X \) would then be a multiple of the corresponding Eisenstein series.

One can also read off the \( s_n \) from the logarithm of the power series \( Q \):

\[
\begin{align*}
f(x) &= \exp(\ln(f(x))) = \exp\left( \int \frac{f'(x)}{f(x)} \, dx \right) \\
&= \exp\left( \int \left( \frac{1}{x} \sum_{j=0}^{\infty} (-1)^j s_j \cdot x^j \right) \, dx \right) \\
&= \exp\left( \ln(x) + \sum_{j=1}^{\infty} (-1)^j \frac{s_j}{j} x^j \right) \\
&= x \cdot \exp\left( \sum_{j=1}^{\infty} (-1)^j \frac{s_j}{j} x^j \right) \Rightarrow Q(x) = \exp\left( \sum_{j=1}^{\infty} (-1)^{j+1} \frac{s_j}{j} x^j \right).
\end{align*}
\]
The $s_n$ are therefore, up to the factor $(-1)^{n+1} \cdot \frac{1}{n}$, exactly the coefficients of the formal power series $\ln(Q(x))$. 
2 Elliptic genera

2.1 The Weierstrass \( \wp \)-function

Let \( \omega_1, \omega_2 \in \mathbb{C} \) such that \( \tau := \omega_2/\omega_1 \not\in \mathbb{R} \cup \{\infty\} \); we can number \( \omega_1 \) and \( \omega_2 \) such that \( \text{Im} (\tau) > 0 \). Then \( L = \mathbb{Z} \cdot \omega_2 + \mathbb{Z} \cdot \omega_1 \) is a lattice in \( \mathbb{C} \); put \( L' = L \setminus \{0\} \). For \( z \in \mathbb{C} \),

\[
\wp (z) := \frac{1}{z^2} + \sum_{\omega \in L'} \left( \frac{1}{(z - \omega)^2} - \frac{1}{\omega^2} \right)
\]

defines a meromorphic function with poles of order two at all lattice points. This function is called the Weierstrass \( \wp \)-function.

**Definition:** A meromorphic function \( f : \mathbb{C} \to \mathbb{C} \cup \{\infty\} \) is called elliptic (doubly periodic) with respect to a lattice \( L \subset \mathbb{C} \) if \( f(z + \omega) = f(z) \) for all \( \omega \in L \).

An elliptic function is therefore the same as a meromorphic function on the elliptic curve \( E = \mathbb{C}/L \) which is isomorphic to a torus.

**Examples:** The \( \wp \)-function is an even function. Since

\[
\wp' (z) = \sum_{\omega \in L} \frac{-2}{(z - \omega)^3}
\]
is an odd elliptic function, one has \( \wp(z + \omega_i) - \wp(z) \equiv c_i \); putting \( z = -(\omega_i/2) \) shows that \( c_i = 0 \). Therefore the \( \wp \)-function is elliptic. Moreover, \( \wp \) satisfies the following differential equation:

\[
\wp'(z)^2 = 4 \cdot \wp(z)^3 - g_2 \cdot \wp(z) - g_3,
\]

where \( g_2 \) and \( g_3 \) depend on the lattice.

With the definition \( s_r (L) := \sum_{\omega \in L'} \frac{1}{\omega^r} \) we obtain series which are absolutely convergent for \( r > 2 \); we have \( s_r (L) = 0 \) for odd \( r \) (since for \( \omega \in L \) also \( -\omega \in L \)). Moreover:

\[
g_2(L) = 60 \cdot s_4(L), \quad g_3(L) = 140 \cdot s_6(L).
\]

For elliptic functions there are theorems of Liouville-type (cf. [La73]):

**Theorem:** For \( f(z) \) elliptic with respect to \( L \), the following hold on \( \mathbb{C}/L \):

1) The number of zeroes of \( f \) is equal to the number of poles (counted with multiplicities!).
2) The sum of the residues is zero.
3) Let \( (f) = \sum_{a \in \mathbb{C}/L} n_a \cdot (a) \) with \( n_a \in \mathbb{Z} \) be the divisor of \( f \); then \( \sum_{a \in \mathbb{C}/L} n_a \cdot a \equiv 0 \) modulo \( L \), i.e. \( \sum_{a \in \mathbb{C}/L} n_a \cdot a \in L \).
Corollary: There is no elliptic function which has precisely one pole of order one.

The elliptic function \( \wp' \) has a pole of order three in \( \mathbb{C}/L \) and therefore also three zeroes. Since \( \wp' \) is odd, it follows from \( \wp'(-z) = -\wp'(z) \) that for those \( z \) with \( -z \equiv z \mod L \), either \( \wp'(z) = 0 \) or \( \wp \) has a pole at \( z \). However, \( -z \equiv z \mod 2 \cdot z \in L \), and on the torus \( \mathbb{C}/L \cong S^1 \times S^1 \) there are exactly three non-trivial two-division points; namely, for the chosen basis \( \omega_1, \omega_2 \) of the lattice \( L \) these are the points \( \omega_1/2, \omega_2/2 \) and \( (\omega_1 + \omega_2)/2 \). At these points the \( \wp \)-function has no pole, so the function \( \wp' \) vanishes there.

A standard notation is now:

\[
e_1 := \wp\left(\frac{\omega_1}{2}\right), \quad e_2 := \wp\left(\frac{\omega_2}{2}\right), \quad e_3 := \wp\left(\frac{\omega_1 + \omega_2}{2}\right).
\]

In terms of \( e_1, e_2 \) and \( e_3 \) the differential equation for \( \wp \) can now also be written as

\[
\wp'(z)^2 = 4\wp(z)^3 - g_2 \cdot \wp(z) - g_3 \\
= 4(\wp(z) - e_1)(\wp(z) - e_2)(\wp(z) - e_3).
\]

One therefore has:

\[
e_1 + e_2 + e_3 = 0, \\
4(e_1e_2 + e_1e_3 + e_2e_3) = -g_2, \\
4e_1e_2e_3 = g_3.
\]

The \( \wp \)-function takes each value exactly twice; since it is an even function, four times the two preimages coincide, namely exactly for the two-division points. For the other values the two preimages are distinguished by the sign of \( \wp'(z) \). One therefore obtains by means of \( \wp \) a double covering of \( P_1(\mathbb{C}) \) by the torus \( \mathbb{C}/L \), which is branched at the two-division points. The cubic curve in \( \mathbb{C}^2 \subset P_3(\mathbb{C}) \) given by the equation \( y^2 = 4x^3 - g_2x - g_3 \) is smooth and has exactly one point on the line at infinity in \( P_2(\mathbb{C}) \). On the basis of the differential equation for \( \wp \), it is parametrized by \( x = \wp(z), y = \wp'(z) \), where the point \( 0 \in \mathbb{C}/L \) is mapped to the point of the curve lying at infinity (inflection point). By means of this isomorphism the cubic curve obtains a group structure:
Proposition: Three points \( P_1, P_2 \) and \( P_3 \) on the curve lie on a line, if and only if \( P_1 + P_2 + P_3 = 0 \).

Proof: The linear equation \( a \cdot x + b \cdot y + c = 0 \) restricted to the curve yields, in view of the parametrization by \( \varphi \) and \( \varphi' \), the equation

\[
h(z) := a \cdot \varphi(z) + b \cdot \varphi'(z) + c = 0.
\]

Now \( h \) is an elliptic function, i.e. a meromorphic function on \( \mathbb{C}/\mathbb{L} \) with a pole of order three at \( 0 \in \mathbb{C}/\mathbb{L} \), hence it has also exactly three zeroes \( z_1, z_2, z_3 \). For these there holds according to Liouville:

\[
z_1 + z_2 + z_3 - 3 \cdot 0 = 0 \in \mathbb{C}/\mathbb{L}.
\]

Because we require that the \( \varphi \)-function be a group isomorphism of \( \mathbb{C}/\mathbb{L} \) onto the cubic curve, the sum of the three intersection points of the curve with the line must likewise be zero.

Remark: By explicitly calculating the intersection points of the cubic with the line, one obtains the addition theorem for the \( \varphi \)-function.

2.2 Construction of elliptic genera

The \( \varphi \)-function is an even function and takes the values \( e_1, e_2 \) and \( e_3 \) with order two, i.e. \( \varphi(z) - e_1 \) has a double zero at \( \omega_1/2 \). Therefore we can take the square root, and
f(z) := \frac{1}{\sqrt{\wp(z) - e_1}} with the choice of sign \sqrt{\wp(z) - e_1} = \frac{1}{2} + \cdots is defined and single-valued on \mathbb{C}. The odd function f is meromorphic on \mathbb{C}, with zeroes of order 1 at all lattice points and poles of order 1 at (\omega_3/2) + L. Although f is not elliptic with respect to L, there exists a sublattice \tilde{L} of index 2 in L with respect to which f is elliptic. The projection \mathbb{C}/L \to \mathbb{C}/L is an unbranched double covering. The divisor of f is

\[(f) = 0 + \alpha - (\omega_1/2) - (\omega_1/2 + \alpha).\]

Because \((f) \in \tilde{L}\) (cf. part 3 of the theorem in section 2.1), we have \(\omega_1 \in \tilde{L}\); therefore \(\tilde{L} = \mathbb{Z} \cdot 2\omega_2 + \mathbb{Z} \cdot \omega_1\) and \(f(z + \omega_2) = -f(z)\).

**Theorem:** The genus defined by the function \(f(z) = \frac{1}{\sqrt{\wp(z) - e_1}}\) is an elliptic genus as defined in section 1.7, i.e. for the derivative \(g'\) of the inverse function and the duplication formula hold:

\[g'(y) = 1 + \delta \cdot y^2 + \cdots \quad \text{and} \quad f(2x) = \frac{2f(x)f'(x)}{1 - \varepsilon \cdot f(x)^4}.\]

Further, f satisfies the differential equation

\[f'(x)^2 = 1 - 2\delta \cdot f(x)^2 + \varepsilon \cdot f(x)^4,\]

and has the addition theorem

\[f(u + v) = \frac{f(u)f'(v) + f'(u)f(v)}{1 - \varepsilon \cdot f(u)^2 f(v)^2}.\]

Here \(\delta = -\frac{3}{2} \cdot e_1\), and \(\varepsilon = (e_1 - e_2)(e_1 - e_3)\).

**Remark:** Since the \(\wp\)-function assumes each value twice, counted with multiplicity, the \(e_j\) as values at the two-division points are distinct, and therefore \(\varepsilon = (e_1 - e_2)(e_1 - e_3) \neq 0\) and \(\delta^2 - \varepsilon = \frac{3}{4}(e_2 - e_3)^2 \neq 0\). So we cannot obtain the \(A\) and \(L\)-genus in this way, because there we have \(\varepsilon = 0\) resp. \(\delta^2 - \varepsilon = 0\).

**Proof of the theorem:** We consider the curve in \(P_2(\mathbb{C})\) which is parametrized by \(\xi = f(z)\) and \(\eta = f'(z)\). With \(x = \wp(z)\) and \(y = \wp'(z)\) one has:

\[\xi = \frac{1}{\sqrt{\wp(z) - e_1}} = \frac{1}{\sqrt{x - e_1}} \Rightarrow x = \xi^{-2} + e_1,\]

\[\eta = f'(z) = ((\wp(z) - e_1)^{-1/2})' = -\frac{\wp'(z)}{2} \cdot (\wp(z) - e_1)^{-3/2} = -\frac{y}{2} \cdot (x - e_1)^{-3/2} = -\frac{y}{2} \cdot \xi^3 \Rightarrow y = -2\eta\xi^{-3}.\]
2.2 Construction of elliptic genera

The \((\xi, \eta)\)-curve satisfies the following equation:

\[
y^2 = 4(x - e_1)(x - e_2)(x - e_3) = 4x^3 - g_2x - g_3
\]

\[
\Rightarrow 4\eta^2\xi^{-6} = 4\xi^{-2}(\xi^{-2} + e_1 - e_2)(\xi^{-2} + e_1 - e_2)
\]

\[
\Rightarrow \eta^2 = (1 + \xi^2(e_1 - e_2))(1 + \xi^2(e_1 - e_3))
\]

\[
= 1 + (3e_1 - e_1 - e_2)(3e_1 - e_1 - e_3)(e_1 - e_2)(e_1 - e_3)(\xi^4)
\]

\[
= 1 + 3e_1 \xi^2 + (e_1 - e_2)(e_1 - e_3)(\xi^4)
\]

\[
= 1 - 2\delta \cdot \xi^2 + \varepsilon \cdot \xi^4,
\]

with \(\delta = -\frac{1}{2} \cdot e_1\) and \(\varepsilon = (e_1 - e_2)(e_1 - e_3)\). Therefore \(f(z) = (g(z) - e_1)^{-1/2}\) indeed satisfies the differential equation

\[
f'(z)^2 = 1 - 2\delta \cdot f(z)^2 + \varepsilon \cdot f(z)^4
\]

for the given values of \(\delta\) and \(\varepsilon\). The \((\xi, \eta)\)-curve is obtained from the elliptic curve \(C/\mathcal{L}\) by the identification of \((\omega_1/2)\) with \((\omega_1/2) + \omega_2\). From this there arises a singularity of type \(A_3\) at infinity. The formulas for \(x\) and \(y\) yield a covering of degree two of the \((x,y)\)-curve by the \((\xi, \eta)\)-curve.

Singularity of type \(A_3\)

The derivation of the addition theorem for \(f\) was already carried out by Fagnano in 1718 for duplication in connection with an investigation on the lemniscate, and was given in general by Euler (cf. [Eu251]): put

\[
R(u,v) := \frac{f(u)f'(v) + f'(u)f(v)}{1 - \varepsilon \cdot f(u)^2f(v)^2}
\]

and consider the total differential

\[
dR(u,v) = \frac{\partial R}{\partial u} du + \frac{\partial R}{\partial v} dv.
\]

We have

\[
\left( \star \right) \quad \frac{\partial R}{\partial u} \cdot \left( 1 - \varepsilon f(u)^2f(v)^2 \right)^2 = \left( f'(u)f'(v) + f''(u)f(v) \right) \cdot \left( 1 - \varepsilon f(u)^2f(v)^2 \right)
\]

\[
- \left( f(u)f'(v) + f'(u)f(v) \right) \cdot \left( -2\varepsilon f(u)^2f'(v) \right).
\]
Now we calculate \( f'' \) from

\[
f'(u)^2 = 1 - 2\delta f(u)^2 + \varepsilon f(u)^4
\]

\[
\Rightarrow 2f'(u)f''(u) = -4\delta f(u)f'(u) + 4\varepsilon f(u)^3 f'(u)
\]

\[
\Rightarrow f''(u) = -2\delta f(u) + 2\varepsilon f(u)^3.
\]

We now substitute this into \((\star)\) and then calculate the non-symmetric component in \( u \) and \( v \) (\( S \) denotes the additive subgroup of symmetric functions in \( u \) and \( v \)):

\[
\frac{\partial R}{\partial u} \cdot (1 - \varepsilon f(u)^2 f(v)^2)^2 \equiv 2\varepsilon f(u)^3 f(v) \cdot (1 - \varepsilon f(u)^2 f(v)^2)
\]

\[
+ 2\varepsilon f(u)f(v)^3 f'(u)^2 \tag{S}
\]

\[
\equiv 2\varepsilon f(u)^3 f(v) - 2\varepsilon^2 f(u)^5 f(v)^3
\]

\[
+ 2\varepsilon f(u)f(v)^3 f'(u)^2 \tag{S}
\]

\[
\equiv 2\varepsilon f(u)^3 f(v) - 2\varepsilon^2 f(u)^5 f(v)^3
\]

\[
+ 2\varepsilon f(u)f(v)^3 \cdot (1 - 2\delta f(u)^2 + \varepsilon f(u)^4) \tag{S}
\]

\[
\equiv 0 \tag{S}
\]

Therefore \( \frac{\partial R}{\partial u} = s(u, v) \) for some symmetric functions in \( u \) and \( v \), hence so is \( \frac{\partial R}{\partial u} = s(v, u) = s(u, v) \), and \( dR(u, v) = s(u, v) \cdot (du + dv) = s(u, v) \cdot d(u + v) \).

For \( u + v = c \) constant it now follows from \( dR(u, v) = 0 \) that \( R(u, v) = \tilde{c} \) is constant, with \( \tilde{c} = R(0, c) = f(c) = f(u + v) \). This proves the addition formula and gives the duplication formula as a special case:

\[
f(2x) = \frac{2f(x)f'(x)}{1 - \varepsilon \cdot f(x)^4}.
\]

Remark: If one lets the lattice degenerate by \( \omega_1 \to 0 \), then one obtains with \( \varepsilon = 0 \) the case \( \varepsilon = \delta^2 \). Through this limit process, the function \( f \) for the degenerate lattice must satisfy the differential equation \( f' = 1 - \delta \cdot f^2 \), hence can be written in the form \( f(x) = \tanh(\alpha x)/\alpha \) where \( \alpha \) is determined by \( \delta \). For \( \delta = 1 \) (hence \( \alpha = 1 \)) we obtain the \( L \)-genus.

In the other two degenerate cases \( \omega_1 \to \omega_2 \ (e_1 = e_2) \), resp. \( \omega_2 \to 0 \ (e_1 = e_3) \) one has \( \varepsilon = 0 \). The differential equation becomes \( f'^2 = 1 - 2\delta \cdot f^2 \) and has the solutions \( f(x) = \sinh(\alpha x)/\alpha \). In particular, for \( \delta = -\frac{1}{8} \ (\alpha = \frac{3}{2}) \) one obtains the \( A \)-genus.

The above construction yields for each lattice \( L \subset \mathbb{C} \) an elliptic genus, where \( \delta \) and \( \varepsilon \) depend on \( L \). On the other hand, if \( \delta \) and \( \varepsilon \) are given then \( e_1, e_2 \) and \( e_3 \) can be determined (notice that \( e_1 + e_2 + e_3 = 0 \)). The discriminant of the equation \( y^2 = 4(x - e_1)(x - e_2)(x - e_3) \) is

\[
\Delta = 64\varepsilon^2(\delta^2 - \varepsilon).
\]
If $\Delta$ is different from zero, then the equation determines an elliptic curve $\mathbb{C}/L$, where $L \subset \mathbb{C}$ is a lattice, which yields the elliptic genus corresponding to $\delta$ and $\varepsilon$ by means of the above construction. If the discriminant $\Delta$ vanishes, then either $\varepsilon = 0$ or $\varepsilon = \delta^2$ and the corresponding elliptic genus arises by degeneration of the lattice $L$.

In view of the differential equation which is satisfied by the power series $f$ for elliptic genera, it is clear that the coefficient of $x^{2k}$ in $Q(x) = x/f(x)$ is a homogeneous polynomial of weight $2k$ in $\delta$ and $\varepsilon$, to which we assign the weights 2 resp. 4. Hence the elliptic genus of a compact, oriented, differentiable manifold $M^{4k}$ is a homogeneous polynomial of weight $2k$ in $\delta$ and $\varepsilon$. Moreover, $\delta$ and $\varepsilon$ are lattice invariants of weights 2 and 4, i.e. for each lattice $L \subset \mathbb{C}$ and $\lambda \in \mathbb{C}$, $\lambda \neq 0$, we have $\delta(\lambda \cdot L) = \lambda^{-2} \cdot \delta(L)$, resp. $\varepsilon(\lambda \cdot L) = \lambda^{-4} \cdot \varepsilon(L)$. Hence the elliptic genus of a manifold $M^{4k}$ is a lattice invariant of weight $2k$. Further lattice invariants of weight $2k$ are the earlier defined $s_{2k} = \sum_{\omega \in L \setminus \frac{1}{2} \mathbb{Z}^2}$. The lattice invariants $\delta$ and $\varepsilon$ are, as we have seen, really lattice invariants for lattices with distinguished two-division points. For the precise connection between elliptic genera and modular forms on the congruence subgroup $\Gamma_0(2)$ of $\text{SL}_2(\mathbb{Z})$ we refer to Appendix I.

As was mentioned earlier, an elliptic genus is already determined by its values on $P_2(\mathbb{C})$ and $P_k(\mathbb{H})$. Indeed, we have (cf. section 1.7):

\[
\varphi(P_2(\mathbb{C})) = \delta,
\]

\[
\varphi(P_k(\mathbb{H})) = \begin{cases} 
 e^{k/2}, & k \equiv 0 \ (2), \\
 0, & k \equiv 1 \ (2).
\end{cases}
\]

### 2.3 An excursion on the lemniscate

The lemniscate is the geometric locus of all points of the Euclidean plane, for which the product of the distances to the foci $(a, 0)$ and $(-a, 0)$ is equal to $a^2$. 

![The lemniscate](image)
We have therefore the defining equation

\[((x - a)^2 + y^2) \cdot ((x + a)^2 + y^2) = a^4.\]

We introduce the new coordinate \( r^2 = x^2 + y^2 \) and obtain

\[(r^2 - 2ax + a^2) \cdot (r^2 + 2ax + a^2) = a^4\]
\[\Rightarrow (r^2 + a^2)^2 - 4a^2x^2 = a^4\]
\[\Rightarrow r^4 + 2a^2r^2 - 4a^2x^2 = 0.\]

Without restriction, normalize \( a \) so that \( 2a^2 = 1.\)

\[\Rightarrow r^4 + r^2 - 2x^2 = 0\]
\[\Rightarrow r^4 + r^2 - 2(r^2 - y^2) = 0 \quad \text{(since} \ x^2 + y^2 = r^2)\]
\[\Rightarrow r^4 - r^2 + 2y^2 = 0.\]

Hence:

\[2x^2 = r^2 + r^4 \quad \text{and} \quad 2y^2 = r^2 - r^4.\]

This yields a parametrization of the lemniscate by the parameter \( r.\) In the following, \( \dot{x} \) and \( \dot{y} \) denote differentiation with respect to \( r.\)

For the arc length of the lemniscate we now obtain

\[2x\dot{x} = r + 2r^3 \quad \text{and} \quad 2y\dot{y} = r - 2r^3\]
\[\Rightarrow \dot{x}^2 = \frac{(r + 2r^3)^2}{4x^2} = \frac{r^2(1 + 2r^2)^2}{2(r^2 + r^4)} = \frac{(1 + 2r^2)^2}{2(1 + r^2)} .\]

Analogously:

\[\dot{y}^2 = \frac{(1 - 2r^3)^2}{2(1 - r^2)}.\]

Hence we obtain

\[\dot{x}^2 + \dot{y}^2 = \frac{(1 + 2r^2)^2(1 - r^2) + (1 - 2r^3)^2(1 + r^2)}{2(1 - r^4)} = \frac{1}{1 - r^4},\]

and therefore

\[\text{arc length} = \int_0^r \sqrt{\dot{x}^2 + \dot{y}^2} \, dt = \int_0^r \frac{dt}{\sqrt{1 - t^4}} .\]
For the elliptic genus we have obtained

\[ g(y) = \int_0^y \frac{dt}{f'(g(t))} = \int_0^y \frac{dt}{\sqrt{1 - 2\delta f(g(t))^2 + \varepsilon f(g(t))^4}} = \int_0^y \frac{dt}{\sqrt{1 - 2\delta \cdot t^2 + \varepsilon \cdot t^4}}. \]

The arc length of the lemniscate therefore corresponds to the logarithm of an elliptic genus for the special case \( \delta = 0 \) and \( \varepsilon = -1 \).

A classical problem, which as was mentioned above was already treated by Fagnano in the year 1718, concerns the duplication of the arc: For a given parameter \( r \), find the parameter \( R \) corresponding to the doubled arc length.

Put

\[ P(t) := 1 - 2\delta \cdot t^2 + \varepsilon \cdot t^4 \quad \text{and} \quad x_i := g(y_i) = \int_0^{y_i} \frac{dt}{\sqrt{P(t)}} \]

for \( i = 1, 2 \) and \( y_i \in \mathbb{C} \).

As we have previously seen, with \( y_i = f(x_i) \) we have

\[ x_1 + x_2 = g(y_1) + g(y_2) = g(f(x_1 + x_2)) = g \left( \frac{f(x_1)f'(x_2) + f'(x_1)f(x_2)}{1 - \varepsilon f(x_1)^2 f(x_2)^2} \right) = g \left( \frac{y_1 \sqrt{P(y_2)} + y_2 \sqrt{P(y_1)}}{1 - \varepsilon y_1^2 y_2^2} \right) = g(y_1 + y_2 + \cdots). \]

For the lemniscate this means:

\[ R = \frac{2r \cdot \sqrt{1 - r^4}}{1 + r^4} = 2r + \cdots. \]

For Fagnano, it was an interesting question whether the parameter \( R \) could be constructed from \( r \) by means of circles and lines (i.e. "ruler and compass"). The formula above uses only addition, square root and product; therefore \( R \) is indeed geometrically constructible.
2.4 Geometric complement on the addition theorem

As we have seen, the elliptic functions \( I \) and \( f \) associated to a lattice \( \tilde{L} \) parametrize a curve in \( P_2(\mathbb{C}) \) which is given by \( y^2 = 1 - 2\delta \cdot x^2 + \varepsilon \cdot x^4 \). The group law on the elliptic curve \( \mathbb{C}/\tilde{L} \) thereby corresponds to the addition theorem for the elliptic genus. J. Nekovář has pointed out a beautiful geometric proof of the group law in [Ma79].

We therefore consider the curve \( C \) with equation \( y^2 z^2 = z^4 - 2\delta \cdot x^2 z^2 + \varepsilon \cdot x^4 \) in homogeneous coordinates. It has a unique singular point, namely \( P = (0 : 1 : 0) \); and the line \( \{z = 0\} \) is doubly tangent at \( P \), touching the curve there to order four. Under the parametrization of the curve by \( I \) and \( I' \), the points \((w_1, t_1)\) and \((w_2, t_2)\) in \( \mathbb{C}/\tilde{L} \) are both mapped to \( P \). Away from the singularity, the map is one-to-one. The neutral element \( 0 \) of the group \( \mathbb{C}/\tilde{L} \) is mapped to the point \( Q = (0 : 1 : 1) \).

Now let \( yz = z^2 + A \cdot xz + B \cdot x^2 \) be a family of parabolas. To any two points on \( C \) there is a parabola in the family which goes through both. This cuts our curve in 8 points; among these, 4 intersection points lie in the affine part (including \( Q \)) while the point \( P \) is always an intersection point of order four. Let \((x_1, y_1), (x_2, y_2)\) and \((x_3, y_3)\) be the three intersection points in the affine part different from the neutral element.

The meromorphic function \( h := (yz - z^2 - A xz - B x^2)/z^2 \) on the curve has as divisor

\[
(h) = (0:1:1) + (x_1:y_1:1) + (x_2:y_2:1) + (x_3:y_3:1) + 4 \cdot P - 8 \cdot P.
\]

If we pull \( h \) back to the elliptic curve by means of the parametrization \((x:y:z) = (f(t):f'(t):1)\), then the divisor there is:

\[
(\tilde{h}) = (0) + (t_1) + (t_2) + (t_3) - 2 \cdot (\omega_1/2) - 2 \cdot (\omega_1/2 + \omega_2) \equiv 0 \quad (\tilde{L})
\]

\[
\Rightarrow \quad t_1 + t_2 + t_3 \equiv 0 \quad (\tilde{L})
\]

\[
\Rightarrow \quad -t_3 \equiv t_1 + t_2 \quad (\tilde{L})
\]

\[
\Rightarrow \quad -x_3 = -f(t_3) = f(-t_3) = f(t_1 + t_2).
\]

We have to express \(-x_3 = f(t_1 + t_2)\) in terms of \( x_1 = f(t_1) \) and \( x_2 = f(t_2) \), to derive the addition theorem for \( f \).

To do this, substitute the equation of the parabolas into the equation of the curve (now affine again):

\[
(B^2 - \varepsilon) \cdot x^4 + 2AB \cdot x^3 + (A^2 + 2B + 2\delta) \cdot x^2 + 2A \cdot x = 0
\]

\[
\Rightarrow \quad (B^2 - \varepsilon) \cdot x^3 + 2AB \cdot x^2 + (A^2 + 2B + 2\delta) \cdot x + 2A = 0
\]

\[
\Rightarrow \quad x_1 + x_2 + x_3 = \frac{2AB}{\varepsilon - B^2} \quad \text{and} \quad x_1 x_2 x_3 = \frac{2A}{\varepsilon - B^2}
\]

\[
\Rightarrow \quad x_1 + x_2 + x_3 = B \cdot x_1 x_2 x_3 \quad \text{so} \quad x_3 = \frac{x_1 + x_2}{B \cdot x_1 x_2 - 1},
\]
2.4 Geometric complement on the addition theorem

since \( x_1, x_2, x_3 \) are precisely the roots of the polynomial.

\[
y_1 = 1 + A \cdot x_1 + B \cdot x_1^2, \quad y_2 = 1 + A \cdot x_2 + B \cdot x_2^2
\]
\[
\Rightarrow x_1 y_2 - x_2 y_1 = (x_1 - x_2)(1 - B \cdot x_1 x_2) \tag{I}
\]
\[
y_1^2 = 1 - 2A \cdot x_1 + A \cdot x_1^2, \quad y_2^2 = 1 - 2A \cdot x_2 + A \cdot x_2^2
\]
\[
\Rightarrow x_1 y_2^2 - x_2 y_1^2 = (x_1^2 - x_2^2)(1 - A \cdot x_1 x_2) \tag{II}
\]

(I) & (II) \quad \Rightarrow \quad x_1 y_2 + x_2 y_1 = \frac{x_1^2 y_2^2 - x_2^2 y_1^2}{x_1 y_2 - x_2 y_1}
\]
\[
= (x_1 + x_2) \frac{1 - A \cdot x_1^2 x_2^2}{1 - B \cdot x_1 x_2}
\]
\[
= -x_3 \cdot (1 - A \cdot x_1^2 x_2^2)
\]
\[
\Rightarrow \quad -x_3 = \frac{x_1 y_2 + x_2 y_1}{1 - A \cdot x_1 x_2^2}.
\]

Together with the parametrization \( x_i = f(t_i), y_i = f'(t_i) \) we obtain

\[
-x_3 = f(t_1 + t_2) = \frac{f(t_1)f'(t_2) + f(t_2)f'(t_1)}{1 - \varepsilon f(t_1)^2 f(t_2)^2}.
\]
3 A universal addition theorem for genera

3.1 Virtual submanifolds

Let $M^{2n}$ be a compact, oriented, differentiable manifold and $U \subset M$ an oriented, differentiable submanifold of codimension two. Let $u \in H^2(M; \mathbb{Z})$ be the Poincaré-dual cohomology class of the fundamental cycle of $U$. Further, let $TU$ and $TM$ be the tangent bundles of $U$, resp. $M$, and let $NU$ be the normal bundle of $U$ in $M$. By choosing a Riemannian metric we get an isomorphism $TU \oplus NU \cong TM|_U$ and $NU$ gets the structure of an $O(2)$-bundle. Since $M$ and $U$ are oriented, the structure group of $NU$ can be further reduced to $SO(2) \cong U(1)$. The bundle $NU$ can therefore be considered as a complex line bundle which has the first Chern class $i^*(u)$ ($i : U \hookrightarrow M$ inclusion), i.e.:

$$c(NU) = 1 + c_1(NU) = 1 + i^*(u)$$

$$\Rightarrow p(NU) = 1 + i^*(u^2).$$

Using $TU \oplus NU = i^*(TM)$, we obtain

$$p(U) \cdot p(NU) = i^*p(M)$$

$$\Rightarrow p(U) \cdot i^*(1 + u^2) = i^*p(M)$$

$$\Rightarrow p(U) = i^*(p(M) \cdot (1 + u^2)^{-1})$$

$$= i^*((1 + p_1(M) + p_2(M) + \cdots) \cdot (1 - u^2 + u^4 - u^6 \pm \cdots)).$$

Example:

$$p_1(U) = i^*(p_1(M) - u^2),$$

$$p_2(U) = i^*(p_2(M) - p_1(M) \cdot u^2 + u^4).$$

From topology one knows that for $a \in H^*(M; \mathbb{Z})$ holds:

$$i^*(a)[U] = (a \cdot u)[M].$$

Therefore the Pontrjagin numbers of $U$ are obtained by evaluation of a homogeneous polynomial of degree $2n$ in $u$ and the $p_i(M)$ on the fundamental cycle of the manifold $M$. The equivalence class $[U]$ in the cobordism ring $\Omega \otimes \mathbb{Q}$ therefore depends, for given $M$, only on the cohomology class $u$.

According to Thom [Th54], in our situation each cohomology class of dimension 2 can be represented by means of Poincaré duality by a submanifold of codimension 2; therefore $u \in H^2(M; \mathbb{Z})$ is called a virtual submanifold. Let $u_1, \ldots, u_r \in H^2(M; \mathbb{Z})$ then
A universal addition theorem for genera

(u_1, \ldots, u_r) is called a virtual submanifold of codimension 2r. This is represented by a manifold in $\Omega^{2n-2r} \otimes \mathbb{Q}$, which one obtains as follows: Represent $u_1$ by a submanifold $U_1$ of $M$, represent the restriction of $u_2$ to $U_1$ by a submanifold $U_2$ of $U_1$, etc., obtaining further submanifolds $U_3, \ldots, U_r$. The manifold $U_r$ is then a submanifold of $M$ of codimension 2r, which represents $(u_1, \ldots, u_r)$. An alternative construction is the following: If $u_1, \ldots, u_r$ can be represented by submanifolds $U'_1, \ldots, U'_r$ of $M$, which are in general position (transversal to one another), then their intersection represents $(u_1, \ldots, u_r)$.

Example: For $M = P_n(\mathbb{C})$, the $u_1, \ldots, u_r$ are integral multiples $u_i = d_i \cdot g$ of the generator $g$ of $H^2(P_n(\mathbb{C}); \mathbb{Z}) \cong \mathbb{Z}$, and correspond exactly to the hypersurfaces of degree $d_i$. The virtual submanifolds $(u_1, \ldots, u_r)$ correspond to complete intersections.

Analogous to the above, one obtains:

$$p(U_r) = i^* (p(M) \cdot (1 + u_1^2)^{-1} \cdots (1 + u_r^2)^{-1})$$

$$= i^*(1 + \tilde{p}_1 + \tilde{p}_2 + \cdots).$$

The Pontrjagin numbers of $U_r$ are therefore again polynomials in $p_i(M)$ and the $u_j$ evaluated on $M$, since for $4 \cdot \sum_{j=1}^{k} i_j = 2n - 2r = \dim U_r$ we have:

$$\left( p_{i_1}(U_r) \cdots p_{i_k}(U_r) \right)[U_r] = i^* \left( \tilde{p}_{i_1}(U_r) \cdots \tilde{p}_{i_k}(U_r) \right)[U_r]$$

$$= \left( \tilde{p}_{i_1}(U_r) \cdots \tilde{p}_{i_k}(U_r) \cdot u_1 \cdots u_r \right)[M].$$

Now let $Q(x)$, as usual, be an even and $f(x), g(y)$ be odd power series with $f(x) = x/Q(x), f(x) = y, g(y) = x$. Then the multiplicative sequence of polynomials $K_{n}(p_1, \ldots, p_n)$ associated to the power series $Q(x)$ was defined by

$$Q(x_1) \cdots Q(x_k) = \sum_{n=0}^{k} K_n(p_1, \ldots, p_n) + \sum_{n=k+1}^{\infty} K_n(p_1, \ldots, p_k, 0, \ldots, 0)$$

($p_i$ is the $i$-th elementary symmetric function in the $x^2_j$). Further, let $\varphi$ be the genus given by this multiplicative sequence, i.e.:

$$\varphi(M) := \left( \sum_{n=0}^{\infty} K_n(p_1, \ldots, p_n) \right)[M] = K(TM)[M].$$

In our situation this means:

$$\varphi(U_r) = i^* \left( K(TM) \cdot \frac{f(u_1) \cdots f(u_r)}{u_1 \cdots u_r} \right)[U_r]$$

$$= \left( K(TM) \cdot f(u_1) \cdots f(u_r) \right)[M].$$

Problem: Can the genus $\varphi$ of a submanifold represented by $u + v$ ($u, v \in H^2(M; \mathbb{Z})$) be calculated from the genera of the virtual submanifolds $\left( u_1, \ldots, u_s \right)$?
Since the power series $f(x)$ begins with $x$, the power series $f(u + v)$ can be formally expressed as a power series in $f(u)$ and $f(v)$. With $y_1 := f(u)$, $y_2 := f(v)$ we therefore have:

\[
    f(u + v) = f(g(f(u)) + g(f(v))) \\
    = f(g(y_1) + g(y_2)) \\
    = \sum_{r,s \geq 0} a_{rs} \cdot y_1^r y_2^s \\
    = F(y_1, y_2) = y_1 + y_2 + \cdots.
\]

Here $g$ is the inverse function of $f$. The power series $F$ is called the formal group law of $f$. From the definition of $F$ it follows that

\[
    g(F(y_1, y_1)) = g(y_1) + g(y_2).
\]

Therefore $g$ is also called the logarithm of the formal group law $F$. For an elliptic genus, we have already computed as an example (cf. section 2.2):

\[
    F(y_1, y_2) = \frac{y_1 \cdot \sqrt{P(y_2)} + y_2 \cdot \sqrt{P(y_1)}}{1 - \varepsilon \cdot y_1^2 y_2^2},
\]

where $P(y) = 1 - 2\delta \cdot y^2 + \varepsilon \cdot y^4$. Now let $u, v \in H^2(M)$ be given, then we have the following

**Lemma:** Let $a_{rs}$ be the coefficients of the formal group law $F$ of the power series $f$. Then

\[
    \varphi((u + v)) = \sum_{r,s \geq 0} a_{rs} \cdot \varphi\left(\underbrace{u, \ldots, u}_{r}, \underbrace{v, \ldots, v}_{s}\right).
\]

**Remark:** Note that the coefficients $a_{rs}$ are independent of $u, v$ and $M$.

**Proof of the lemma:**

\[
    \varphi((u + v)) = (K(TM) \cdot f(u + v))[M] \\
    = (K(TM) \cdot \sum_{r,s \geq 0} a_{rs} \cdot f(u)^r f(v)^s)[M] \\
    = \sum_{r,s \geq 0} a_{rs} \cdot \varphi\left(\underbrace{u, \ldots, u}_{r}, \underbrace{v, \ldots, v}_{s}\right).
\]

**Example:** For a 6-dimensional manifold $M^6$ this means

\[
    \varphi(u + v) = \varphi(u) + \varphi(v) - \delta \cdot \varphi(u, u, v) - \delta \cdot \varphi(v, v, u) \\
    = \varphi(u) + \varphi(v) - \delta \cdot (\varphi(u, u, v) + \varphi(v, v, u)) \\
    = \varphi(u) + \varphi(v) - \delta \cdot (u^2 [M] + v^2 [M]),
\]

where $\delta = \frac{1}{6}$. 

\[
    \varphi((u + v)) = \varphi(u) + \varphi(v) - \delta \cdot \varphi(u, u, v) - \delta \cdot \varphi(v, v, u) \\
    = \varphi(u) + \varphi(v) - \delta \cdot (\varphi(u, u, v) + \varphi(v, v, u)) \\
    = \varphi(u) + \varphi(v) - \delta \cdot (u^2 [M] + v^2 [M]),
\]
since the virtual submanifold of $M$ which corresponds to $(u, u, v)$, resp. $(v, v, u)$ has dimension zero (points).

Since $\Omega^4 \otimes \mathbb{Q}$ is only one-dimensional, there is (up to normalization by means of $\delta$) also only one genus here, namely for $\delta = 1$ the $L$-genus. Therefore

$$L(u + v) = L(u) + L(v) - u^2v[M] - v^2u[M].$$

### 3.2 A universal genus

The considerations about formal group laws can now be carried out for a universal genus (cf. [Oc87] and [Bu70]).

Take as genus the homomorphism $\varphi = \text{id}$ of the cobordism ring into itself. It is now interesting to ask about the characteristic power series and especially about the addition formula for this universal genus. We have

$$\varphi = \text{id} : \Omega \otimes \mathbb{Q} \to \Omega \otimes \mathbb{Q},$$

$$\varphi((u + v)) = \sum_{r,s} a_{rs} \cdot \varphi((u_r, \ldots, u_s, v_r, \ldots, v_s))$$

$$\Rightarrow (u + v) = \sum_{r,s} a_{rs} \cdot (u_r, \ldots, u_s, u_r, \ldots, v_s),$$

with cobordism classes $a_{rs} \in \Omega \otimes \mathbb{Q}$ of dimension $2(r + s - 1)$.

**Remark:** The above equation is an identity in the cobordism ring. Hence it is respected by all genera (ring homomorphisms). This means that one obtains the coefficients $a_{rs}$ in the addition theorem of an arbitrary genus $\varphi$ by $a_{rs} = \varphi(a_{rs})$. In this sense, the above formula yields a universal addition theorem (cf. [Qu69]).

The derivative of the logarithm $g$ belonging to $\varphi$ is, by our discussion in section 1.6,

$$g'(\varphi) = \sum_{n=0}^{\infty} P_n(C) \cdot y^n.$$

Milnor (cf. [Mi65]) has introduced some interesting manifolds, whose help the $a_{rs}$ can be determined.

In the following $\mathbb{P}_i$, resp. $\mathbb{P}_j$, shall always denote the complex projective space of (complex) dimension $i$, resp. $j$. We consider $\mathbb{P}_i \times \mathbb{P}_j$: The cohomology of the components is generated as rings by $u \in H^2(\mathbb{P}_i; \mathbb{Z})$ with $u^{i+1} = 0$ and $v \in H^2(\mathbb{P}_j; \mathbb{Z})$ with
\(v^{j+1} = 0\). We further identify \(u\), resp. \(v\), with the pulled-back classes under the projection onto the components, therefore \(u, v \in H^2(\mathbb{P}_i \times \mathbb{P}_j; \mathbb{Z})\) and \(H^*(\mathbb{P}_i \times \mathbb{P}_j; \mathbb{Z}) = \mathbb{Z}[u, v]/(u^{j+1}, v^{j+1})\). Let \(x = (x_0 : \ldots : x_i)\) and \(y = (y_0 : \ldots : y_j)\) be the homogeneous coordinates on \(\mathbb{P}_i\), resp. \(\mathbb{P}_j\). A polynomial \(P(x, y)\) has double degree \((a, b)\) if it is homogeneous in \(x\) of degree \(a\), and homogeneous in \(y\) of degree \(b\), so that \(P(\lambda \cdot x, \mu \cdot y) = \lambda^a \mu^b P(x, y)\). Then the equation \(P(x, y) = 0\) defines a hypersurface in \(\mathbb{P}_i \times \mathbb{P}_j\). This is smooth exactly if the partial derivatives of \(P\) with respect to the \(x_\alpha\) and \(y_\beta\) vanish only for \(x = y = 0\). Such a smooth hypersurface of double degree \((a, b)\) represents a cohomology class which depends only on \(a\) and \(b\), namely \(a \cdot u + b \cdot v\).

We consider the smooth hypersurface \(H_{ij} \subset \mathbb{P}_i \times \mathbb{P}_j\) of double degree \((1, 1)\), defined by \(x_0y_0 + \cdots + x_iky_k = 0\) \((k = \min\{i, j\})\). This has real dimension \(2(i + j - 1)\) and represents the cohomology class \(u + v\). We therefore obtain

\[
\varphi(H_{ij}) = H_{ij} = \sum_{r,s \geq 0} a_{r,s}(u, \ldots, u, v, \ldots, v)
\]

\[
= \sum_{r = 0}^{i} \sum_{s = 0}^{j} a_{r,s} \cdot \mathbb{P}_{i-r} \cdot \mathbb{P}_{j-s},
\]

since the virtual submanifolds \((u, \ldots, u)\) resp. \((v, \ldots, v)\) in \(\mathbb{P}_i\), resp. \(\mathbb{P}_j\) are represented by \(\mathbb{P}_{i-r} \subset \mathbb{P}_i\), resp. \(\mathbb{P}_{j-s} \subset \mathbb{P}_j\).

With the notations \(F(y_1, y_2) = \sum_{r,s \geq 0} a_{r,s} \cdot y_1^r y_2^s\) and \(H(y_1, y_2) = \sum_{i,j \geq 0} H_{ij} \cdot y_1^i y_2^j\) we have the following

**Proposition:** \(H(y_1, y_2) = F(y_1, y_2) \cdot g'(y_1) \cdot g'(y_2)\).

**Proof:**

\[
H(y_1, y_2) = \sum_{i,j \geq 0} H_{ij} \cdot y_1^i y_2^j
\]

\[
= \sum_{i,j \geq 0} \left( \sum_{r,s = 0}^i \sum_{r,s = 0}^j a_{r,s} \cdot \mathbb{P}_{i-r} \cdot \mathbb{P}_{j-s} \cdot y_1^r y_2^s \right)
\]

\[
= \sum_{r,s = 0}^i \left( a_{r,s} \cdot y_1^r y_2^s \cdot \sum_{i-r} \sum_{j-s} \mathbb{P}_{i-r} \cdot \mathbb{P}_{j-s} \cdot y_1^i \cdot y_2^j \right)
\]

\[
= \sum_{r,s = 0}^i \left( a_{r,s} \cdot y_1^r y_2^s \cdot \sum_{i-r} \sum_{j-s} \mathbb{P}_{i-r} \cdot \mathbb{P}_{j-s} \cdot y_1^i \cdot y_2^j \right)
\]

\[
= F(y_1, y_2) \cdot g'(y_1) \cdot g'(y_2).
\]

**Remark:** This is an identity in the cobordism ring. It holds also over \(\mathbb{Z}\). Since the power series \(g'(y)\) is invertible over \(\mathbb{Z}\), one can express the \(a_{r,s}\) in terms of the \(H_{ij}\) and the projective spaces. Thus one obtains concrete formulas, e.g.:

\[
H_{0,1} = a_{0,1} + \mathbb{P}_1,
\]

\[
H_{1,1} = a_{1,1} + 2a_{0,1} \cdot \mathbb{P}_1 + \mathbb{P}_1^2,
\]

\[
a_{0,1} = H_{0,1} - \mathbb{P}_1,
\]

\[
a_{1,1} = H_{1,1} - 2 \cdot H_{0,1} \cdot \mathbb{P}_1 + \mathbb{P}_1^2.
\]
Now let \( \varphi \) be an elliptic genus, so that with \( y = f(x) \) we have the formulas

\[
\begin{align*}
    f^2 &= P(y) = 1 - 2\delta \cdot y^2 + \epsilon \cdot y^4, \\
    g'(y) &= \frac{1}{\sqrt{P(y)}}, \\
    F(y_1, y_2) &= \frac{y_1 \cdot \sqrt{P(y_2)} + y_2 \cdot \sqrt{P(y_1)}}{1 - \epsilon \cdot y_1^2 y_2^2}.
\end{align*}
\]

From this we obtain the following Corollary:

\[
\sum_{i,j \geq 0} \varphi(H_{ij}) \cdot y_1^i y_2^j = \left( \frac{y_1}{\sqrt{P(y_1)}} + \frac{y_2}{\sqrt{P(y_2)}} \right) \cdot (1 + \epsilon y_1^2 y_2^2 + \epsilon^2 y_1^4 y_2^4 + \cdots).
\]

**Corollary:** Let \( j \geq i \) without restriction. Then

\[
\varphi(H_{ij}) = \begin{cases} 
0, & i \equiv 1 \mod 2, \\
\epsilon^{i/2} \cdot \varphi(P_{j-i-1}(C)), & i \equiv 0 \mod 2.
\end{cases}
\]

**Proof:** One can obtain the summand \( \varphi(H_{ij}) \cdot y_1^i y_2^j \) in the above equation for \( j \geq i \) only by multiplying \( y_2/\sqrt{P(y_2)} = y_2 \cdot g'(y_2) \) with \( (1 + \epsilon y_1^2 y_2^2 + \epsilon^2 y_1^4 y_2^4 + \cdots) \). The only term that yields the monomial \( y_1^i y_2^j \) for even \( i \) is \( a_{j-i} \cdot y_2^{-i} \cdot \epsilon^{i/2} y_1^i \), where \( a_k \) is the \( k \)-th coefficient of the power series

\[
\frac{y}{\sqrt{P(y)}} = y \cdot g'(y) = \sum_{k=1}^{\infty} \varphi(P_{k-1}) y^k.
\]

For odd \( i \) there is no monomial \( y_1^i y_2^j \).

**Remark:** Because \( H_{ij} = H_{ji} \), all cases are included. In particular, \( \varphi(H_{ij}) \) has the following values for special \( i \) and \( j \):

1) \( j \) even, \( j \geq i \): value 0,
2) \( |i - j| \) even: value 0,
3) \( i \) even, \( j = i + 1 \): value \( \epsilon^{i/2} \).

**Corollary:** \( \hat{A}(H_{ij}) = 0 \) for \( i, j > 0 \).

**Proof:** The \( \hat{A} \)-genus is the elliptic genus for \( \epsilon = 0 \) (with the normalization \( \delta = -\frac{1}{8} \)). So the vanishing on \( H_{ij} \) for \( i, j > 0 \) follows from the above corollary.
4 Multiplicativity in fibre bundles

4.1 The signature and the L-genus

The Milnor manifolds \( H_{ij} \subset \mathbb{P}_i \times \mathbb{P}_j \) of the last section are total spaces of a beautiful fibre bundle. To see this, we consider the projection of \( \mathbb{P}_i \times \mathbb{P}_j \) onto \( \mathbb{P}_i \). This induces for \( i \leq j \) a fibration of \( H_{ij} \) over \( \mathbb{P}_i \) with fibre \( \mathbb{P}_{j-i} \), as one sees directly from the equation for \( H_{ij} \). The manifold \( H_{ij} \) is therefore the total space of a projective bundle over \( \mathbb{P}_i \). Since for even \( j \) every genus \( \varphi(\mathbb{P}_{j-1}) \) is zero, and since in the last section we saw that for elliptic genera also \( \varphi(H_{ij}) = 0 \) for even \( j \) with \( j \geq i \), it follows that elliptic genera behave multiplicatively for these fibre bundles:

\[
\varphi(H_{ij}) = \varphi(\mathbb{P}_i) \cdot \varphi(\mathbb{P}_{j-1}) \quad \text{for } j \text{ even, } j \geq i.
\]

Remark: This multiplicativity does not hold for all \( i, j \). For \( j = i + 1 \) and \( i \) even one obtains \( \varphi(H_{ij}) = \varepsilon^{i/2} \) (cf. section 3.2), which can very well differ from \( \varphi(\mathbb{P}_i)^2 \). E.g., for \( i = 2 \) the condition for multiplicativity is

\[
\varepsilon = \varphi(H_{2,3}) = \varphi(\mathbb{P}_2)^2 = \delta^2,
\]

which characterizes up to normalization the \( L \)-genus.

We shall now consider more closely the \( L \)-genus in connection with multiplicativity. The \( L \)-genus is the elliptic genus with \( \varepsilon = \delta^2 = 1 \). It satisfies \( Q(x) = x \tanh (x) \) and \( f' = 1 - f^2 \). Since \( g'(y) = (1 - y^2)^{-1} \), the \( L \)-genus is characterized by \( L(\mathbb{P}_{2n}) = 1 \). Without normalization, it would give for \( \mathbb{P}_{2n} \) the value \( \delta^n \).

For a \( 4n \)-dimensional, oriented, compact manifold \( M \) there is in a natural way a quadratic form on \( H^{2n}(M; \mathbb{R}) \), given by \( a \mapsto (a \cdot a)[M] \). This can be diagonalized with respect to a suitable basis of \( H^{2n}(M; \mathbb{R}) \), say with \( p \) diagonal entries 1 and \( q \) diagonal entries \(-1\). Then \( p \) and \( q \) are uniquely determined. Due to Poincaré duality, this quadratic form is non-degenerate, hence \( p + q = \dim H^{2n}(M; \mathbb{R}) = b_{2n} \), the middle Betti number of the manifold. One defines the signature of \( M \) as the signature of the quadratic form, i.e. \( \text{sign}(M) := p - q \).

The \( L \)-genus yields precisely this important invariant of a manifold \( M^{4n} \):

**Signature Theorem (Hirzebruch):**

\[
L(M^{4n}) = \text{sign}(M^{4n}).
\]
Proof (cf. [Hi56]): The signature is a cobordism invariant, which is compatible with the ring structure (disjoint union and Cartesian product) in the cobordism ring $\Omega \otimes \mathbb{Q}$. Moreover, sign $(\mathbb{P}_{2n}) = 1$ and thus, since the $\mathbb{P}_{2n}$ from a basis sequence, sign $= L$.

Now in 1957 Chern, Hirzebruch and Serre proved the following result (cf. [ChHiSe57]):

**Theorem:** Let $E$ be the total space of a differentiable fibre bundle with fibre $F$ and base space $B$. Suppose that $E$, $B$, $F$ are connected, compact, oriented manifolds, and that the fundamental group $\pi_1(B)$ acts trivially on $H^*(F; \mathbb{R})$. Then the signature is multiplicative in this fibre bundle, i.e. sign $(E) = \text{sign}(B) \cdot \text{sign}(F)$.

**Remark:** For simply connected base spaces $B$ the theorem is naturally always applicable, since then $\pi_1(B) = 0$. Without the assumption on $\pi_1(B)$ the theorem is false (cf. section 4.6).

**Question:** Which genera are multiplicative under the above assumptions? (The Euler number is multiplicative in arbitrary fibre bundles, but is not a real cobordism invariant.)

**Theorem (Borel, Hirzebruch):** The signature is the only genus which is multiplicative in fibre bundles $(E, B, F)$ with simply connected $B$ and takes the value 1 on $\mathbb{P}_2(\mathbb{C})$.

**Proof:** As stated above, for $i \leq j$ the $\mathbb{P}_{ij}$ are total spaces of fibre bundles over $\mathbb{P}_i$ with fibre $\mathbb{P}_{j-1}$. For $i = 2$ and $j \neq 1$ odd, we have a sequence of 8, 12, 16, ...-dimensional manifolds, which are all fibered over $\mathbb{P}_2$. We show later in this section that $\mathbb{P}_2$ and the $\mathbb{H}_{2k+1}$ $(k = 1, 2, \ldots)$ form a basis sequence of the cobordism ring. Now let $\varphi$ be multiplicative as above. Since $\varphi(\mathbb{P}_2) = L(\mathbb{P}_2)$, the genus $\varphi$ coincides with $L$ on all manifolds of dimension 4 (these are generated in $\Omega \otimes \mathbb{Q}$ by $\mathbb{P}_2$). Then also $\varphi(\mathbb{H}_{2,3}) = L(\mathbb{H}_{2,3})$, since $\mathbb{H}_{2,3}$ is fibered over $\mathbb{P}_2$ with fibre $\mathbb{P}_2$ and $\varphi$ and $L$ are both multiplicative ($\mathbb{P}_2$ is simply connected). Now $\varphi$ and $L$ coincide on all manifolds up to dimension 8 (they are generated by $\mathbb{P}_2$ and $\mathbb{H}_{2,3}$). Since all $\mathbb{H}_{2k+1}$ fibre analogously into lower-dimensional projective spaces with base $\mathbb{P}_2$ (simply connected), one shows easily by induction that $\varphi$ and $L$ coincide on the entire cobordism ring. For the proof see also [BoHi59].

In order to show that the $\mathbb{H}_{2k+1}$ together with $\mathbb{P}_2$ form a basis sequence, we consider the number $s(M^{4k})$ which is defined as follows:

$$s(M^{4k}) := (x^{2k}_1 + \cdots + x^{2k}_k)[M^{4k}],$$

if $p(M) = (1 + x^2_1) \cdots (1 + x^2_k)$. The number $s$ is, on manifold of fixed dimension $4k$, the genus for $Q(x) = 1 + x^{2k}$. We shall also denote this genus by $s_k$.

**Lemma:** $s(\mathbb{P}_{2k}) = 2k + 1$.

**Proof:** We have

$$p(\mathbb{P}_{2k}) = (1 + g^2)^{2k+1} \Rightarrow s(\mathbb{P}_{2k}) = s_k(\mathbb{P}_{2k}) = (1 + g^{2k})^{2k+1}[\mathbb{P}_{2k}].$$
The coefficient of $g^{2k}$ in this expression is $2k + 1$ and

$$(2k + 1) \cdot g^{2k}[\mathbb{P}_{2k}] = 2k + 1.$$ 

Remark: For a product $M^{4k} = U \times V$ with $\dim U, \dim V < 4k$ we have $s(M) = 0$, since:

$$s(M) = s_k(M) = s_k(U) \cdot s_k(V) = 0.$$ 

Theorem (Thom): A sequence $M^4, M^8, \ldots$ of manifolds is a basis sequence (i.e. $\Omega \otimes Q = \mathbb{Q}[M^4, M^8, \ldots]$) if and only if $s(M^{4k})$ is different from zero for all $k$ (cf. [Th54]).

Proof: In $\Omega \otimes Q$ each manifold $M^{4k}$ is a polynomial in the projective spaces $\mathbb{P}_{2j}$, which are known to be a basis sequence. Evidently $\mathbb{P}_{2k}$ enters only linearly (with a coefficient $a_k$) in this polynomial. The $M^{4k}$ therefore form a basis sequence if and only if $a_k \neq 0$ for all $k$ (proof by induction). However, by the above remark,

$$s(M^{4k}) = s_k(M^{4k}) = a_k \cdot s_k(\mathbb{P}_{2k}) = a_k \cdot (2k + 1).$$

Proposition: If $i, j \geq 2$ with $\dim \mathbb{H}_{ij} = i + j - 1$ even, then

$$s(\mathbb{H}_{ij}) = -\binom{i+j}{i} \neq 0.$$ 

Proof: By construction of the $\mathbb{H}_{ij} \subset \mathbb{P}_i \times \mathbb{P}_j$, the results on virtual submanifolds yield:

$$p(\mathbb{H}_{ij}) = i^* \left( (1 + u^2)^{i+1} \cdot (1 + v^2)^{j+1} \cdot (1 + (u + v)^2)^{-1} \right)$$ 

$$\Rightarrow s(\mathbb{H}_{ij}) = s_{i+j-1/2}(\mathbb{H}_{ij})$$ 

$$= i^* \left( (1 + u^{i+j-1})^{i+1} \cdot (1 + v^{i+j-1})^{j+1} \cdot (1 + (u + v)^{i+j-1})^{-1} \right)[\mathbb{H}_{ij}].$$ 

Since for $j \geq 2$ (hence $i + j - 1 \geq i + 1$) it follows that $u^{i+j-1} = 0$ (analogously $i \geq 2$ implies $v^{i+j-1} = 0$), there only remains:

$$s(\mathbb{H}_{ij}) = i^* \left( (1 + (u + v)^{i+j-1})^{-1} \right)[\mathbb{H}_{ij}]$$ 

$$= i^* \left( 1 - (u + v)^{i+j-1} \right)[\mathbb{H}_{ij}]$$ 

$$= \left( (1 - (u + v)^{i+j-1}) \cdot (u + v) \right)[\mathbb{P}_i \times \mathbb{P}_j]$$ 

$$= -\binom{i+j}{i} \cdot (u^i v^j)[\mathbb{P}_i \times \mathbb{P}_j]$$ 

$$= -\binom{i+j}{i}.$$ 

Here we have twice dropped terms outside of the correct cohomology dimension in the calculation.

Corollary:

1) The manifolds $\mathbb{P}_2$ and $\mathbb{H}_{3,2k+1}$ for $k \geq 1$ form a basis sequence.

2) The manifolds $\mathbb{H}_{3,2k-2}$ for $k \geq 1$ form a basis sequence.
Proof: Since both sequences contain a manifold of dimension $4k$ for each $k$, it suffices to show that $s$ does not vanish on these manifolds. This is clear for $\mathbb{P}_3 \cong H_{3,0}$, and follows for $H_{3,2k+1}$ and $H_{3,2k-1}$ ($k > 1$) from the theorem.

One can even construct a basis sequence of the cobordism ring over $\mathbb{Z}$ (modulo torsion) from the complex projective spaces and the $H_{ij}$. This follows from (cf. [St68], p. 207)

**Theorem (Milnor): A sequence of manifolds $M^{4k}$ is a basis sequence over $\mathbb{Z}$ of $\Omega$ modulo torsion if it satisfies:**

$$s(M^{4k}) = \begin{cases} \pm p, & 2k + 1 = p^r, \text{p prime}, \\ \pm 1, & \text{otherwise}. \end{cases}$$

**Corollary:** A number $n \in \mathbb{Z}$ can be written as $s(M^{4k})$ if and only if $2k + 1$ is not a prime power, or $n \equiv 0 \pmod{p}$ for $2k + 1 = p^r$.

### 4.2 Algebraic preliminaries

Up to now, for a complex bundle $E$ over a manifold $X$ we have always factored the Chern classes $c_i(E)$ formally, i.e. $c(E) = \prod_{i=1}^{n} (1 + z_i)$. In the next section we will carry out the factorization geometrically (the splitting principle, cf. [Hi56] or [BoTu82]), and thereby locate these $z_i$ in the cohomology ring of a suitable manifold. We first give a few considerations of an algebraic nature.

We consider the polynomial ring $S = \mathbb{Z}[c_1, \ldots, c_n]$ in the indeterminates $c_i$ of weight $2i$. Later we shall substitute for the $c_i$ the Chern classes of a bundle, and so obtain a mapping of $S$ into the cohomology ring of the manifold $X$, where naturally relations can appear. Further, let $R = \mathbb{Z}[x_1, \ldots, x_n]$ be the polynomial ring in the indeterminates $x_i$ of weight 2. By means of $c_i \mapsto \sigma_i(x_1, \ldots, x_n)$ we obtain a degree preserving injection of $S$ into $R$ ($\sigma_i$ is the $i$-th elementary symmetric function). We identify the polynomial ring $S$ with its image in $R$. Hence $S$ becomes a subring of $R$, so that $R$ is a graded $S$-module. We want to determine a basis of this module.

We have:

$$(t + x_1) \cdots (t + x_n) = t^n + t^{n-1} \cdot c_1 + \cdots + c_n,$$

and for $t = -x_1$ we get

$$0 = x_1^n - x_1^{n-1} \cdot c_1 \pm \cdots + (-1)^n c_n.$$

Hence $\{1, x_1, \ldots, x_1^{n-1}\}$ is a basis of the $S$-module $S[x_1] \subset R$. The product $(t + x_2) \cdots (t + x_n)$ is a polynomial in $t$, whose coefficients are polynomials in the $c_j$ and $x_1$, for:

$$(t + x_2) \cdots (t + x_n) = t^{n-1} + t^{n-2} \cdot \sigma_{c_1} + \cdots + \sigma_{c_{n-1}},$$
where $c_i$ can be recursively determined by

$$c_k(x_1, \ldots, x_n) = c_k(x_2, \ldots, x_n) + x_1 c_{k-1}(x_2, \ldots, x_n) \quad \text{and} \quad c_0 := 1.$$ 

We therefore obtain inductively as basis elements of $R$ over $S$ all $n!$ monomials of the form $x_1^{i_1} \cdots x_n^{i_n}$ with $0 \leq i_j \leq n - j$ (in particular, always $i_n = 0$, since $x_n = c_1 - x_1 - \cdots - x_{n-1}$). Thus there is precisely one basis element of highest weight, namely $x_1^{n-1} \cdot x_2^{n-2} \cdots x_{n-1}$ with weight $n(n-1)$. Let $P \in R$; then $P$ can be written uniquely as an $S$-linear combination of the above basis elements. We are especially interested in the coefficient $\tilde{\rho}(P) \in S$ of the unique basis element of highest weight. We shall now determine this for the polynomial $P = \prod_{i>j} (x_i - x_j)$. Because $P$ and all the basis elements are homogeneous, this also holds for the coefficients $s_{i_1, \ldots, i_n}$ in the basis representation. Since $P$ has weight $n(n-1)$, the coefficient $s_{i_1, \ldots, i_n}$ has weight $n(n-1) - 2 \sum_{j=1}^n i_j$. Therefore the coefficient $\tilde{\rho}(P)$ has weight zero, hence $\tilde{\rho}(P) \in \mathbb{Z}$, while all other coefficients have strictly positive weight. Therefore we can determine $\tilde{\rho}(P)$ by computing $P$ modulo the ideal $I = (c_1, \ldots, c_n)$.

To do this, we consider the polynomial

$$(t + x_1) \cdots (t + x_n) = t^n + t^{n-1} \cdot c_1 + \cdots + c_n;$$

putting $t = 1 - x_1$ gives:

$$(1 + x_2 - x_1) \cdots (1 + x_n - x_1) = (1 - x_1)^n + (1 - x_1)^{n-1} \cdot c_1 + \cdots + c_n.$$

Since the ideal $I$ is homogeneous, we can consider the terms of equal weight modulo $I$ and obtain as components of highest weight of these expressions:

$$(x_2 - x_1) \cdots (x_n - x_1) \equiv n \cdot (-x_1)^{n-1} \quad (I).$$

By induction we obtain

$$\prod_{i>j} (x_i - x_j) \equiv n! \cdot (-x_1)^{n-1} (-x_2)^{n-2} \cdots (-x_{n-1}) \quad (I)$$

$$\equiv n! \cdot (-1)^{n(n-1)/2} x_1^{n-1} \cdots x_{n-1} \quad (I),$$

which gives

$$\tilde{\rho}\left(\prod_{i>j} (x_i - x_j)\right) = (-1)^{n(n-1)/2} \cdot n!.$$

For an arbitrary polynomial $P$ in $R$ we now put

$$\rho(P) := \tilde{\rho}(P) \cdot (-1)^{n(n-1)/2}.$$
With the notation \( \text{sgn}(s) \) for the sign of a permutation \( s \), we have the

**Proposition:** \( \rho(P) = \left( \sum_{s \in S_n} \text{sgn}(s) \cdot s(P) \right) / \prod_{i>j} (x_i - x_j) \).

**Proof:** Let \( Q \) be the numerator of the right side; then for each transposition \( \tau_{ij} \in S_n \) we have \( \tau_{ij}(Q) = -Q \). Polynomials with this property contain the factor \( x_i - x_j \). Therefore the quotient on the right side is a polynomial. In particular, it vanishes if the weight of \( P \) is smaller than \( n(n - 1) \). Since the quotient is also invariant under the action of \( S_n \), it is a polynomial in \( c_1 \) through \( c_n \). Moreover, the right side is \( S \)-linear. Since this is also true of the left side, it suffices to verify the equation on an \( S \)-basis of \( R \). For all our basis elements below weight \( n(n - 1) \) both sides give zero. In place of the basis element of highest weight we use the polynomial \( P = \prod_{i>j} (x_i - x_j) \), in whose basis representation the summand \( (-1)^{n(n-1)/2} n! \cdot x_1^{n-1} \cdots x_{n-1} \) enters, as has just been verified. Therefore \( \rho(P) = n! \). On the other hand, \( s(P) = \text{sgn}(s) \cdot P \), hence all summands are equal to the denominator, and therefore on the right side we also obtain \( n! \).

### 4.3 Topological preliminaries

Let \( X \) and \( Y \) be compact, oriented manifolds. In the following we always consider, if nothing different is said, (co-) homology groups with coefficients in \( \mathbb{Z} \). By Poincaré duality, \( H^\ast(X) \cong H_\ast(X) \); more precisely, \( H^i(X) \cong H_{n-i}(X) \), where \( n = \dim X \).

**Let** \( f : X \to Y \) **be a continuous map.** Then \( f \) induces maps \( f^* : H^\ast(Y) \to H^\ast(X) \) and \( f_* : H_\ast(X) \to H_\ast(Y) \) on the cohomology, resp. homology level. Poincaré duality \( p \) now yields also a mapping \( f_* : H^\ast(X) \to H^\ast(Y) \), more precisely

\[
\begin{array}{ccc}
H^i(X) & \xrightarrow{f_*} & H^{m-n+i}(Y) \\
\downarrow p & & \downarrow p \\
H_{n-i}(X) & \xrightarrow{f_*} & H_{n-i}(Y),
\end{array}
\]

where \( m = \dim Y \). For \( b \in H^m(X) \) we have \( f_*(b) \in H^m(Y) \) and

\[
b[X] = f_* b[Y],
\]

where \([X]\) and \([Y]\) again denote the fundamental cycles of \( X \) and \( Y \). Since \( H^\ast(X) \) is a ring and \( f^* : H^\ast(Y) \to H^\ast(X) \) is a ring homomorphism, \( H^\ast(X) \) is also a module over \( H^\ast(Y) \) and for \( a \in H^\ast(Y), b \in H^\ast(X) \) we have

\[
f_*(f^*(a) \cdot b) = a \cdot f_*(b),
\]

i.e. \( f_* \) is an \( H^\ast(Y) \)-module homomorphism.
Let \( f : X \to Y \) be a fibre bundle where the fibre \( A \) is a compact, oriented manifold. Then one has:

\[
\begin{align*}
f_* : H^* (X) &\to H^* (Y), \\
f_* : H^i (X) &\to H^{i - \dim A} (Y).
\end{align*}
\]

**Remark:** In the differentiable case one can regard this mapping \( f_* \) in de Rham cohomology as integration of differential forms over the fibres.

From now on, let \( X \) and \( Y \) as well as \( f : X \to Y \) be differentiable. We define a sub-bundle \( X^\Delta \) of the tangent bundle \( TX \) of \( X \). The fibre of \( X^\Delta \) over a point \( x \in X \) is formed from all tangent vectors at the point \( x \) which are tangent to the fibre \( A \) through \( x \). We call this bundle \( X^\Delta \) the bundle along the fibres. The restriction of \( X^\Delta \) to a fibre is isomorphic to the tangent bundle to \( A \). We have:

\[
TX \cong X^\Delta \oplus f^* TY.
\]

**Example:** For a product \( X \cong Y \times A \), \( TX \cong \pi^* TA \oplus f^* TY \), where \( \pi \) is the projection of \( X \) onto \( A \).

Now let \( Q(x) \) be an even power series in \( x \) with coefficients some integral domain \( \mathbb{R} \) over \( \mathbb{Q} \). The corresponding multiplicative sequence for a bundle \( E \) is then \( K(E) = K_Q(E) = \sum_{i=0}^{\infty} K_i(p_1, \ldots, p_i) \), where \( p_i = p_i(E) \). Then we have:

\[
\begin{align*}
K(TX) &= K(X^\Delta) \cdot f^* K(TY) \\
\Rightarrow \quad K(X) &= K(TX)[X] \\
&= f_* (f^* K(TY) \cdot K(X^\Delta))[Y] \\
&= (K(TY) \cdot f_* K(X^\Delta))[Y].
\end{align*}
\]

By evaluation on a point in \( Y \) one obtains:

\[
\begin{align*}
f_* K(X^\Delta) &= K(A) \cdot 1 + (\text{higher terms}) \\
\Rightarrow \quad K(X) &= (K(TY) \cdot (K(A) \cdot 1 + (\text{higher terms})))[Y].
\end{align*}
\]

The higher terms must be present if the genus \( K \) does not behave multiplicatively for the fibre bundle. Therefore we make the following

**Definition:** The genus corresponding to the power series \( Q \) is called strictly multiplicative in the fibre bundle \( f : X \to Y \) with fibre \( A \) if \( f_* K(X^\Delta) = K(A) \cdot 1 \in H^0(Y; \mathbb{R}) \).

Thus we obtain the

**Proposition:** If \( K \) is strictly multiplicative, then \( K(X) = K(Y) \cdot K(A) \).
4.4 The splitting principle

Let $E \to Y$ be a complex vector bundle over a compact, oriented, differentiable manifold $Y$. The flag manifold $F(V)$ belonging to a complex vector space $V$ of dimension $n$ consists of all flags of subspaces of $V$ of length $n$. For the vector space $V \cong \mathbb{C}^n$ with its standard basis we have $F(n) := F(\mathbb{C}^n) = U(n)/T^n$, where $T^n = (U(1))^n \cong (S^1)^n$ is the standard maximal torus in $U(n)$. Notice further that two flag manifolds over different vector spaces of equal dimension, but lacking canonical isomorphism, are not canonically isomorphic.

We now consider the bundle $\sigma_n : F_n \to Y$, which has as fibre $A$ over each point $x \in Y$ the flag manifold of the corresponding fibre of $E$ ($F_n$ is the $F(n)$-bundle associated to $E$, having structure group $U(n)$). In addition, we form in the same manner still further $U(n)$-bundles $\sigma_i : F_i \to Y$, having the fibres

$$U(n)/(T^i \times U(n-i)) = U(n)/(U(1)^i \times U(n-i))$$

(increasing flags of length $i$). Between consecutive bundles there is a natural projection $\tau_i : F_i \to F_{i-1}$ with fibre

$$\frac{U(n)/(T^i \times U(n-i))}{U(n)/(T^{i-1} \times U(n-i+1))} \cong \frac{U(n-i+1)}{T^i \times U(n-i)} \cong P_{n-i}(\mathbb{C}).$$

With this definition we have $\sigma_n = \tau_1 \tau_2 \cdots \tau_n$, and we define the projection $\pi_i$ by $\pi_i := \tau_{i+1} \cdots \tau_{n-1} \tau_n$, so that $\pi_i : F_n \to F_i$, with respect to which $F_n$ is a bundle with fibre $U(n-i)/T^{n-i} \cong F(n-i)$.

A point in a fibre of $F_1$ canonically represents a line in the corresponding fibre of $E$. Therefore $F_1$ is the projectivized bundle $PE$. If one pulls back $E$ to $F_1$ by means of $\sigma_1$, then over each point of $F_1$ one has a distinguished line in the fibre of the pulled-back bundle over this point, and can so split off a line bundle $L_1$,

$$\sigma_1^*(E) = L_1 \oplus E_1.$$ 

Now a point in a fibre of $F_2$ that lies over some point $L$ in $F_1$, canonically represents a flag of length 2 which consists of the line given by the point $L$ in $F_1$ and a plane containing this line. So this flag can alternatively be given by a line in the complement of $L$, i.e. a line in the fibre of $E_1$ over $L$ in $F_1$. Therefore $F_2$ is the projectivized bundle $PE_1$ and we can proceed inductively, and $\sigma_i^*E$ automatically splits off $i$ line bundles,

$$\sigma_i^*E = L_1 \oplus \cdots \oplus L_i \oplus E_i,$$

where $E_i$ is a vector bundle of rank $n-i$. 

Thus we have the following diagram:

\[
\begin{array}{ccc}
L_1 \oplus \cdots \oplus L_n & \rightarrow & F_n \\
\downarrow & & \downarrow \pi_i \\
L_1 \oplus \cdots \oplus L_i \oplus E_i & \rightarrow & F_i \\
\downarrow & & \downarrow \sigma_i \\
L_1 \oplus E_1 & \rightarrow & F_i \\
\downarrow f & & Y \\
E & & \\
\end{array}
\]

The line bundles \(L_i\) restricted to a fibre of \(F_i \rightarrow F_{i-1}\) are tautological bundles. Let them have first Chern classes \(x_i \in H^2(F_i; \mathbb{Z})\). One deduces (consider the Leray spectral sequence, or more simply apply the Leray-Hirsch theorem) that \(H^*(F_i; \mathbb{Z})\) is freely generated as a module over \(H^*(F_{i-1}; \mathbb{Z})\) by \(1, x_i, \ldots, x_i^{n_i},\) and the mapping \(\tau^* : H^*(F_{i-1}; \mathbb{Z}) \rightarrow H^*(F_i; \mathbb{Z})\) is injective; we can therefore consider the cohomology rings as subrings of \(H^*(F_n; \mathbb{Z})\), and with this identification we have:

\[
\sigma_n^*E = L_1 \oplus \cdots \oplus L_n,
\]

\[
c(E) = \sigma_n^*c(E) = (1 + x_1) \cdots (1 + x_n).
\]

Let \(F_i^\Delta\) be the bundle along the fibres of the fibre bundle \(\tau_i : F_i \rightarrow F_{i-1}\). Then we have the following (cf. [Hi56], Theorem 13.1.1 e)

**Lemma:** \(F_i^\Delta \cong E_i \otimes L_i^{-1}\).

**Proof:** Restricted to the fibres (i.e. in the special case that \(Y\) is a point) we have \(F_i^\Delta = TP_{n-1}\). One has the exact sequence of vector bundles

\[
0 \rightarrow 1 \rightarrow n \cdot H^* \rightarrow TP_{n-1} \rightarrow 0.
\]

Here, \(1\) is a trivial line bundle and \(H\) is the tautological line bundle, hence is the restriction of \(L_1\) to the fibre. We have

\[
n \cdot H^* = n \cdot 1 \otimes H^* = (H \oplus \tilde{E}_1) \otimes H^*.
\]

where \(H \otimes H^*\) is the image of the trivial line bundle in the above sequence and \(\tilde{E}_1\) is the restriction of \(E\) to the fibre. Since the sequence splits, it follows that

\[
TP_{n-1} \cong \tilde{E}_1 \otimes H^*.
\]

From the functoriality of the construction, the statement for \(F_i^\Delta\) now follows. For \(F_i^\Delta\) with \(i > 1\) one obtains the result inductively, by carrying out the construction for the bundle \(E_{i-1} \rightarrow F_{i-1}\).
From the lemma we therefore obtain the following formulas:
\[ \pi_i^* F_i^\Delta = L_{i+1} \otimes L_i^{-1} \otimes \cdots \otimes L_n \otimes L_i^{-1}, \]
\[ \pi_i^* c(F_i^\Delta) = (1 + x_{i+1} - x_i) \cdots (1 + x_n - x_i). \]

For the bundle \( F^\Delta \) along the fibres of the map \( \sigma_n \) we therefore have
\[ c(F^\Delta) = c(\pi_i^* F_i^\Delta \otimes \cdots \otimes \pi_n^* F_n^\Delta) = \prod_{i>j} (1 + x_i - x_j). \]

In the algebraic preliminaries we obtained from
\[(t + x_1) \cdots (t + x_n) = t^n + t^{n-1} \cdot c_1 + \cdots + c_n, \]
by the substitution \( t = 1 - x_1 \), the identity
\[(1 + x_2 - x_1) \cdots (1 + x_n - x_1) = (1 - x_1)^n + (1 - x_1)^{n-1} \cdot c_1 + \cdots + c_n. \]

We apply this to the total Chern class of \( F_1^\Delta \) and see that
\[ c(F_1^\Delta) = (1 - x_1)^n + (1 - x_1)^{n-1} \cdot c_1 + \cdots + c_n \in H^*(F_1; \mathbb{Z}), \]
where \( c_i \) are the pulled-back Chern classes of \( E \).

For the cohomology of the flag manifold over a vector space \( V \) of dimension \( n \) we have the following

**Lemma:** The Euler number of the flag manifold is \( n! \).

**Proof:** We consider the trivial bundle \( V \) over a point. \( F_n \) is then the flag manifold of \( V \) and
\[ H^*(F(V); \mathbb{Z}) = \mathbb{Z}[x_1, \ldots, x_n]/(c_1, \ldots, c_n). \]

Therefore, as a \( \mathbb{Z} \)-module \( H^*(F(V); \mathbb{Z}) \) has the basis elements \( x_1^{i_1} \cdots x_n^{i_n} \) with \( 0 \leq i_j \leq n - j \). Since these all lie in even dimensions and their number is \( n! \), the assertion follows, for the Euler number is equal to the alternating sum of the Betti numbers.

Alternatively, one can also use the multiplicativity of the Euler number. Since \( e(P_k) = k + 1 \) and \( F(n) \) is fibered into \( P_1, \ldots, P_{n-1} \), we have
\[ e(F(n)) = e(P_1) \cdots e(P_{n-1}) = n!. \]

**Lemma:** \( \sigma_{n*} \left( \prod_{i>j} (x_i - x_j) \right) = n! \).

**Proof:** Since the dimension of \( \prod_{i>j} (x_i - x_j) \) is exactly \( n(n-1) \) and \( \sigma_{n*} \) lowers the dimension by \( n(n-1) \), it suffices to evaluate the expression over a point \( P \):
\[ \sigma_{n*} \left( \prod_{i>j} (x_i - x_j) \right)[P] = \left( \prod_{i>j} (x_i - x_j) \right)[F(n)] \]
\[ = c_n(F^\Delta)[F(n)] = e(F(n)) = n!. \]

Here we have used the fact that in the fibre over a point \( P \), the bundle \( F^\Delta \) is isomorphic to \( TF(n) \).
4.5 Integration over the fibre

Now we shall turn our attention to the integration over the fibre.

**Theorem:** With \( Q(x) = x/f(x) \) and \( f(x) = x + \cdots \) an odd power series, there holds for \( F_1^\Delta \):

\[
\sigma_1^* K_Q(F_1^\Delta) = \sum_{i=1}^{n} \prod_{j \neq i} \frac{1}{f(x_j - x_i)}.
\]

**Proof:** Let \( a \) be a symmetric expression in the \( x_i \), therefore a polynomial in the \( c_j \). With our identification \( a = \sigma_n^*(a) \), for an element \( b \in H^*(F_n; \mathbb{Z}) \) we have \( \sigma_n^*(a \cdot b) = \sigma_n^*(\sigma_n^*a \cdot b) = a \cdot \sigma_n^*b \).

In addition, \( \sigma_n^* \) is naturally additive, hence is \( \mathbb{Z}[c_1, \ldots, c_n] \)-linear. Furthermore, the cohomology dimension of an element is lowered by \( n(n-1) \) under the mapping \( \sigma_n^* \). Since \( H^*(F_n; \mathbb{Z}) \) is generated, as a module over \( H^*(Y; \mathbb{Z}) \), by the elements \( x_1^{i_1} \cdots x_n^{i_n} \) with \( 0 \leq i_j \leq n-j \), and the mapping \( \sigma_n^* \) is \( \mathbb{Z}[c_1, \ldots, c_n] \)-linear with \( \sigma_n^* \left( \prod_{i>j} (x_i - x_j) \right) = n! \), it coincides with the map \( \rho \) occurring in section 4.2.

If we apply the above to the bundle \( E_1 \rightarrow F_1 \), then we obtain (inductive construction of \( F_i \))

\[
\pi_1^* \left( \prod_{i>j \geq 2} (x_i - x_j) \right) = (n-1)!
\]

\[
\Rightarrow (n-1)! \cdot \sigma_1^*(K_Q(F_1^\Delta)) = (n-1)! \cdot \sigma_1^*(Q(x_2 - x_1) \cdots Q(x_n - x_1))
\]

\[
= \sigma_1^* \left( \prod_{i>j \geq 2} (x_i - x_j) \cdot Q(x_2 - x_1) \cdots Q(x_n - x_1) \right)
\]

\[
= \sigma_n^* \left( \prod_{i>j \geq 2} (x_i - x_j) \cdot Q(x_2 - x_1) \cdots Q(x_n - x_1) \right)
\]

\[
= \sum_{s \in S_n} sgn(s) \cdot s \left( \prod_{i>j \geq 2} (x_i - x_j) \cdot Q(x_2 - x_1) \cdots Q(x_n - x_1) \right)
\]

\[
= \sum_{s \in S_n} s \left( \prod_{i>j} (x_i - x_j) \right) \cdot Q(x_2 - x_1) \cdots Q(x_n - x_1)
\]

\[
= \sum_{s \in S_n} s \left( Q(x_2 - x_1) \cdots Q(x_n - x_1) \right)
\]

\[
= (n-1)! \sum_{i=1}^{n} \prod_{j \neq i} \frac{Q(x_j - x_i)}{(x_j - x_i)}
\]

\[
= (n-1)! \sum_{i=1}^{n} \prod_{j \neq i} \frac{1}{f(x_j - x_i)}.
\]
Here we have used the fact that $S_n$ is the disjoint union of the $S_{n-1} \cdot \tau_{ii}$, where $\tau_{ii}$ transposes 1 and $i$. As we know from the algebraic preliminaries, the result is in fact a polynomial in the $c_j$.

**Corollary:** The genus belonging to the power series $Q(x) = x/f(x)$ is strictly multiplicative in bundles with fibre $P_{n-1}(C)$ if and only if the following identity holds:

$$\sum \prod_{i=1}^n \frac{1}{f(x_j - x_i)} \equiv c.$$  
This constant $c$ is then the value of the genus on $P_{n-1}(C)$.

### 4.6 Multiplicativity and strict multiplicativity

We now want to find power series $f(x)$ which behave strictly multiplicatively in fibre bundles with fibre $P_{n-1}(C)$ (cf. [Oc87]). We have just seen that the genus associated to $Q(x) = x/f(x)$ is strictly multiplicative in such fibre bundles if and only if there holds:

$$K_Q(P_{n-1}(C)) \equiv \frac{1}{f(x_2 - x_1) \cdots f(x_n - x_1)} + \cdots + \frac{1}{f(x_1 - x_n) \cdots f(x_{n-1} - x_n)}.$$

**Proposition:** For a genus $\varphi$ the following are equivalent:

1) $\varphi$ is an elliptic genus,
2) $\varphi$ is strictly multiplicative in fibre bundles with fibre $P_{2n-1}(C)$ for all $n$,
3) $\varphi$ is strictly multiplicative in fibre bundles with fibre $P_3(C)$.

**Proposition:** For a genus $\varphi$ the following are equivalent:

1) $\varphi$ is up to normalization (i.e. passage to $f(ax)/a$) the $L$-genus,
2) $\varphi$ is strictly multiplicative in fibre bundles with fibre $P_n(C)$ for all $n$,
3) $\varphi$ is strictly multiplicative in fibre bundles with fibre $P_2(C)$.

**Remark:** Notice 3) $\Rightarrow$ 2)!

**Proof of the propositions:** The proof of both propositions follows directly from the following lemmata.

**Lemma:** 1) $\Rightarrow$ 2) for elliptic genera.

**Proof:** For all $x_1, \ldots, x_n \in \mathbb{C}$, with $x_i$ pairwise distinct modulo $L$, the function

$$h(x) := \frac{1}{f(x - x_1) \cdots f(x - x_n)}$$
is elliptic with respect to $L$ for even $n$ (cf. section 2.2). Therefore, according to the residue theorem we have:

$$0 = (-1)^{n-1} \sum_{x \in \mathbb{C}/L} \text{res}_x h$$

$$= \frac{1}{f(x_2 - x_1) \cdots f(x_n - x_1)} + \cdots + \frac{1}{f(x_1 - x_n) \cdots f(x_n - x_1)}.$$ 

Since the $x_i$ were arbitrary, this identity also holds for the formal power series. Further, since the coefficients of the power series $f$ are polynomials in $\epsilon$ and $\delta$, the above identity also holds for degenerate lattices on grounds of continuity.

For odd $n$, elliptic genera are in general not strictly multiplicative. For then the function considered above is only elliptic with respect to a lattice $\tilde{L}$ of index two in $L$. Therefore all poles appear doubled, but with opposite signs. Hence the whole expression on the right side cancels, and one obtains no information.

**Lemma:** 1) $\Rightarrow$ 2) for the $L$-genus.

**Proof:** For the function $\tanh(x)$, the fundamental mesh (period parallelogram) of the lattice $L$ degenerates to a fundamental strip $H = \{z \in \mathbb{C} | 0 \leq \text{Im}(z) \leq \pi i\}$ (tanh has the period $\pi i$). The pole set of $1/f(x)$ is $\mathbb{Z} \pi i$. For the symmetrized sum therefore holds:

$$\sum_{i=1}^{n} \prod_{j \neq i} \frac{1}{\tanh(x_j - x_i)} = \sum_{x \in H} \text{res}_x \frac{(-1)^{n-1}}{\tanh(x - x_1) \cdots \tanh(x - x_n)}.
$$

If one now attempts to calculate this residue sum by integrating the function

$$h(x) = \frac{1}{\tanh(x - x_1) \cdots \tanh(x - x_n)}$$

over the boundary of the fundamental strip $H$, one finds that:

$$h(x) \to \begin{cases} (-1)^n, & \text{for } x \to -\infty, \\ 1, & \text{for } x \to \infty. 
\end{cases}$$

Since the fundamental strip has width $\pi i$, integration over the fundamental strip gives for the sum of the residues the value 0 for even $n$ and 1 otherwise, so is constant in every case.

**Remark:** 2) $\Rightarrow$ 3) is trivial.

**Lemma:** 3) $\Rightarrow$ 1).

**Proof (exercise):** Let $f(x)$ be an odd power series. Show by power series calculations:

i) If $f$ satisfies the identity

$$\sum_{i=1}^{3} \prod_{j \neq i} \frac{1}{f(x_j - x_i)} \equiv c,$$
then up to normalization \( f(x) = \tanh(x) \).

ii) If \( f \) satisfies the identity
\[
\sum_{i=1}^{4} \prod_{j \neq i} \frac{1}{f(x_j - x_i)} \equiv 0,
\]
then \( f \) belongs to an elliptic genus (namely show: \( f \) is uniquely determined by the coefficients of \( x^3 \) and \( x^5 \)).

**Remark:** Alternatively, one can also prove this lemma by constructing a basis sequence in which all spaces are total spaces of fibre bundles, with fibre \( P_2(\mathbb{C}) \) for the \( L \)-genus, resp. \( P_3(\mathbb{C}) \) for the elliptic genera. One then argues inductively over the dimension of the manifold.

In order to deduce 1) from 2) without the characterization 3), one can proceed exactly as in the proof of the theorem of Borel and Hirzebruch in section 4.1. We recall the Milnor manifolds: These form for \( i = 3 \) and \( j = 2k - 2, k \geq 1 \) (thus \( \dim H_{ij} = 4k \) a basis sequence (since then \( s_k(H_{ij}) \neq 0 \)). In this situation, for \( k \geq 3 \) the manifold \( H_{3,2k-2} \) fibres over \( P_3(\mathbb{C}) \) with fibre \( P_{2k-3}(\mathbb{C}) \) being a projective space of odd dimension. Since \( H_{3,0} = P_2(\mathbb{C}) \) and \( H_{3,2} = H_{2,2} \), the implication 2) \( \Rightarrow \) 1) is thereby proved.

In particular, we then have
\[
\varphi(P_2(\mathbb{C})) = \delta, \quad \varphi(H_{2,2}) = \varepsilon, \quad \text{and} \quad \varphi(H_{3,2k-2}) = 0 \text{ for all } k \geq 3.
\]

A more general result on multiplicativity in fibre bundles has been proved by Taubes and Bott-Taubes (cf. [Ta88], [BoTa89]). We give a reformulation using [Oc86], Proposition 1.

**Theorem:** Let \( M \rightarrow B \) be a fibre bundle with a compact, oriented, spin manifold \( F \) as fibre and compact, connected \( \pi_1 \)-group as structure group. Then every elliptic genus is multiplicative, i.e. \( \varphi(M) = \varphi(F) \cdot \varphi(B) \).

In order to make the difference between multiplicativity and strict multiplicativity vanish, we now have a

**Theorem** (Borel, Hirzebruch): Let \( F \) be a fixed compact, oriented, differentiable manifold. Further, let \( \mathcal{F}_F \) be the category of all fibre bundles \( \pi : M \rightarrow B \) with fibre \( F \), where all manifolds considered are compact, oriented and differentiable and \( \pi_1(B) \) operates trivially on \( H^*(F; \mathbb{Q}) \). If \( \varphi \) is a multiplicative genus, i.e. \( \varphi(M) = \varphi(F) \cdot \varphi(B) \) for all these fibre bundles then \( \varphi \) is also strictly multiplicative in these fibre bundles, i.e. \( \pi_*(K_{\varphi}(M^\delta)) = \varphi(F) \cdot 1 \in H^0(B; \mathbb{Q}) \).

**Proof** (cf. [BoHi59]): According to Thom [Th54], the submanifolds of a compact, oriented, differentiable manifold generate the rational homology (a suitable multiple of every homology class can be represented by a \( \mathbb{Z} \)-linear combination of submanifolds).
We now proceed inductively as follows: Let \( \varphi \) be strictly multiplicative up to dimension \( k \). Let \( K \) be the multiplicative sequence belonging to \( \varphi \). For the bundle \( M^\Delta \) along the fibres holds:

\[
\pi_*(K(M^\Delta)) = \varphi(F) + a_k + a_{k+1} + \cdots,
\]

where the \( a_j \in H^j(B;\mathbb{Q}) \). Now let \( X \) be a \( k \)-dimensional submanifold of \( B \). The fundamental group \( \pi_1(X) \) again acts trivially on \( H^*(F;\mathbb{Q}) \). We now restrict the fibre bundle to \( X \). Then we have

\[
\pi_*(K(M^\Delta|_X)) = \varphi(F) + a_k + 0
\]

restricted to \( X \). Now we have:

\[
\varphi(X) \cdot \varphi(F) = \varphi(\pi^{-1}(X))
\]

\[
= (K(\pi^*TX) \cdot K(M^\Delta|_X))[\pi^{-1}X]
\]

\[
= (K(TX) \cdot \pi_*K(M^\Delta|_X))[X]
\]

\[
= ((1 + \cdots + \varphi(X) \cdot g_x) \cdot (\varphi(F) + a_k))[X]
\]

\[
= (\varphi(x) \cdot \varphi(F) \cdot g_x + a_k)[X]
\]

\[
\Rightarrow a_k[X] = 0 \quad \text{for all } X
\]

\[
\Rightarrow a_k = 0.
\]

**Corollary:** The \( L \)-genus (signature) is strictly multiplicative in all differentiable bundles (with \( \pi_1(B) \) acting trivially on \( H^*(F;\mathbb{Q}) \)).

**Example:** Let \( M \) and \( B \) be manifolds, \( \dim M = 8 \), \( \dim B = 4 \) and let \( M \) be total space of a fibre bundle with fibre \( F \) and base \( B \). Then the vector bundle \( M^\Delta \) has the Pontrjagin classes \( p_1 \in H^4(M;\mathbb{Z}) \) and \( p_2 = e^2 \in H^8(M;\mathbb{Z}) \). For the multiplicative sequence of the signature there holds in dimension 8:

\[
L_2 = (7p_2 - p_1^2)/45.
\]

Now \( \pi_*(L_2(M^\Delta)) = 0 \), for in view of the strict multiplicativity of the signature we have \( \pi_*(L(M^\Delta)) = L(F) \cdot 1 \in H^8(B;\mathbb{Q}) \), while \( \pi_*(L_2(M^\Delta)) \) lives in \( H^4(B;\mathbb{Q}) \). Further, \( \pi_* \) is an isomorphism in the highest dimension, since Poincaré duality and \( \pi_* : H_0(M;\mathbb{Z}) \to H_0(B;\mathbb{Z}) \) are both isomorphisms. Hence over \( \mathbb{Q} \) we have \( L_2(M^\Delta) = 0 \), so

\[
e^2 = p_1^2/7,
\]
for the bundle along the fibres of an 8-dimensional manifold fibered over a 4-dimensional manifold.

**Problem:** Is there a bundle (with fibre dimension 4), for which the corresponding equation for the Pontrjagin classes does not hold? (In base dimension 4 there is no torsion, but in higher dimensions it is indeed possible.)

**Example:** Kodaira (cf. [Ko67]) has found a family of manifolds in the complex analytic category which shows that the trivial operation of $\pi_1(B)$ on $F$ is a necessary hypothesis for our theorem. These manifolds are called Kodaira surfaces and are of general type. As complex surfaces, they have real dimension 4, and further they are total space of a fibre bundle with fibre and base a Riemann surface. If the $L$-genus were multiplicative in these fibre bundles, then on dimensional grounds the signature would be zero for these surfaces. However, Kodaira has calculated that the signature of these surfaces is strictly positive.
5  The Atiyah-Singer index theorem

5.1 Elliptic operators and elliptic complexes

Let $X$ be a compact, differentiable manifold of dimension $k$, and let $E$ and $F$ be complex $C^\infty$-vector bundles over $X$ of rank $m$, resp. $n$. Denote by $\Gamma$ the vector space of all $C^\infty$-sections of a bundle, and let $D : \Gamma(E) \to \Gamma(F)$ be a $\mathbb{C}$-linear map. Each $f \in \Gamma(E)$ can be written over a trivializing neighborhood $U$ of a point $x \in X$ as $f = (f_1, \ldots, f_m)$, where the $f_i$ are $C^\infty$-functions over $U$. In the same way the image $g = D(f)$ can be written locally as $g = (g_1, \ldots, g_n)$.

**Definition:** $D$ is called a differential operator of order $p$ if there is an $m \times n$ matrix $(d_{ij})$ with

$$(g_1, \ldots, g_n) = (f_1, \ldots, f_m) \cdot (d_{ij}),$$

where the $d_{ij}$ are polynomials in the $\frac{\partial}{\partial x_r}$ of degree (at most) $p$ with differentiable functions as coefficients.

Here it is not required that the order $p$ be chosen minimally. Let $\pi$ denote the projection of the fibre bundle $\pi : T^*X \setminus 0_X \to X$, i.e. the cotangent bundle with the zero section $0_X$ removed. To a differential operator $D$ of order $p$ we now define the $p$-symbol

$$\sigma^{(p)}(D) : \pi^*E \to \pi^*F$$

as follows (cf. [We80], p. 115):

For $0 \neq v \in T^*(X)$ and $g$ a $C^\infty$-function on $X$ with $dg = v$ and $f(x) = e \in E_x$, put

$$\sigma^{(p)}(D)(x,v)e := D\left(\frac{v^p}{p!}(g - g(x))^p \cdot f\right)(x).$$

In order to describe the symbol locally, we form the matrix $(d_{ij}^{(p)})$, in which $d_{ij}^{(p)}$ is the homogeneous component of $d_{ij}$ of degree $p$. For $x \in X$ and $v = (v_1(v), \ldots, v_n(v)) \in T^*_x X$ we replace the $\frac{\partial}{\partial x_r}$ by $iv_r$ in $(d_{ij}^{(p)})$ and obtain a matrix $(\sigma^{(p)}_{ij}(v))$. This is independent of the chosen chart of the manifold, since the $v_r$ (coordinate functions of $T^*_x X$) and the $\frac{\partial}{\partial x_r}$ (basis of $T_x X$) coincide. We therefore obtain the $\mathbb{C}$-linear map $(\sigma^{(p)}_{ij}(D)(x,v))$. Obviously, the symbol depends on the order of the differential operator.

**Definition:** A differential operator $D$ of order $p$ is called an elliptic differential operator if $\sigma^{(p)}(D) : \pi^*E \to \pi^*F$ is a bundle isomorphism of $\pi^*E$ onto $\pi^*F$. 

The Atiyah-Singer index theorem

Remark: For an elliptic differential operator the order is therefore well-defined.

Example: On $X = \mathbb{R}^k/L$, where $L \subset \mathbb{R}^k$ is a lattice, the Laplace operator $\Delta := \frac{\partial^2}{\partial x_1^2} + \cdots + \frac{\partial^2}{\partial x_k^2}$ is an elliptic operator of order two on functions, i.e. on sections of the trivial bundle $X \times \mathbb{C}$, for we have $\sigma^{(2)}(\Delta)(x,v) = -(v_1^2 + \cdots + v_k^2) \neq 0$ for $v \neq 0$.

For elliptic differential operators one has the following (cf. [We80]) important

**Theorem:** ker $(D)$ and coker $(D)$ are finite dimensional.

**Remark:** One obtains the statement about the cokernel from the (difficult) statement about the kernel, by considering the adjoint operator.

**Definition:** The index of $D$ is defined by

$$\text{ind}(D) = \dim_{\mathbb{C}} \ker(D) - \dim_{\mathbb{C}} \text{coker}(D).$$

Now let $E_0, \ldots, E_m$ be complex vector bundles over $X$, and for $i = 0, \ldots, m - 1$ let $D_i : \Gamma E_i \to \Gamma E_{i+1}$ be differential operators of degree $p$ with $D_{i+1}D_i = 0$ and corresponding symbols $\sigma_i = \sigma^{(p)}(D_i)$.

**Definition:** Such a complex

$$D : \Gamma E_0 \xrightarrow{D_0} \Gamma E_1 \to \cdots \to \Gamma E_{m-1}$$

is called an elliptic complex if the corresponding complex of symbols

$$0 \to \pi^* E_0 \xrightarrow{\sigma_0} \cdots \xrightarrow{\sigma_{m-1}} \pi^* E_m \to 0$$

is an exact sequence of vector bundles.

**Remark:** If one considers again $\sigma^{(p)}(x,v) : E_i, \pi \to E_{i+1}, \pi$, then the complex is elliptic if and only if the complex of symbols is exact for all $x \in X$ and $v \in T^*_x X \setminus \{0\}$. For $m = 1$, an elliptic complex is precisely an elliptic differential operator.

Since the composition $D_iD_{i-1} = 0$, one can consider the cohomology groups $H^i = \ker(D_i)/\text{im}(D_{i-1})$. From the assertion above for the case $m = 1$ now follows easily the

**Theorem:** For an elliptic complex, all cohomology groups $H^i$ are finite dimensional.

We shall put $h^i : = \dim_{\mathbb{C}} H^i$ when it is clear which elliptic complex is meant.

**Definition:** The index of an elliptic complex $D$ is defined by

$$\text{ind}(D) = \sum_{i=0}^{m} (-1)^i \cdot \dim_{\mathbb{C}} H^i = \sum_{i=0}^{m} (-1)^i \cdot h^i.$$

For $m = 1$, the index of an elliptic complex coincides with the index of the elliptic operator $D_0$. 
5.2 The index of an elliptic complex

Atiyah-Singer Index Theorem: Let $X$ be a compact, oriented, differentiable manifold of dimension $2n$ and $D = (D_i : \Gamma E_i \rightarrow \Gamma E_{i+1})$ an elliptic complex ($i = 0, \cdots, m - 1$), associated to the tangent bundle. Then the index of this complex is determined by the following formula (cf. [AtSi68I], [AtSe68II], [AtSi68III]):

$$\text{ind} (D) = (-1)^n \left( \frac{1}{e(T^*X)} \sum_{i=0}^{m} (-1)^i \cdot \text{ch} (E_i) \right) \text{td} (TX \otimes \mathbb{C}) [X].$$

Remark: In this formula, $\text{td}$ is the multiplicative sequence associated to the power series $Q(x) = x/(1 - e^{-x})$ (the Todd genus, cf. section 1.8). The alternating sum of the Chern characters is in fact divisible by the Euler class; this is a non-trivial fact. It is convenient for calculations to factor the Euler class $x_1 \cdots x_n$ formally out of the Todd class of $TX \otimes \mathbb{C}$. The resulting expression no longer makes sense topologically; for concrete calculations the Euler class always appears as a factor in the Chern characters and corrects this error. We therefore use the formula

$$\text{ind} (D) = \left( \sum_{i=0}^{m} (-1)^i \cdot \text{ch} (E_i) \right) \prod_{j=1}^{n} \left( \frac{x_j}{1 - e^{-x_j}} \cdot \frac{1}{1 - e^{-x_j}} \right) [X].$$

This formula is, however, to be used with caution, since the right product is neither symmetric in the $x_j^2$ nor an invertible power series.

Remark: This theorem gives a purely topological expression for the differentiable invariant $\text{ind} (D)$. In particular, the differential operators themselves make no appearance in the formula. Interpreted differently, one now knows that the complicated expression on the right side is integral.

The examples in the following three sections are complexes of order one.

5.3 The de Rham complex

Let $X$ be a compact, differentiable manifold of dimension $k$ and $T$ its tangent bundle. The bundle of differential forms of degree $i$ with complex-valued coefficients is $E_i = \Lambda^i (T^* \otimes \mathbb{C})$. The exterior derivative $d$ yields an elliptic complex, $d = (d : \Gamma E_i \rightarrow \Gamma E_{i+1})$, whose symbol $\sigma_{i} (x, \nu)$ is the wedge-product $\omega \mapsto \nu \wedge \omega$ (as linear map). The cohomology groups $H^i$ will also be denoted by $H^i_{\text{de Rham}}$. By the theorem of de Rham, we have:

$$H^i_{\text{de Rham}} \cong H^i (X; \mathbb{C}).$$
The Atiyah-Singer index theorem

This means that not only the index of the elliptic complex $d$, but indeed all the individual $h^i = \dim H^i_{\text{de Rham}}$ are topological invariants, which we also denote as Betti numbers $b_i$. Thus

$$\text{ind}(d) = \sum_{i=0}^{k} (-1)^i \cdot h^i = \sum_{i=0}^{k} (-1)^i \cdot b_i = e(X).$$

We now compare this result with the Atiyah-Singer index theorem. For this, let $X$ now be $2n$-dimensional and oriented. As we have seen in section 1.5, we have:

$$\text{ch}\left(\sum_{i=0}^{n} (\Lambda^i(T^* \otimes \mathbb{C})) \cdot y^i\right) = \prod_{j=1}^{n} \left( (1 + ye^{\pi i})(1 + ye^{-\pi i}) \right).$$

For $y = -1$ this is exactly the sum in the Atiyah-Singer index formula. It cancels all factors there apart from the Euler class, and so gives correctly:

$$\text{ind}(d) = (e(TX))[X] = e(X).$$

5.4 The Dolbeault complex

Now let $X$ be a complex $n$-dimensional manifold, $T$ the holomorphic tangent bundle. We have

$$T^*_R \otimes \mathbb{C} \cong T^* \otimes T^*$$

$$\Rightarrow \quad \Lambda^i(T^*_R \otimes \mathbb{C}) \cong \Lambda^i(T^* \otimes T^*)$$

$$\cong \bigoplus_{p+q=i} (\Lambda^p T^* \otimes \Lambda^q T^*).$$

With the notation $A^{p,q} := \Gamma(\Lambda^p T^* \otimes \Lambda^q T^*)$, the exterior derivative $d : A^{p,q} \rightarrow A^{p+1,q} \oplus A^{p+1,q+1}$ splits into $d = \partial + \bar{\partial}$, with $\partial : A^{p,q} \rightarrow A^{p+1,q}$ and $\bar{\partial} : A^{p,q} \rightarrow A^{p,q+1}$. For fixed $p$, $\bar{\partial}$ yields an elliptic complex of differential operators. This is called the Dolbeault complex. Let $H^{p,q}$ be the $q$-th cohomology group of this complex, $h^{p,q} := \dim \mathbb{C} H^{p,q}$. Hence $H^{p,0}$ is the vector space of holomorphic sections of $\Lambda^p T^*$, the bundle of holomorphic $p$-forms on $X$. For $p = 0$ these are the holomorphic functions on $X$, which must be locally constant since $X$ is compact. Hence $h^{0,0}$ is the number of connected components of $X$. The index of $\bar{\partial}$ for fixed $p$ is also denoted by $\chi^p$:

$$\chi^p := \sum_{q=0}^{n} (-1)^q \cdot h^{p,q}.$$
In addition, \( \chi := \chi^0 \) is called the arithmetic genus of \( X \).

We shall now calculate these \( \chi^p \) by means of the Atiyah-Singer index theorem. We reduce the structure group of the holomorphic tangent bundle \( T \) to \( U(n) \), hence can identify \( T^* \) with \( T \). First we consider the case \( p = 0 \). The bundles appearing are then \( \Lambda^0 T^* \cong \Lambda^0 T \). From our earlier result (cf. section 1.5)

\[
\sum_{i=0}^{n} \text{ch} (\Lambda^i T) \cdot y^i = \prod_{j=1}^{n} (1 + y \cdot e^{x_j}),
\]

we obtain, with \( y = -1 \), for the sum in the Atiyah-Singer index theorem the expression \( \prod_{j=1}^{n} (1 - e^{x_j}) \). Hence there remains in the formula only one of the two factors in the product:

\[
\chi^0 = \prod_{j=1}^{n} \left( \frac{x_j}{1 - e^{-x_j}} \right) [X] = \text{td} (T)[X] = \text{td} (X).
\]

For the first three dimensions we have as examples (cf. section 1.8):

\[
n = 1: \quad \chi^0 = \frac{c_1}{2} [X] = \frac{e(X)}{2}, \quad n = 2: \quad \chi^0 = \frac{c_1^2 + c_2}{12} [X], \quad n = 3: \quad \chi^0 = \frac{c_1 c_2}{24} [X].
\]

All \( \chi^0 \) are integral, being the index of an operator. One therefore obtains divisibility conditions on the Chern numbers. For \( n = 1 \), \( \chi^0 \) is half the Euler number, hence \( \chi^0 = 1 - g \) where \( g \) is the usual genus (number of handles) of the Riemann surface.

For general \( p \) we must determine the weights of the representation which leads to \( \Lambda^p T^* \otimes \Lambda^q T^* \), in order to be able to identify the Chern character. If we collect together the results for different \( p \) by putting

\[
\chi_y := \sum_{p=0}^{n} \chi^p \cdot y^p,
\]

we obtain the

**Proposition:** \( \chi_y = \prod_{j=1}^{n} \left( 1 + y \cdot e^{-x_j} \right) \left( \frac{x_j}{1 - e^{-x_j}} \right) [X] \).

**Proof:** This follows easily from the formulas in section 1.5. \( \square \)

**Remark:** The power series \( x(1 + y \cdot e^{-x})/(1 - e^{-x}) \) can unfortunately not be taken as the characteristic power series for a (complex) genus, since it starts with \( 1 + y \) instead of \( 1 \). If we replace \( x \) by \( x(1 + y) \), then we obtain by evaluation on a \( 2n \)-dimensional manifold an additional factor \( (1 + y)^n \), since for the evaluation only the homogeneous
component of degree $n$ in the $x_j$ enters. We therefore obtain:

$$
\chi_y = \prod_{j=1}^{n} \left( (1 + y \cdot e^{-x_j}) \frac{x_j}{1 - e^{-x_j}} \right)[X]
$$

$$
= \prod_{j=1}^{n} \left( \frac{1 + y \cdot e^{-x_j(1+y)}}{1 + y} \cdot \frac{x_j(1+y)}{1 - e^{-x_j(1+y)}} \right)[X]
$$

$$
= \prod_{j=1}^{n} \left( \frac{x_j(1+y \cdot e^{-x_j(1+y)})}{1 - e^{-x_j(1+y)}} \right)[X].
$$

Hence $\chi_y$ is the genus belonging to the power series

$$
Q(x) = \frac{x(1 + y \cdot e^{-x(1+y)})}{1 - e^{-x(1+y)}}.
$$

For three values of $y$, this $\chi_y$-genus is an important invariant:

- $y = 0$:
  $$
  \chi_0 = \sum_{p=0}^{n} \chi^p \cdot 0^p = \chi^0 = \chi \quad \text{(arithmetic genus)}.
  $$

- $y = -1$:
  $$
  \chi_{-1} = \sum_{p=0}^{n} \chi^p \cdot (-1)^p = \sum_{p=0}^{n} (-1)^p \cdot \sum_{q=0}^{n} (-1)^q \cdot h^{p,q}
  $$

  $$
  = \sum_{p,q=0}^{n} (-1)^{p+q} \cdot h^{p,q} = \text{ind}(\overline{d}) = \text{ind}(d) = e(X)
  $$

  (ind $\overline{d}$ = ind $(d)$, since in the Atiyah-Singer index theorem the same bundles, namely $\Lambda^p T^*_\mathbb{R} \otimes \mathbb{C}$, appear).

The characteristic power series for the Euler number can therefore not obviously be normalized (for $y = -1$, the numerator and the denominator of $Q(x)$ both are zero). Nonetheless, an application of l'Hospital's rule yields $Q(x) = 1 + x$.

- $y = 1$:
  As characteristic power series remains

  $$
  \frac{x(1 + e^{-2x})}{1 - e^{-2x}} = \frac{x(e^x + e^{-x})}{e^x - e^{-x}} = \frac{x}{\tanh(x)}.
  $$

  As we already know, this even power series yields the signature of the manifold, so

  $$
  \chi_1 = \sum_{p=0}^{n} \chi^p = \text{sign}(X).
  $$
5.5 The signature as an index

For an $n$-dimensional oriented vector space $V$, provided with a scalar product, one can define a linear map (Hodge $*$-operator) $* : \Lambda^i V \to \Lambda^{n-i} V$. To do so, let $e_1, \ldots, e_n$ be an orthonormal basis of $V$ compatible with the orientation. The mapping $*$ is then defined on a basis of $\Lambda^i V$ by

$$ *(e_{j_1} \wedge \cdots \wedge e_{j_i}) = e_{j_{i+1}} \wedge \cdots \wedge e_{j_n}, $$

where the indices $j_{i+1}, \ldots, j_n$ are ordered so that $e_{j_1} \wedge \cdots \wedge e_{j_n}$ gives the orientation of $V$. This definition does not depend on the choice of orthonormal basis. The scalar product on $V$ induces a scalar product $\langle \cdot, \cdot \rangle$ on $\Lambda^i V$, with respect to which the $e_{j_1} \wedge \cdots \wedge e_{j_i}$, with $j_1 < \cdots < j_i$ form an orthonormal basis. Therefore for $\alpha, \beta \in \Lambda^i V$ and $\omega = e_1 \wedge \cdots \wedge e_n$ we have:

$$ \langle \alpha, \beta \rangle = \langle \alpha, \beta \rangle \cdot \omega. $$

Moreover, one sees easily that $** = (-1)^{(n-i)} \cdot \text{id}$. For this reason we define a map $\tau$ on $\Lambda^i V$ by

$$ \tau := (-1)^{i(i-1)/2+k} * $$

if $\dim V = 4k$. Then $\tau^2 = \text{id}$ holds.

We now compute the signature of a manifold as the index of an elliptic operator (cf. [AtSi68III]). Thus let $X$ be a compact, oriented, differentiable, $4k$-dimensional manifold and let $T$ be its tangent bundle provided with a Riemannian metric. This induces a metric on the bundles $\Lambda^i(T^* \otimes \mathbb{C})$. As above (consider local orthonormal bases) the $*$- and $\tau$-operators can be defined on the exterior powers of the cotangent space and also on the sections $\Lambda^i = \Gamma(\Lambda^i(T^* \otimes \mathbb{C}))$. Then for $\alpha, \beta \in \Lambda^i$ we have

$$ \langle \alpha, \beta \rangle = \int_X \alpha \wedge \tau \beta. $$

Since $\tau^2 = \text{id}$, $\tau$ has the eigenvalues $+1$ and $-1$. We can extend $\tau$ linearly to $\Lambda(T^* \otimes \mathbb{C})$ and obtain the sub-bundles $E_+$ with eigenvalue $+1$ and $E_-$ with eigenvalue $-1$. For $\alpha \in \Lambda^i(T^* \otimes \mathbb{C})$ we have $\alpha + \tau \alpha \in E_+$, $\alpha - \tau \alpha \in E_-$ and $\alpha = \frac{1}{2}((\alpha + \tau \alpha) + (\alpha - \tau \alpha))$, hence $\Lambda(T^* \otimes \mathbb{C}) = E_+ \oplus E_-$. The maps $\alpha \mapsto \alpha \pm \tau \alpha$
are injective for \( \alpha \in \Lambda^i(T^* \otimes \mathbb{C}) \) with \( i < 2k \), and because of the dimension shift the rank of \( E_\pm \) is therefore greater than or equal to \( \sum_{i=0}^{2k-1} \binom{4k}{4k-2i} \). In the critical case \( i = 2k \) one can easily show that the rank of the bundle \( \mathcal{E} \cap \Lambda^{2k}(T^* \otimes \mathbb{C}) \) is precisely \( \frac{1}{2} \binom{4k}{2k} \). Therefore we have

\[
\text{rk}_\mathbb{C} E_+ = \text{rk}_\mathbb{C} E_- = 2^{4k-1}.
\]

As usual, \( d : A^i \rightarrow A^{i+1} \) is the exterior derivative. We define \( d^* : A^i \rightarrow A^{i-1} \) by \( d^* = -*d* = -*d\tau \). The Hodge *-operator is a differential operator of order zero and \( d \) has order one. For \( \alpha \in A^i \) and \( \beta \in A^{i+1} \) we have:

\[
\langle d\alpha, \beta \rangle = \int_X d\alpha \wedge *\beta
= \int_X (-1)^{i+1} \alpha \wedge d* \beta + \int_X d(\alpha \wedge *\beta)
= \int_X (-1)^{i+1+i(4k-0)+1} \alpha \wedge *(-d\alpha)\beta
= \langle \alpha, d^* \beta \rangle.
\]

Hence \( d^* \) is adjoint to \( d \), and therefore the differential operator \( d + d^* \) is self-adjoint, so its index is zero. Since

\[
\tau (d + d^*) = \tau d - \tau \tau d\tau = \tau d - d\tau = -(d\tau - \tau d)
= -(d\tau + d^* \tau) = -(d + d^*) \tau,
\]

one can consider \( d + d^* : \Gamma \mathcal{E}_+ \rightarrow \Gamma \mathcal{E}_- \).

In order to determine the signature of \( X \), we must decompose \( H^{2k}_{\text{de Rham}} = H^{2k}(X; \mathbb{C}) \) into a positive and a negative definite part with respect to the intersection form. Now in each de Rham cohomology class there is precisely one harmonic form as representative. These are the elements of \( \Gamma(\Lambda(T^* \otimes \mathbb{C})) \) which lie in the kernel of \( (d + d^*)^2 = \Delta \) (Laplace operator) and therefore (since \( d + d^* \) is self-adjoint) are in the kernel of \( d + d^* \). Let \( H^{2k}_+ \) (resp. \( H^{2k}_- \)) be those subspaces of \( H^{2k}(X; \mathbb{C}) \) which correspond to the harmonic forms \( \alpha \) with \( \tau \alpha = \alpha \) (resp. \( \tau \alpha = -\alpha \)). Therefore \( H^{2k}(X; \mathbb{C}) = H^{2k}_+ \oplus H^{2k}_- \) is a decomposition into eigenspaces with respect to \( \tau \), which induces a decomposition of \( H^{2k}(X; \mathbb{R}) \). For a real harmonic form \( \alpha \in H^{2k}_\mathbb{R}, \alpha \neq 0 \), we have:

\[
0 < \langle \alpha, \alpha \rangle = \int_X \alpha \wedge *\alpha = \int_X \alpha \wedge \tau \alpha = \int_X \alpha \wedge \alpha.
\]

For real \( \alpha \in H^{2k}_\mathbb{R}, \alpha \neq 0 \), holds correspondingly:

\[
0 > -\langle \alpha, \alpha \rangle = -\int_X \alpha \wedge *\alpha = -\int_X \alpha \wedge \tau \alpha = \int_X \alpha \wedge \alpha.
\]
Since $\tau$ is self-adjoint on $H^{2k}$, we also have $\int_X \alpha \wedge \beta = 0$ if $\alpha \in H^{2k}_+$ and $\beta \in H^{2k}_-$. Therefore we have decomposed the intersection form on $H^{2k}$ into a positive definite and a negative definite part, and thus

$$\text{sign}(X) = \dim_{\mathbb{C}} H^{2k}_+ - \dim_{\mathbb{C}} H^{2k}_-. $$

Now we consider the operator $d + d^* : \Gamma E_+ \to \Gamma E_-$. This is elliptic, since $(d + d^*)^2 = \Delta$ is the Laplace operator. Its kernel consists of the harmonic forms for the eigenvalue 1 of $\tau$ . The adjoint operator is $d + d^* : \Gamma E_- \to \Gamma E_+$, whose kernel consists of the harmonic forms for the eigenvalue $-1$. In the expression

$$\text{ind}(d + d^*) = \dim \ker (d + d^*) - \dim \operatorname{coker} (d + d^*)$$

$$= \dim \ker (d + d^* : \Gamma E_+ \to \Gamma E_-) - \dim \ker (d + d^* : \Gamma E_- \to \Gamma E_+),$$

the components of harmonic forms away from the middle-dimensional cohomology have the same dimension and so cancel. There only remains

$$\text{ind}(d + d^*) = \dim H^{2k}_+ - \dim H^{2k}_-. $$

Hence the signature of $X$ is precisely the index of $d + d^*$.

Again, we compare the result with the Atiyah-Singer index theorem. For $\text{ch}(E_+) - \text{ch}(E_-)$ one can show (cf. [AtHi59a]):

$$\text{ch}(E_+) - \text{ch}(E_-) = \prod_{j=1}^{2k} (e^{x_j} - e^{-x_j}).$$

We recast the product term in the Atiyah-Singer index theorem slightly:

$$1 - e^{-x_j} = e^{-x_j/2} \cdot \left(e^{x_j/2} - e^{-x_j/2}\right),$$

$$1 - e^{x_j} = e^{x_j/2} \cdot \left(e^{-x_j/2} - e^{x_j/2}\right)$$

$$\Rightarrow \prod_{j=1}^{2k} \left(\frac{x_j}{1 - e^{-x_j}} \cdot \frac{1}{1 - e^{x_j}}\right) = \prod_{j=1}^{2k} \frac{x_j}{(e^{x_j/2} - e^{-x_j/2})^2}$$

$$\Rightarrow \text{sign}(X) = \left(\prod_{j=1}^{2k} (e^{x_j} - e^{-x_j}) \prod_{j=1}^{2k} \frac{x_j}{(e^{x_j/2} - e^{-x_j/2})^2}\right)[X]$$

$$= \left(\prod_{j=1}^{2k} \frac{x_j}{(e^{x_j/2} - e^{-x_j/2})^2}\right)[X]$$

$$= \left(\prod_{j=1}^{2k} \frac{x_j}{\tanh (x_j/2)}\right)[X] = \frac{1}{2^{2k}} \left(\prod_{j=1}^{2k} \frac{2x_j}{\tanh (x_j)}\right)[X]$$

$$= \left(\prod_{j=1}^{2k} \frac{x_j}{\tanh (x_j)}\right)[X].$$
One obtains the next-to-last equation by replacing $x_j$ with $2x_j$. Since we evaluate over $X$, only the homogeneous components of degree $2k$ in the $x_j$ must agree, and therefore one must divide by $2^{2k}$.

5.6 The equivariant index

Now let $X$ be a compact, complex manifold of complex dimension $n$ and as before let $D = (D_i : \Gamma E_i \to \Gamma E_{i+1})$ be an elliptic complex. We want to generalize the Atiyah-Singer index theorem to the case in which a compact topological group $G$ acts on $X$ by holomorphic maps (cf. [AtBo71], [AtSi68III]). Let $X^g = \{ x \in X | gx = x \}$ denote the fixed point set under the operation of a fixed group element $g \in G$. This is a complex submanifold of $X$, which is not necessarily connected. We therefore decompose $X^g = \bigcup X^g_e$ into its connected components. The $X^g_e$ are connected submanifolds of $X$ of possibly different dimensions. In addition, assume that $G$ acts on the elliptic complex, i.e. $G$ acts on the bundles $E_i$ (e.g. if all bundles $E_i$ are associated to the tangent bundle of $X$) and this action commutes with the differential operators $D_i$. Then $G$ also acts on the cohomology groups $H^i$ of the complex. Hence, for each element $g \in G$ the trace $\text{tr}(g, H^i)$ of the action of $g$ on $H^i$ is defined.

**Definition:** In the above situation the **equivariant index** $\text{ind}(g, D)$ of $D$ is defined as

$$\text{ind}(g, D) := \sum_{i=0}^{m} (-1)^i \cdot \text{tr}(g, H^i).$$

**Example:** $\text{ind}(D) = \text{ind}(\text{id}, D)$.

**Example:** The index of the Dolbeault complex is $\chi^p(X) = \sum_{q=0}^{n} (-1)^q \cdot \dim H^{p,q}$. The spaces $H^{p,q}$ are derived from the complex structure of the manifold $X$. If $g$ is a holomorphic automorphism of $X$, then $g$ acts on all $H^{p,q}$. The equivariant index is then:

$$\chi^p(g, X) = \sum_{q=0}^{n} (-1)^q \cdot \text{tr}(g, H^{p,q}).$$

We now want to indicate how one computes the equivariant index as a sum of contributions $\alpha(X^g_e)$ corresponding to the fixed point components $X^g_e$. Let $Y = X^g_e$ be one of the fixed point components of $X$ for an element $g \in G$. For a point $p \in Y$, $g$ acts linearly on the tangent space $T_pX$. There exists a Hermitian metric on $TX|_Y$ so that $g$ acts unitarily on $TX|_Y$. Therefore $T_pX$ decomposes into the direct sum of eigenspaces $N_{p,\lambda}$ for eigenvalues $\lambda$ of modulus one. Since $G$ acts continuously on $X$, one further obtains an eigenbundle $N_{\lambda}$ over $Y$. Indeed, $N_1$ is precisely the tangent
5.6 The equivariant index

bundle \( T_Y \) to \( Y \). Under variation of the point \( p \) in \( Y \), the eigenvalues cannot change since they depend only on the isomorphism type of the representation on \( T_pX \) of the subgroup generated by \( g \), and the representation ring of this subgroup is discrete. With \( d_\lambda = \text{rk } N_\lambda \) we therefore have:

\[
TX|_Y = \bigoplus_\lambda N_\lambda, \quad c(N_\lambda) = \prod_{i=1}^{d_\lambda} \left( 1 + x_i^{(\lambda)} \right)
\]

\[
\Rightarrow \quad c(TX|_Y) = \prod_\lambda \prod_{i=1}^{d_\lambda} \left( 1 + x_i^{(\lambda)} \right) = \prod_{i=1}^n (1 + x_i).
\]

This means that each of the formal roots \( x_i \) can be identified with one of the formal roots \( x_i^{(\lambda)} \) belonging to a definite eigenvalue \( \lambda \). The recipe for the calculation of \( a(Y) \) is now as follows:

We consider the original index formula

\[
\text{ind } (D) = \left( \left( \sum_{i=0}^m (-1)^i \cdot \text{ch } (E_i) \right) c_n(X) \prod_{i=1}^n \left( \frac{1}{1 - e^{-x_i}} \cdot \frac{1}{1 - e^{\lambda_i}} \right) \right) [X].
\]

In this formula, we replace \( X \) by \( Y \), \( e^{-x_i} \) by \( \lambda^{-1} \cdot e^{x_i} \) and \( e^{x_i} \) by \( \lambda \cdot e^{-x_i} \) (where \( x_i \) belongs to the eigenvalue \( \lambda \)). We apply the same process to the terms \( \text{ch } (E_i) \). This can obviously be done if the \( E_i \) are associated to the tangent bundle of \( X \). For \( \lambda = 1 \), the term \( 1 - \lambda^{-1} \cdot e^{x_i} \) is not invertible; but those \( x_i \), which belong to the eigenvalue \( 1 \), originate from the tangent bundle to \( Y \) and so cancel with the factor \( c_n(Y) \).

**Example:** Applying this recipe to the \( \chi_y \)-genus, we obtain from

\[
\sum_{p=0}^n \chi^p(X)y^p = \chi_y(X) = \left( \prod_{i=1}^n \left( 1 + y \cdot e^{-x_i} \right) \frac{x_i}{1 - e^{-x_i}} \right) [X]
\]

the equivariant formula

\[
\sum_{p=0}^n \chi^p(g, X) \cdot y^p = \chi_y(g, X) = \sum_{\nu} a(X^\nu),
\]

where we have for each fixed point component \( Y = X^\nu \):

\[
a(Y) = \left( \prod_{\lambda \neq 1} \prod_{i=1}^{d_\lambda} \left( 1 + y \cdot \lambda e^{-x_i^{(\lambda)}} \right) \cdot \prod_{i=1}^{d_1} \left( 1 + ye^{x_i^{(1)}} \right) - \frac{x_i^{(1)}}{1 - e^{-x_i^{(1)}}} \right) [Y].
\]

If we assume in addition that such a fixed point component consists of a single point, i.e. \( \dim Y = 0 \), then all eigenvalues are distinct from \( 1 \); and for the evaluation on \( Y \) only the zero-dimensional component is relevant, hence

\[
a(Y) = \prod_{\lambda} \prod_{i=1}^{d_\lambda} \frac{1 + \lambda y}{1 - \lambda}.
\]
Since the denominator is exactly the characteristic polynomial evaluated at 1, it does not vanish (1 is not an eigenvalue).

For the equivariant Euler number of $X$ we have in the general case
\[ e(g, X) = \chi_{-1}(g, X) = \sum_{\nu} e(\mathcal{X}^{\nu}_{\nu}) = \sum_{\nu} \left( \prod_{i=1}^{d_i} x^{(i)}_i \right) = \sum_{\nu} e(\mathcal{X}^{\nu}_{\nu}), \]
and in the isolated fixed points case
\[ a(Y)_{\nu=-1} = \prod_{\lambda} \prod_{i=1}^{d_\lambda} \frac{1 - \lambda}{1 - \lambda} = 1, \]
what we expected from the above since it is the Euler number of the point $Y$. For the equivariant signature ($n = \dim \mathcal{X}$) we have (again assuming isolated fixed points)
\[ a(Y)_{\nu=1} = \prod_{\lambda} \prod_{i=1}^{d_\lambda} \frac{1 + \lambda}{1 - \lambda} = (-1)^n \frac{\text{char. polynomial} \ (-1)}{\text{char. polynomial} \ (1)}. \]

### 5.7 The equivariant $\chi_y$-genus for $S^1$-actions

Now let $G = S^1$ and let $q \in S^1$ be a topological generator, i.e. the subgroup of $S^1$ generated by $q$ is dense in $S^1$. Every torus has a topological generator. Then we have
\[ X^q = X^{S^1} = \{ x \in X \mid gx = x \text{ for all } g \in S^1 \}. \]
In this situation, the whole group $S^1$ acts on the restriction of the tangent bundle of $X$ to $X^q$, not merely a group element. The irreducible representations of $S^1$ are all one-dimensional, elements $g \in S^1$ acting as multiplication by $g^k$ for fixed $k \in \mathbb{Z}$. If $S^1$ acts on a vector space, then one also writes
\[ V = \bigoplus_{k=-\infty}^{\infty} q^k V_k \]
which means that $V$ is a direct sum $V = \bigoplus_{k=-\infty}^{\infty} V_k$ and $q$ acts on $V_k$ as multiplication by $q^k$. As in section 5.6, we obtain a splitting of $TX|_Y$ (where $Y = X^S_{S^1}$ is a connected component of $X^{S^1}$):
\[ TX|_Y = \bigoplus_{k=-\infty}^{\infty} q^k N_k. \]
The eigenvalues $\lambda$ of $q$ are now all integral powers $q^k$ of $q$.

The equivariant $\chi_y$-genus is then $(d_k = \text{rk } N_k)$

$$\chi_y(q, X) = \sum_{\nu} a(X^S_{\nu})$$

with

$$a(X^S_{\nu}) = \left(\prod_{i=1}^{d_0} x_i^{(1)} \frac{1 + y \cdot e^{-z_i^{(1)}}}{1 - e^{-z_i^{(1)}}} \cdot \left(\prod_{k=0}^{d_h} \prod_{j=1}^{d_{k+1}^{(1)}} \frac{1 + y \cdot q^k e^{-z_j^{(k+1)}}}{1 - q^k e^{-z_j^{(k+1)}}}\right)\right)[X^S_{\nu}].$$

Because $\chi_y(q, X)$ is a finite (alternating) sum of traces of the action of $q$ on finite dimensional vector spaces for which $q$ has only eigenvalues of the form $q^k$, $\chi_y(q, X)$ is a finite Laurent series in $q$. On the other hand, the expression on the right side is a rational function of $q$. Since this holds for all $q \in S^1$, this is in fact an identity in the indeterminate $q$.

We therefore can consider the limit $q \to 0$. For positive $k$ the factors on the right side all tend to $1$, while for negative $k$ we multiply by $q^{-k}$ and see that the factors converge to $-y$. We therefore have

$$a(X^S_{\nu})_{q=0} = \left(\prod_{i=1}^{d_0} x_i^{(1)} \frac{1 + y \cdot e^{-z_i^{(1)}}}{1 - e^{-z_i^{(1)}}} \cdot \left(\prod_{k=0}^{d_h} \prod_{j=1}^{d_{k+1}^{(1)}} (-y)\right)\right)[X^S_{\nu}]$$

$$= \left(\prod_{i=1}^{d_0} x_i^{(1)} \frac{1 + y \cdot e^{-z_i^{(1)}}}{1 - e^{-z_i^{(1)}}}\right)[X^S_{\nu}] \cdot \prod_{k=0}^{d_h} (-y)^{d_{k+1}^{(1)}}$$

$$= \chi_y(X^S_{\nu}) \cdot (-y)^{\sum_{k>0} d_k}.$$ 

Now for the limit $q \to \infty$. This time we obtain the factor $-y$ for positive $k$, and the factor $1$ for negative $k$, so that

$$a(X^S_{\nu})_{q=\infty} = \chi_y(X^S_{\nu}) \cdot (-y)^{\sum_{k>0} d_k}.$$ 

Therefore $\chi_y(q, X)$ has a value for $q = 0$ as well as for $q = \infty$. Since it is a finite Laurent series in $q$, it must be constant in $q$ and

$$\chi_y(q, X) \equiv \chi_y(id, X) = \chi_y(X).$$

In particular, the values of $\chi_y(q, X)$ and so the sum of the $a(X^S_{\nu})$ coincide for $q \to 0$ and for $q \to \infty$.

These considerations are essentially due to Lusztig [Lu71], Kosniowski [Ko70], and Atiyah and Hirzebruch [AtHi70].
Remark: This is also clear directly for a Kähler manifold. The spaces $H^{p,q}$ are then direct summands of the cohomology. Because $S^1$ is connected, each element acts homotopically to the identity, hence acts trivially on the cohomology and so on $H^{p,q}$.

Examples:

$y = -1$:

$$e(X) = \sum_{\nu} e(X^S_{\nu}) \cdot 1 \sum_{k \geq 0} a^\nu_k$$

$$= \sum_{\nu} e(X^S_{\nu})$$

$y = 1$:

$$\text{sign}(x) = \sum_{\nu} \text{sign}(X^S_{\nu}) \cdot (-1) \sum_{k \geq 0} a^\nu_k$$

$$= \sum_{\nu} \text{sign}(X^S_{\nu}) \cdot (-1) \sum_{k \geq 0} a^\nu_k$$

Now assume that all fixed components $X^S_{\nu}$ are zero-dimensional. Then

$$\chi_y(X) = \sum_{\nu} (-y) \sum_{k \geq 0} a^\nu_k = \sum_{\nu} (-y) \sum_{k \geq 0} a^\nu_k$$

$$= \sum_{\nu} (-y)^{n-\sum_{k \geq 0} a^\nu_k}$$

because the eigenvalue 1 ($k = 0$) does not appear. Therefore we have

$$\chi_y(X) = (-y)^n \chi_{y^{-1}}(X) = (-1)^n y^n \cdot \chi_{y^{-1}}(X).$$

This relation means that the polynomial $\chi_y(X)$ is symmetric in the coefficients of the $y$-powers (up to sign). Of course we could have derived this also from the well-known duality $h^{p,q} = h^{n-p,n-q}$:

$$\chi^p = \sum_{q=0}^n (-1)^q h^{p,q} = (-1)^n \sum_{q=0}^n (-1)^{n-q} h^{n-p,n-q}$$

$$= (-1)^n \chi^{n-p}. $$

Example: The circle $S^1$ acts on $P_2(\mathbb{C})$ by

$$(z_0 : z_1 : z_2) \mapsto (z_0 : q \cdot z_1 : q^2 \cdot z_2).$$

This action has three fixed points, namely

$$P_0 = (1 : 0 : 0), \ P_1 = (0 : 1 : 0), \ P_2 = (0 : 0 : 1).$$
5.8 The equivariant signature for $S^1$-actions

In affine coordinates $S^1$ acts at

- $P_0$ by $(z_1, z_2) \mapsto (q \cdot z_1, q^2 \cdot z_2)$
- $P_1$ by $(z_0, z_2) \mapsto (q^{-1} \cdot z_0, q \cdot z_2)$
- $P_2$ by $(z_0, z_1) \mapsto (q^{-2} \cdot z_0, q^{-1} \cdot z_1)$.

Hence we have

$$
\chi_y(P_0(C)) = \chi_y(id, P_2(C))
= \chi_y(P_2)(-y)^2 + \chi_y(P_1)(-y) + \chi_y(P_0)
= \chi_y(P_2) + \chi_y(P_1)(-y) + \chi_y(P_0)(-y)^2
= y^2 - y + 1.
$$

In the same way one obtains for $P_n(C)$ the formula

$$
\chi_y(P_n(C)) = \sum_{i=0}^{n} (-y)^i,
$$

which we could also obtain from consideration of the Dolbeault complex.

5.8 The equivariant signature for $S^1$-actions

We can only define the $\chi_y$-genus for complex manifolds. But for several values of $y$ it is already defined for differentiable manifolds. These are for $y = -1$ the Euler number (not a genus) and for $y = 1$ the signature. For the Euler number we have already seen that its equivariant analog is simply the sum of the Euler numbers of the fixed components. This also holds for differentiable manifolds. What happens for the signature?

Now let $X$ be a $2n$-dimensional compact, oriented, differentiable manifold (up to now we have only considered the signature for even $n$). If we want to apply the equivariant Atiyah-Singer index theorem, we must again consider the decomposition of the bundle $TX|_{X^*_q}$ with respect to the action of a topological generator $q$ of $S^1$. The irreducible representations of $S^1$ on real vector spaces are obtained from the complex representations by identification of $\mathbb{R}^2$ with $\mathbb{C}$. The multiplication with $q^k$ then corresponds to a rotation in $\mathbb{R}^2$ through the $k$-fold angle of $q$. By suitable identification one can always take $k \geq 0$. We therefore obtain a splitting

$$
TX|_{X^*_q} = \sum_{k \geq 0} q^k N_k = TX_{S^1} \oplus \sum_{k \geq 0} q^k N_k.
$$
The bundles $N_k$ are real bundles, which for $k > 0$ obtain a complex structure through the identification with a complex bundle. This identification yields a unique orientation on $N_k$, in view of the condition $k > 0$. Since the fixed component $X^S^1$ is orientable, $N_0 = TX^S^1$ can now be oriented so that all orientations taken together yield the orientation of $X$. In particular, according to this rule $X^S^1$ must sometimes be counted negatively when it is a point.

Having made this splitting, the equivariant index theorem yields:

$$\text{sign}(q, X) = \sum_{\nu} a(X^S^1),$$

$$a(X^S^1) = \left(\prod_{i=1}^{d_0} x_i^{(1)} \frac{1 + e^{-a_i^{(1)}}}{1 - e^{-a_i^{(1)}}}, \left(\prod_{k>0} \prod_{i=1}^{d_k} \frac{1 + q^k e^{-a_i^{(k)}}}{1 - q^k e^{-a_i^{(k)}}}\right)\right)[X^S^1].$$

Since the equivariant signature $\text{sign}(q, X)$ does not depend on $q$ ($S^1$ is connected, so acts trivially on cohomology), we can put $q = 0$ and have

$$a(X^S^1) = \left(\prod_{i=1}^{d_0} x_i^{(1)} \frac{1 + e^{-a_i^{(1)}}}{1 - e^{-a_i^{(1)}}}\right)[X^S^1] = \left(\prod_{i=1}^{d_0} x_i^{(1)} e^{a_i^{(1)}/2} + e^{-a_i^{(1)}/2}\right)[X^S^1] = \left(\prod_{i=1}^{d_0} x_i^{(1)} \frac{2}{\tanh(x_i^{(1)}/2)}\right)[X^S^1] = \text{sign}(X^S^1).$$

The next to last equation is obtained by replacing $x_i^{(1)}$ by $2x_i^{(1)}$ and correcting the error by division by $2^{d_0}$.

We again assume that $S^1$ acts with isolated fixed points. Then the signature is

$$\text{sign}(X) = \text{sign}(q, X) = \sum_{\nu} \pm \prod_{k>0} \prod_{i=1}^{d_k^{(\nu)}} \frac{1 + q^k}{1 - q^k} = \sum_{\nu} (\pm 1).$$

The last equation holds again, since we know that the sum does not depend on $q$ and we can therefore put $q = 0$. Here a fixed point receives the sign plus if $T_pX = \bigoplus_{k>0} N_k$ holds with the correct orientation, otherwise the sign minus.

**Example:** The circle $S^1$ acts on $S^{2n} \subset \mathbb{C}^n \times \mathbb{R}$ (coordinates $(z_1, \ldots, z_n, x)$) by rotation around the axis through the poles ($z_j \mapsto q \cdot z_j$ for $q \in S^1$ and $1 \leq j \leq n$). The fixed points are the north and south poles. The Euler number is $1 + 1 = 2$ and the signature is $1 - 1 = 0$ (the direction of rotation is once compatible with the orientation and once not).
6 Twisted operators and genera

6.1 Motivation for elliptic genera after Ed Witten

Let $X$ again be a compact, oriented and differentiable manifold of dimension $4k$. The free loop space of $X$ is the infinite dimensional manifold

$$\mathcal{L}X = \{ g : S^1 \to X \mid g \text{ differentiable} \}.$$ 

There is a canonical action of the circle $S^1 \cong \mathbb{R}/\mathbb{Z}$ on $\mathcal{L}X$. If $g \in \mathcal{L}X$ is a loop, i.e. $g(x) \in X$ for $x \in S^1$, then the action of $t \in S^1$ on $g$ is defined by $t(g)(x) := g(x - t)$. The fixed point set $(\mathcal{L}X)^{S^1}$ under this action is the manifold $X$ itself, considered as the submanifold of constant loops in $\mathcal{L}X$. The tangent space at a loop $g \in \mathcal{L}X$ is $T_g(\mathcal{L}X) \cong \Gamma(g^*(TX))$, where as usual $\Gamma$ denotes the sections of a bundle. For a constant loop $g \equiv p \in X$ the bundle $g^*(TX)$ is isomorphic to $S^1 \times T_pX$, so that

$$T_p(\mathcal{L}X) \cong \Gamma(S^1 \times T_pX) = \mathcal{L}(T_pX).$$

This decomposes into eigenspaces with respect to the $S^1$-action. Since $s \in \mathcal{L}(T_pX)$ is a mapping of $\mathbb{R}/\mathbb{Z}$ into a vector space $V$, $s$ has a Fourier expansion:

$$s(x) = \frac{a_0}{2} + \sum_{n > 0} (a_n \cos(2\pi nx) + b_n \sin(2\pi nx)) \in \mathcal{L}(T_pX).$$

Here the coefficients $a_n, b_n$ are elements of $T_pX$. The circle $S^1 \cong \mathbb{R}/\mathbb{Z}$ acts as follows:

$$t(s)(x) = \frac{a_0}{2} + \sum_{n > 0} (a_n \cos(2\pi n(x - t)) + b_n \sin(2\pi n(x - t))) \in \mathcal{L}(T_pX).$$

Moreover, we have

$$a_n \cos(2\pi n(x - t)) + b_n \sin(2\pi n(x - t))$$

$$= a_n \cos(2\pi nx) \cdot \cos(2\pi nt) + b_n \sin(2\pi nx) \cdot \sin(2\pi nt)$$

$$+ b_n \sin(2\pi nx) \cdot \cos(2\pi nt) - b_n \cos(2\pi nx) \cdot \sin(2\pi nt)$$

$$= \tilde{a}_n \cos(2\pi nx) + \tilde{b}_n \sin(2\pi nx).$$
where
\[ a_n + i b_n = (a_n + i b_n) \cdot e^{2 \pi i t} = (a_n + i b_n)q^n \in T_p X \otimes \mathbb{C} \]
with \( q = e^{2 \pi i t} \). We shall denote the bundle \( TX \otimes \mathbb{C} \) by \( T_c \). Hence we have verified that
\[ T(LX)|_X = TX \oplus \sum_{n>0} q^n T_c. \]

So we have bundles of finite rank, but infinitely many of them. It is probably possible to define directly an equivariant signature \( \text{sign}(q, LX) \), under certain assumptions (such as orientability of the loop space). We shall achieve this indirectly: we apply the Atiyah-Singer index theorem and define the result to be the equivariant signature. With
\[ p(X) = 1 + p_1 + \cdots + p_h = (1 + x_1^2) \cdots (1 + x_{2k}^2), \]
\[ c(T_c) = (1 + x_1) \cdots (1 + x_{2k})(1 - x_1) \cdots (1 - x_{2k}), \]
our recipe in section 5.8 applied to the loop space gives the

**Definition:** The equivariant signature of the loop space is
\[ \text{sign}(q, LX) := \prod_{i=1}^{2k} \left( \frac{1 + e^{-z_i}}{1 - e^{-z_i}} \cdot \prod_{n=1}^{\infty} \left( \frac{(1 + q^n e^{-z_i})(1 + q^n e^{z_i})}{(1 - q^n e^{-z_i})(1 - q^n e^{z_i})} \right) \right)[X]. \]

This power series is symmetric in the \( x_i^2 \), and after evaluation on \( X \) is a power series in \( q \) with rational coefficients.

**Definition:** Let \( X \) be a differentiable manifold of dimension \( 2k \) and \( W \) a complex vector bundle over \( X \). Then the signature of \( X \) with values in the vector bundle \( W \) is defined as
\[ \text{sign}(X, W) := \left( \prod_{i=1}^{k} \frac{x_i \cdot (1 + e^{-z_i})}{1 - e^{-z_i}} \cdot \text{ch}(W) \right)[X]. \]

**Remark:** This is the index of an elliptic operator, from which follows the integrality of \( \text{sign}(X, W) \): Recall the signature operator \( d + d^* : \Gamma E_+ \rightarrow \Gamma E_- \), with the eigenspace bundles \( E_+ = (\Lambda^* T \otimes \mathbb{C})^+ \) and \( E_- = (\Lambda^* T \otimes \mathbb{C})^- \) of the Hodge \(*\)-operator (on \( \Lambda^* T \otimes \mathbb{C} \)). By means of a connection on \( W \), the signature operator can be extended to a twisted operator \( \Gamma(E_+ \otimes W) \rightarrow \Gamma(E_- \otimes W) \) whose index is \( \text{sign}(X, W) \) (cf. [Pa65], IV, §9).

In order that the power series under the product begin with 1 (stable notation), we replace \( x_i \) by \( 2x_i \) and correct the error by dividing the factors by 2. If \( W \) has rank \( r \), total Chern class \( c(W) = (1 + y_1) \cdots (1 + y_r) \) and Chern character \( \text{ch}(W) = e^{y_1} + \cdots + e^{y_r} \),
then the passage from $y_j$ to $2y_j$ corresponds to the topological construction of a bundle $\Psi_2(W)$ (Adams operation), i.e. we have

$$\text{ch}(\Psi_2(W)) = e^{2y_1} + \cdots + e^{2y_r}.$$ 

Hence

$$\text{sign}(X, W) = \left( \prod_{i=1}^{k} \frac{x_i}{\tanh(x_i)} \text{ch}(\Psi_2(W)) \right)[X]$$

is stable and integral, and the first factor yields the $L$-class of the tangent bundle. All powers of two in the coefficients of the exponential function are canceled by the replacement of $y$ with $2y$. The Adams operation therefore yields the vanishing of the powers of two in the denominator of the twisted signature; the absence of the other primes in the denominator remains an interesting matter.

**Example:** For $X$ a sphere $S^{2k}$ and an arbitrary vector bundle $W$ over $S^{2k}$ we have

$$\text{sign}(S^{2k}, W) = \text{ch}(\Psi_2(W))[S^{2k}] \in \mathbb{Z},$$

since $p(S^{2k}) = 1$. Further,

$$\text{ch}(\Psi_2(W))[S^{2k}] = \left( \sum_{i=1}^{r} \frac{(2y_i)^k}{k!} \right)[S^{2k}].$$

This sum can be expressed in the Chern classes of $W$. Since the cohomology of the sphere vanishes away from dimension $2k$, it suffices to compute the contribution of $c_k(W)$. This is (consider the multiplicative sequence for $Q(x) = 1 + x^k$ and the Cauchy lemma in section 1.8)

$$\left( \sum_{i=1}^{r} \frac{(2y_i)^k}{k!} \right)[S^{2k}] = (-1)^{k+1} \frac{2^k \cdot k}{k!} c_k(W)[S^{2k}].$$

Hence for each vector bundle $W$ over $S^{2k}$

$$2^k \cdot c_k(W) \equiv 0 \ ((k - 1)!).$$

At the end of section 6.2 we shall see that even $c_k(W) \equiv 0 \ ((k - 1)!) \text{ holds.}$

Making use of the previous definitions $\Lambda_iT = \sum_{i=0}^{\infty} \Lambda^iT \cdot t^i$ and $S_iT = \sum_{i=0}^{\infty} S^iT \cdot t^i$, we now represent the equivariant signature of the loop space of a $4k$-dimensional manifold as an expression in twisted signatures:

**Theorem:** We have

$$\text{sign}(q, LX) = \text{sign}(X, \bigotimes_{n=1}^{\infty} S_{q^n}T_C \otimes \bigotimes_{n=1}^{\infty} \Lambda_{q^n}T_C).$$

Therefore $\text{sign}(q, LX)$ is a power series in $q$ with integral coefficients and constant term (coefficient of $q^0$) $\text{sign}(X)$. 

---

**6.1 Motivation for elliptic genera after Ed Witten**

75
Proof: It must be shown that
\[
\text{ch} \left( \bigotimes_{n=1}^{\infty} S_n^* T_C \otimes \bigotimes_{n=1}^{\infty} \Lambda_n^* T_C \right) = \prod_{i=1}^{2k} \prod_{n=1}^{\infty} \frac{(1 + q^n e^{-\pi i}) (1 + q^n e^{\pi i})}{(1 - q^n e^{-\pi i})(1 - q^n e^{\pi i})}.
\]
However this is clear from the definitions of the bundles and the formulas for the Chern characters given in section 1.5.

Remark: It is well-known that a product \( \prod (1 + u_i) \) converges absolutely provided that the series \( \sum |u_i| \) converges, hence in our case only for \( |q| < 1 \). We have therefore only defined an equivariant signature formally, but it is meaningful as a power series.

We now consider the connection with elliptic genera: The constant term in the (not yet evaluated) expression for \( \text{sign} (q, \mathcal{L}X) \) is
\[
(2 \cdot \prod_{n=1}^{\infty} \frac{(1 + q^n)^2}{(1 - q^n)^2})^{2k};
\]
we have therefore not formulated the expression stably. But \( \text{sign} (X, \mathcal{L}X) \) is, up to this normalization factor, the genus associated to
\[
\frac{x}{f(x)} = \frac{1}{2 \tanh (x/2)} \cdot \prod_{n=1}^{\infty} \frac{(1 + q^n e^x)(1 + q^n e^{-x})}{(1 - q^n e^x)(1 - q^n e^{-x})} \cdot \frac{(1 + q^n)^2}{(1 - q^n)^2}.
\]
As discussed in Appendix I, Theorem 5.6, this is precisely the expansion of \( x \sqrt{\wp(x) - \sigma_1} \), where \( q = e^{2\pi i \tau} \) and \( \wp \) is the Weierstraß \( \wp \)-function for the lattice \( L = 2\pi i (\mathbb{Z} \tau + \mathbb{Z}) \) as described in section 2.1. We therefore immediately deduce the

Corollary: We have
\[
\text{sign} (q, \mathcal{L}X) = \wp(X) \cdot q^{2k} \left( \prod_{n=1}^{\infty} \frac{(1 + q^n)^2}{(1 - q^n)^2} \right)^{2k}.
\]
Here \( \wp(X) \) is the elliptic genus of \( X \), hence a modular form of weight \( 2k \) on \( \Gamma_0(2) \) as described in Appendix I. We now investigate whether the correction factor is also a modular form. For the following, cf. Appendix I, §4: The Dedekind \( \eta \)-function is defined as
\[
\eta(\tau) = q^{1/24} \prod_{n=1}^{\infty} (1 - q^n)
\]
and is holomorphic in the upper half-plane \( \mathbb{H} \). Further, \( \eta^{24} = \Delta \) is an element of weight 12 in \( \mathcal{M}_* \text{cusp}(\Gamma) \), the ring of cusp forms on the modular group \( \Gamma = \text{SL}_2(\mathbb{Z}) \). Hence \( \eta \)
is a “modular form” of weight 1/2 (the quotation marks being due to a problem with 24-th roots of unity).

**Lemma:** The infinite product

\[
\left( 2 \prod_{n=1}^{\infty} \frac{(1+q^n)^2}{(1-q^n)^3} \right)^{-4}
\]

is a modular form of weight 4 on \( \Gamma_0(2) \), and is indeed precisely our modular form \( \epsilon \).

**Proof:** We have

\[
\prod_{n=1}^{\infty} \frac{(1-q^n)^2}{(1+q^n)^3} = \prod_{n=1}^{\infty} \frac{(1-q^n)^4}{(1-q^{2n})^3} = \frac{\eta(\tau)^4}{\eta(2\tau)^3}.
\]

The rest follows from Appendix I, Corollary 4.11.

The reciprocal of the correction factor has the same weight \( 2k \) as the modular form \( \varphi(X) \), but is only a modular form when \( 2k \equiv 0 \) (4). We therefore have the

**Theorem:** The equivariant signature is \( \text{sign} (q, L^X) = \varphi(X) \cdot \epsilon^{-k/2} \), and is a modular function on \( \Gamma_0(2) \) for \( \dim X = 4k \equiv 0 \) (8).

**Remark:** By considering \( X \times X \) if \( \dim X \equiv 4 \) (8) it follows that in every case \( \text{sign} (q, L^X)^2 \) is a modular function on \( \Gamma_0(2) \).

**Example:** Since \( \varphi(P_2(\mathbb{C})) = \delta \), it follows that \( \text{sign} (q, L^2(\mathbb{C}))^2 = \delta^2 / \epsilon \).

**Corollary:** For the quaternionic projective spaces we have:

\[
\text{sign} (q, L^P(\mathbb{H})) = \begin{cases} 0, & \text{for } k \equiv 1 \pmod{2}, \\ 1, & \text{for } k \equiv 0 \pmod{2}. \end{cases}
\]

For the Milnor manifolds \( H_{ij} \) we have (taking \( j \geq i \) as we may):

\[
\text{sign} (q, L^{H_{ij}}) = \begin{cases} 0, & \text{for } i \equiv 1 \pmod{2} \text{ or } i \equiv j \pmod{2}, \\ 1, & \text{for } i \equiv 0 \pmod{2} \text{ and } j = i + 1. \end{cases}
\]

In particular, for these manifolds the considered twisted signatures vanish (apart from \( \text{sign} (1, X) = \text{sign} (X) \)).

**Proof:** Compare sections 1.7 and 3.2.

---

**6.2 The expansion at the cusp 0**

Let a lattice \( L \subset \mathbb{C} \) be given and let \( h(x) = x^2 + \cdots \) be an elliptic function with divisor \( 2 \cdot (0) - 2 \cdot (P) \) (then \( P \) must automatically be a two-division point of \( L \)).
then \( f(x) = \sqrt{h(x)} \) with the normalization \( f(x) = x + \cdots \) defines an unbranched two-sheeted covering \( \mathbb{C}/\tilde{L} \to \mathbb{C}/L \). Here \( \tilde{L} \subset L \) is a sublattice of index two with respect to which \( f \) is elliptic. Since \( P = -P(L) \) we have \( \text{div}(h(x)) = \text{div}(h(-x)) \), so \( h(x) \) and \( h(-x) \) coincide up to a constant factor. Because \( h(x) = x^2 + \cdots \), this factor is 1 and \( h \) is an even function. Since \( f(x) = \sqrt{h(x)} = x + \cdots \), \( f \) is odd and therefore \( Q(x) = x/f(x) = 1 + \cdots \) is an even power series, which we can take as the characteristic power series for a genus.

This power series depends on the lattice \( (L, P) \) with distinguished two-division point. If \( f \) belongs to \( (L, P) \), then \( f(\lambda x)/\lambda \) belongs to the lattice \( (\frac{1}{2}L, \frac{1}{2}P) \). Hence the coefficients \( a_k \) of \( Q(x) \) in the power series expansion \( Q(x) = \sum_{k=0}^{\infty} a_k x^k \) are lattice functions of weight \(-k\) for marked lattices. We shall now consider only lattices of the form \( 2\pi i(\mathbb{Z}\tau + \mathbb{Z}) \). The passage from lattices \( \mathbb{Z}\omega_2 + \mathbb{Z}\omega_1 \) to these special lattices corresponds exactly to the passage from homogeneous lattice functions to modular forms. We thereby lose (up to a stretching factor) no information, since \( \mathbb{Z}\omega_2 + \mathbb{Z}\omega_1 = \frac{\omega_1}{2\pi i} \cdot 2\pi i(\mathbb{Z}\omega_2 + \mathbb{Z}) \). In addition we suppose that \( \tau \) lies in \( \mathfrak{h} = \{ z \in \mathbb{C} \mid \text{Im}(z) > 0 \} \), which we can always attain by permuting \( \omega_2 \) and \( \omega_1 \).

In our construction of the elliptic genus, for a lattice \( L = 2\pi i(\mathbb{Z}\tau + \mathbb{Z}) \) we take the point \( P = \pi i \) and \( h(x) = (p(x) - e_1)^{-1} \); the function \( f(x) = (p(x) - e_1)^{-1/2} \) is elliptic for the lattice \( 2\pi i(\mathbb{Z} \cdot 2\tau + \mathbb{Z}) \). We then obtain the Fourier expansion (cf. Appendix I, §5):

\[
Q(x) = \frac{x}{f(x)} = \frac{1}{2} \frac{x}{\tanh(x/2)} \prod_{n=1}^{\infty} \frac{(1 + q^n e^x)(1 + q^n e^{-x})}{(1 + q^n)^2}.
\]

For this choice of two-division point the passage from lattice functions to modular forms yields precisely modular forms on the congruence subgroup

\[
\Gamma_0(2) = \{ (a \ b) \ c \ d \in \text{SL}_2(\mathbb{Z}) \mid c \equiv 0 \ (2) \}
\]

(cf. Appendix I, §4 and notice that \( \Gamma_1(2) = \Gamma_0(2) \)). Applied to a pair of basis vectors \( (\omega_2, \omega_1) \) of a lattice, for such a matrix we have

\[
\begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} \omega_2 \\ \omega_1 \end{pmatrix} = \begin{pmatrix} a\omega_2 + b\omega_1 \\ c\omega_2 + d\omega_1 \end{pmatrix}
\]

and the two-division point \( \omega_1/2 \) goes to the point \((c\omega_2 + d\omega_1)/2\), which is always equivalent to \( \omega_1/2 \) modulo \( L \) (since \( c \) is even and \( d \) must be odd due to the determinant condition).

If we take \( f(x) = (p(x) - e_2)^{-1/2} \) in the construction of our elliptic genus, then we obtain (the product runs over all \( m \geq 0 \)):

\[
\frac{x}{f(x)} = \frac{x/2}{\sinh(x/2)} \prod_{n=2m+1}^{\infty} \frac{(1 - q^n/2 e^x)(1 - q^n/2 e^{-x})}{(1 - q^n/2)^2}.
\]
The shift of indices under the translations $x \mapsto x + 2\pi i\tau$ and $x \mapsto x + 2\pi i$ (for which the sign changes) shows, that this function $f$ is elliptic for the lattice $2\pi i(Z\tau + Z \cdot 2)$. Furthermore an analysis of the zeroes and poles shows that it has the demanded divisor. In addition the normalization is correct. The congruence subgroup $\Gamma_0(2)$ has two cusps, which can be represented by $\infty = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$ and $0 = \begin{pmatrix} 0 \\ 1 \end{pmatrix}$. Modular forms $F$ on this group must have a Fourier expansion without negative exponents at each of these cusps. At the cusp $0$, one obtains this expansion by means of a matrix $A \in SL_2(Z)$ with $A \begin{pmatrix} 1 \\ 0 \end{pmatrix} = \begin{pmatrix} 0 \\ 1 \end{pmatrix}$ (say $A = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$), through the Fourier expansion of $F|_{k}A$ at the cusp $\infty$. This new modular form is now invariant under the action of

\[ A^{-1}\Gamma_0(2)A = \Gamma^0(2) = \{(a \ b; c \ d) \in SL_2(Z) \mid b \equiv 0 \ (2)\}. \]

Notice that $\Gamma_0(2)$ and $\Gamma^0(2)$ are not normal subgroups of $\Gamma(1) = SL_2(Z)$, since they are conjugate and do not coincide. Both have index 3 in $\Gamma(1)$. The matrices $S = \begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix}$ ($\tau \mapsto -1/\tau$) and $T = \begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix}$ ($\tau \mapsto \tau + 1$) generate $\Gamma(1)$. In the following figure, fundamental domains for $\Gamma_0(2)$ (parts labelled $Id, S, ST$) and $\Gamma^0(2)$ (parts labelled $Id, S, T$) are indicated, which we shall take as standard fundamental domains. Both have two cusps, 0 and $\infty$, which are exchanged by $\tau \mapsto -1/\tau$.

Now our exchange of two-division points corresponds exactly to an exchange of the cusps (see Appendix I, Theorem 6.4). Only powers of $q^{1/2}$ enter into our expansion of $f(x)$, since $\begin{pmatrix} 1 & 2 \\ 0 & 1 \end{pmatrix} \in A^{-1}\Gamma_0(2)A = \Gamma^0(2)$, so $f|_{k}A$ is invariant under $\tau \mapsto \tau + 2$. The coefficients $a_k$ of the Taylor expansion of $x/f(x)$ are therefore modular forms of weight $k$ on $\Gamma^0(2)$ and have a Fourier expansion in $q^{1/2}$ at the cusp $\infty$. Since we shall later compare the elliptic genera for different two-division points with one another, we attempt to return to $\Gamma_0(2)$ by a further conjugation, which leaves the Fourier expansion

Some fundamental domains on the upper half-plane
essentially unchanged. The groups $\Gamma^0(2)$ and $\Gamma_0(2)$ are carried into one another by conjugation with the matrix \(
abla \begin{pmatrix} 2 & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} 2 & 0 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} a & \frac{b}{2} \\ 2c & d \end{pmatrix} \in \Gamma_0(2)\)

if \(b\) is even. This corresponds to the passage from \(\tau\) to \(2\tau\), hence from \(q\) to \(q^2\). Our expression above therefore becomes

\[ \frac{x/2}{\sinh (x/2)} \prod_{n=1}^{\infty} \left( \frac{1-q^n e^x}{1-q^n} \right)^{(-1)^{n-1}} \]

which is elliptic in \(x\) (after division by \(x\)) for the lattice \(4\pi i(\mathbb{Z}\tau + \mathbb{Z})\) and has coefficients which are modular forms on \(\Gamma_0(2)\).

**Exercise:** What happens for the third two-division point, i.e.

\[ f(x) = \frac{1}{\sqrt{p(x) - e_3}} \]

For \(f(x) = (p(x) - e_2)^{-1/2}\) we have obtained (product over \(m \geq 0\))

\[ \frac{x}{f(x)} = \frac{x/2}{\sinh (x/2)} \prod_{n=2m+1} \prod_{n=2m+2} \frac{(1-q^{n/2} e^x)(1-q^{n/2} e^{-x})}{(1-q^n)^2} \frac{1-q^{n/2} e^{-x}}{1-q^{n/2}} \]

The corresponding genus for a manifold \(X^{4k}\) is then a modular form of weight \(2k\) on \(\Gamma^0(2)\), whose Fourier expansion is that of the usual genus \(g\) for \(f(x) = (p(x) - e_1)^{-1/2}\) at the cusp 0. If we replace \(\tau\) by \(2\tau\), we obtain a genus \(\bar{g}\) which again yields modular forms on \(\Gamma_0(2)\):

\[ \bar{g}(X) = \left( \prod_{i=1}^{2k} \frac{x_i/2}{\sinh (x_i/2)} \prod_{n=1}^{\infty} \left( \frac{1-q^{n} e^{x_i}}{1-q^{n}} \right)^{(-1)^{n-1}} \right)[X]. \]

We consider the normalization factor (product over \(m \geq 0\)):

\[ \prod_{n=2m+1}^{2m+2} \frac{(1-q^n)^2}{(1-q^n)^2} = \prod_{n=2m+1}^{\infty} \frac{(1-q^n)^4}{(1-q^n)^2} = \prod_{n=1}^{\infty} \frac{(1-q^{2n})^4}{(1-q^{n})^2} = q^{-1/4} \frac{\eta(2\tau)^4}{\eta(\tau)^2}. \]
6.2 The expansion at the cusp $0$

Here $q$ is $q^{1/24} \cdot \prod_{n=1}^{\infty} (1 - q^n)$ and $\eta^{24} = q \cdot \prod_{n=1}^{\infty} (1 - q^n)^{24} = \Delta$ is again a cusp form of weight 12 on the full modular group. For a manifold of dimension $4k$ the normalization factor is

$$q^{-k/2} \left( \frac{\eta(2\tau)^4}{\eta(\tau)^2} \right)^{2k};$$

the expression inside the parentheses is a modular form of weight one, up to an indeterminacy in fourth roots of unity, since we have (cf. Appendix I, Corollary 4.11)

$$\left( \frac{\eta(2\tau)^4}{\eta(\tau)^2} \right)^4 = \tilde{\varepsilon} = \frac{\delta^2 - \varepsilon}{4} \in M_k(\Gamma_0(2)).$$

For $k$ even, if one divides our expression for the genus by the modular form $\tilde{\varepsilon}^{k/2}$, the resulting quotient of two modular forms of weight $2k$ is the modular function

$$q^{-k/2} \cdot \left( \prod_{i=1}^{2k} \frac{x_i/2}{\sinh(x_i/2)} \prod_{n=1}^{\infty} ((1 - q^n e^{x_i})(1 - q^n e^{-x_i}))^{(-1)^{n-1}} \right) [X].$$

We now return to the $\hat{A}$-genus:

$$\hat{A}(X) = \left( \prod_{i=1}^{2k} \frac{x_i/2}{\sinh(x_i/2)} \right) [X].$$

**Definition:** Let $X$ be a differentiable manifold of dimension $2k$ and $W$ a complex vector bundle over $X$. Then the twisted $\hat{A}$-genus $\hat{A}(X, W)$ is defined as

$$\hat{A}(X, W) := (\text{ch} \,(W) \cdot \hat{A}(TX))[X]$$

$$= (\text{ch} \,(W) \cdot \prod_{i=1}^{k} \frac{x_i/2}{\sinh(x_i/2)}) [X].$$

**Remark:** For a spin manifold $X$, $\hat{A}(X, W)$ is the index of a twisted Dirac operator and so is integral (cf. Appendix II).

**Example:** Let $X = S^{2k}$ be a sphere (so spin) and $W$ a vector bundle over $S^{2k}$. Then

$$\hat{A}(S^{2k}, W) = (\hat{A}(TS^{2k}) \cdot \text{ch} \,(W)) [S^{2k}] = \text{ch} \,(W)[S^{2k}],$$

since $\hat{A}(TS^{2k}) = 1$ (spheres have stably trivial tangent bundles). As in section 6.1 it now follows that

$$\hat{A}(S^{2k}, W) = \frac{(-1)^{k+1}}{(k-1)!} c_k(W)[S^{2k}] \in \mathbb{Z},$$
so that we indeed obtain

\[ c_k(W) \equiv 0 \ (k - 1)! . \]

In our expression above (product over \( m \geq 0 \))

\[
q^{-k/2} \left( \prod_{i=1}^{2k} \frac{x_i/2}{\sinh (x_i/2)} \right) \prod_{n=2m+1}^{\infty} \left( 1 - q^n e^{x_i} \right) \left( 1 - q^n e^{-x_i} \right) [X],
\]

we can recognize with a practiced eye that we are dealing with a twisted \( \hat{A} \)-genus, namely with

\[
\frac{\varphi(X)}{e^{k/2}} = q^{-k/2} \cdot \hat{A} \left( X, \bigotimes_{n=2m+1}^{\infty} \Lambda_{q^n T\mathbb{C}} \otimes \bigotimes_{n=2m+2}^{\infty} S_{q^n T\mathbb{C}} \right).
\]

However, there is so far no interpretation for this expression as the index of an operator on the loop space. Its meaning for us is simply the expansion at the other cusp of the equivariant signature of the loop space

\[
\varphi(X) = \text{sign} \left( X, \bigotimes_{n=1}^{\infty} S_{q^n T\mathbb{C}} \otimes \bigotimes_{n=1}^{\infty} \Lambda_{q^n T\mathbb{C}} \right) = \text{sign} \left( q, \mathcal{L}X \right).
\]

### 6.3 The Witten genus

Let \( L \subset \mathbb{C} \) be a lattice, and let

\[
\sigma_L(x) = x \cdot \prod_{\omega \in L \setminus \{0\}} \left( (1 - \frac{x}{\omega}) \cdot \exp \left( \frac{x}{\omega} + \frac{x^2}{2\omega^2} \right) \right)
\]

for \( x \in \mathbb{C} \) be the Weierstraß \( \sigma \)-function for the lattice \( L \). The infinite product converges uniformly on compact sets, due to the exponential convergence factors. These convergence factors are determined by logarithmically differentiating \( (1 - \frac{x}{\omega}) \):

\[
\left( \frac{1 - \frac{x}{\omega}}{1 - \frac{x}{\omega}} \right)^\prime = \frac{-x}{1 - \frac{x}{\omega}} \equiv -\frac{1}{\omega} \left( 1 + \frac{x}{\omega} \right) \equiv -\left( \frac{1}{\omega} + \frac{x}{\omega^2} \right) (x^2).
\]

The function \( \sigma_L(x) \) is odd, so that the power series \( Q(x) = x/\sigma_L(x) = 1 + a_2 x^2 + a_4 x^4 + \cdots \) is even. For this we have

\[
\frac{\lambda x}{\sigma_L(\lambda x)} = \frac{x}{\sigma_L(x)},
\]
6.3 The Witten genus

i.e. the coefficients \( a_r \) of \( x^r \) are multiplied by \( \lambda^r \) if the lattice is divided by \( \lambda \). They are therefore homogeneous lattice functions of weight \(-r\), and so modular forms with respect to \( L = 2\pi i(2\pi + Z)\) of weight \( r \) on the full modular group \( SL_2(Z) \) (one must still argue that the \( a_r \) are holomorphic and determine the form of their Fourier expansions at the cusp \( \infty \)). Since there are no modular forms of weight 2, we have \( a_2 = 0 \).

This power series \( Q(x) \) has a beautiful logarithm. Before giving this, we recall some important modular forms (cf. Appendix I, §3 and section 2.1; as usual, \( q = e^{2\pi i \tau} \)):

\[
E_{2k}(\tau) = 1 + \frac{4k}{-B_{2k}} \cdot \sum_{n=1}^{\infty} \sigma_{2k-1}(n) \cdot q^n,
\]

\[
G_{2k}(\tau) = \frac{-B_{2k}}{4k} \cdot E_{2k} = \frac{-B_{2k}}{4k} + \sum_{n=1}^{\infty} \sigma_{2k-1}(n) \cdot q^n
\]

\[
= \frac{(2k-1)!}{2} \cdot \sum_{\omega \in L'} \frac{1}{\omega^{2k}} = \frac{(2k-1)!}{2} \cdot s_{2k}.
\]

Here \( L' = L \setminus \{0\} \). For \( k > 1 \), these are modular forms on the full modular group; \( G_2 \) (and so of course \( E_2 \)) also converges,

\[
G_2 = \frac{-B_2}{4} + \sum_{n=1}^{\infty} \sigma_1(n) \cdot q^n = -\frac{1}{24} + q + 3q^2 + \cdots.
\]

We now have (cf. Appendix I, §5):

\[
Q(x) = \exp \left( \sum_{k=2}^{2k} \frac{2}{(2k)!} G_{2k}(\tau) \cdot x^{2k} \right).
\]

As we have seen in section 1.8, the genera of complex manifolds for which all Chern classes apart from the highest vanish can be given precisely in terms of the logarithm of the characteristic power series. In this way, the so-called Witten genus \( \varphi_w \) associated to the characteristic power series \( Q(x) = x/\sigma_L(x) \) yields Eisenstein series for such manifolds. The notation \( \varphi_w \) was proposed by Landweber, since the "W" reminds one of Weierstraß and/or Witten. For a compact, oriented, differentiable manifold \( X^{4k} \) we therefore have:

\[
\varphi_w(X) = \left( \prod_{i=1}^{2k} \frac{x_i}{\sigma_L(x_i)} \right)[X]
\]

is a modular form of weight \( 2k \).

**Proposition:** The power series \( Q(x) \) has the following product representation (cf. [Za86]):

\[
Q(x) = \frac{x/2}{\sinh(x/2)} \cdot \prod_{n=1}^{\infty} \frac{(1 - q^n)^2}{(1 - q^n e^x) \cdot (1 - q^n e^{-x})} e^{-G_2(\tau) \cdot x^2}.
\]
Idea of the proof: Consider the zeroes and poles of both sides, for fixed \( \tau \). The \( \sigma \)-function has simple zeroes at all lattice points, and no poles. The function \( \sinh(x/2) \) has zeroes at all multiples of \( 2\pi i \); the denominator vanishes if \( x \) modulo \( 2\pi i Z \) is a proper multiple of \( 2\pi i \tau \). Together, on both sides we have simple poles at all non-zero lattice points. The functions are of course not elliptic, but rather are theta functions with respect to the lattice \( L \). Therefore, they coincide a priori only up to a trivial theta function. The correct factor to yield equality is \( e^{-G_2(\tau)\cdot x^2} \) (cf. Appendix I, §5).

In the product representation of \( Q(x) \) some well-known terms appear, but the factor \( e^{-G_2(\tau)\cdot x^2} \) is troublesome. For this reason, in Appendix I, §5, we consider a function \( \Phi \) without this factor. Here we shall instead make the assumption that the first Pontrjagin class \( p_1(X) \) of our manifold \( X \) vanishes in \( H^4(X;\mathbb{Q}) \), so if \( p(X) = \prod_{i=1}^{2k} (1 + x_i^2) \) then \( p_1(X) = \sum_{i=1}^{2k} x_i^2 = 0 \), up to torsion. Then we obtain for the Witten genus:

\[
\varphi_w(X) = \left( \prod_{i=1}^{2k} \frac{x_i}{\sigma_L(x_i)} \right) [X]
\]

\[
= \left( \prod_{i=1}^{2k} \frac{x_i/2}{\sinh(x_i/2)} \cdot \prod_{n=1}^{\infty} \frac{(1-q^n)^3}{(1-q^n e^{x_i})(1-q^n e^{-x_i}) e^{-G_2(\tau)\cdot x_i^2}} \right) [X]
\]

\[
= \left( \prod_{i=1}^{2k} \frac{x_i/2}{\sinh(x_i/2)} \cdot \prod_{n=1}^{\infty} \frac{(1-q^n)^3}{(1-q^n e^{x_i})(1-q^n e^{-x_i})} e^{-G_2(\tau)\cdot \sum x_i^2} \right) [X]
\]

As in the last section, we now consider the \( \hat{A} \)-genus with coefficients in a vector bundle \( E \):

\[
\hat{A}(X, E) = \left( \prod_{i=1}^{2k} \frac{x_i/2}{\sinh(x_i/2)} \cdot \text{ch} (E) \right) [X].
\]

We recognize the denominator in the product expansion of the Witten genus from the section on representations. In terms of the previous notation \( S, E = \sum_{r=0}^{\infty} S^r E \cdot \tau^r \) we have (only for \( p_1(X) = 0 \! 1 \)):

\[
\varphi_w(X) = \hat{A}(X, \bigotimes_{n=1}^{\infty} S_q T_C) \cdot \prod_{n=1}^{\infty} (1-q^n)^{4k}.
\]

As always, \( T_C \) denotes the bundle \( TX \otimes \mathbb{C} \). We shall rewrite the product on the right side. For this we again use the famous cusp form

\[
\Delta = q \cdot \prod_{n=1}^{\infty} (1-q^n)^{24}
\]
of weight 12, whose coefficients are the Ramanujan numbers. We already know two modular forms of weight 12, namely \( E_4^2 \) and \( E_6^2 \). Both begin with constant term 1 and are integral (since the Bernoulli numbers \( B_4 \) and \( B_6 \) have a 1 in the numerator); hence \( E_4^2 - E_6^2 \) is a cusp form, and we have after normalization:

\[
\Delta = \frac{1}{1728} \cdot (E_4^3 - E_6^3).
\]

Here we have:

\[
E_4 = 1 + 240 \cdot q + 2160 \cdot q^2 + \cdots,
E_6 = 1 - 504 \cdot q - 16632 \cdot q^2 + \cdots.
\]

Despite the 1728, \( \Delta \) has an integral Fourier expansion, as we see from the product expansion above. We substitute \( \Delta \) into our expression for the Witten genus and so obtain:

\[
\varphi_W(X) = q^{-\frac{1}{12}} \cdot \hat{A}(X, \bigotimes_{n=1}^{\infty} S_{q^n} T_C) \cdot \Delta^{\frac{1}{12}}.
\]

As we have already seen, \( \varphi_W \) always yields a modular form; \( \Delta^{\frac{1}{12}} \) is a modular form for \( k \equiv 0 \pmod{6} \) and then

\[
q^{-\frac{1}{12}} \cdot \hat{A}(X, \bigotimes_{n=1}^{\infty} S_{q^n} T_C)
\]

becomes a modular function, otherwise we have difficulty with sixth roots of unity. The \( \hat{A} \)-genus is always integral up to powers of two in the denominator. For a spin manifold (this is equivalent to the vanishing of the second Stiefel-Whitney class) the \( \hat{A} \)-genus is the index of the Dirac operator and is therefore integral (cf. Appendix II). This also holds for the \( \hat{A} \)-genus with coefficients in suitable vector bundles (such as our \( \bigotimes_{n=1}^{\infty} S_{q^n} T_C \)). Since the Fourier expansion of \( q^{-\frac{1}{12}} \cdot \Delta^{\frac{1}{12}} = \prod_{n=1}^{\infty} (1 - q^n)^{4k} \) is also integral, we conclude the following

**Proposition:** For a 4k-dimensional compact, oriented, differentiable manifold \( X \) with \( p_1(X) = 0 \) and \( w_2(X) = 0 \), the Witten genus \( \varphi_W \) yields a modular form of weight 2k with integral Fourier expansion.

**Example:** Let \( X \) be as above, with \( \dim X = 24 \). The vector space of modular forms of weight 12 is spanned by \( E_4^2 \) and \( E_6^2 \), and so also by \( \Delta \) and \( E_4^2 - 744 \cdot \Delta \). The Witten genus \( \varphi_W(X) \) of \( X \) is therefore a linear combination of these two modular forms:

\[
\varphi_W(X) = \frac{1}{1728} \cdot \hat{A}(X, \bigotimes_{n=1}^{\infty} S_{q^n} T_C) \cdot \Delta
\]

\[
= a \cdot \Delta + b \cdot (E_4^2 - 744 \cdot \Delta).
\]
Why have we chosen precisely this basis?

There is the integral modular function

\[ j(\tau) := \frac{E_4^3}{\Delta} = 1 + 744 + 196884 \cdot q + \cdots, \]

i.e. \(j : \text{SL}_2(\mathbb{Z})\backslash \mathfrak{h} \to P_1(\mathbb{C})\). If we identify \(\text{SL}_2(\mathbb{Z})\backslash \mathfrak{h}\) with \(P_1(\mathbb{C})\), then \(j\) becomes a fractional linear transformation on \(P_1(\mathbb{C})\), which is determined by its values at three points. For the \(j\)-function we may take these to be \(j(i) = 1728\), \(j(e^{2\pi i/3}) = 0\), and \(j(\infty) = \infty\).

Dividing the above expression for \(\varphi_W(X)\) by \(\Delta\), we obtain:

\[
a + b \cdot (j - 744) = \frac{b}{q} + a + \cdots = q^{-1} \cdot \hat{A}(X, \bigotimes_{n=1}^{\infty} S_{q^n} T_{\mathbb{C}})
\]

\[
\Rightarrow a = \hat{A}(X, T_{\mathbb{C}}), \quad b = \hat{A}(X).
\]

For \(\hat{A}(X) \neq 0\) we now have the following formula:

\[
\frac{q^{-1} \cdot \hat{A}(X, \bigotimes_{n=1}^{\infty} S_{q^n} T_{\mathbb{C}})}{\hat{A}(X)} = \hat{A}(X, T_{\mathbb{C}}) + j - 744.
\]

The coefficients of \(j - 744\) are very interesting. Here are the first four:

\[j - 744 = q^{-1} + 196884 \cdot q + 21493760 \cdot q^2 + 864299970 \cdot q^3 + \cdots.\]

These coefficients are in fact special sums of the dimensions of the irreducible representations of the Monster (see below). This is the largest sporadic finite simple group.

We now come to the

**Prize Question:** Does there exist a 24-dimensional, compact, orientable, differentiable manifold \(X\) with \(p_1(X) = 0\), \(w_2(X) = 0\), \(\hat{A}(X) = 1\) and \(\hat{A}(X, T_{\mathbb{C}}) = 0\)?

Why are we interested in such a manifold? Under the above assumptions we have:

\[
j - 744 = q^{-1} \cdot \hat{A}(X, \bigotimes_{n=1}^{\infty} S_{q^n} T_{\mathbb{C}})
\]

\[
\equiv q^{-1} \cdot \hat{A}(X, (1 + q T_{\mathbb{C}} + q^2 S^2 T_{\mathbb{C}} + q^3 S^3 T_{\mathbb{C}}) (1 + q^2 T_{\mathbb{C}}) (1 + q^3 T_{\mathbb{C}})) \quad (q^3)
\]

\[
\equiv q^{-1} \left( \hat{A}(X) + \hat{A}(X, T_{\mathbb{C}}) q + \hat{A}(X, S^2 T_{\mathbb{C}} + T_{\mathbb{C}}) q^2
\right.
\]

\[
\left. + \hat{A}(X, S^3 T_{\mathbb{C}} + T_{\mathbb{C}} \otimes T_{\mathbb{C}} + T_{\mathbb{C}}) q^3 \right) \quad (q^3).
\]
We therefore would have:

\[
\hat{A}(X, S^2T_c + T_c) = \hat{A}(X, S^2T_c) + \hat{A}(X, T_c) = 196884,
\]

\[
\hat{A}(X, S^3T_c + T_c \otimes T_c + T_c) = \hat{A}(X, S^3T_c) + \hat{A}(X, T_c \otimes T_c) + \hat{A}(X, T_c) = 21493760.
\]

Now for each Riemannian metric on $X$ there is a canonical nowhere vanishing section of $S^2T_c$. For a Riemannian metric on $X$ yields a positive definite, symmetric bilinear form on each fibre of the tangent bundle of $X$, therefore a section of $S^2T^*$. But $T^*$ is isomorphic to $T$ by means of this metric, and we obtain a section of $S^2T$ and so also of $S^2T_c$. This section therefore defines a trivial line bundle $E$ lying in $S^2T_c$, hence we can split $S^2T_c$ with respect to the metric:

\[
S^2T_c = \tilde{S}^2T_c \oplus E
\]

\[
\Rightarrow \quad \hat{A}(X, S^2T_c) = \hat{A}(X, \tilde{S}^2T_c) + \hat{A}(X, E)
\]

\[
= \hat{A}(X, \tilde{S}^2T_c) + \hat{A}(X)
\]

\[
\Rightarrow \quad \hat{A}(X, \tilde{S}^2T_c) = 196883.
\]

This number 196883 is the dimension of the smallest (non-trivial) representation of the Monster.

For the next coefficient 21493760 we have

\[
T_c \otimes T_c = \Lambda^2T_c + S^2T_c,
\]

and so

\[
\hat{A}(X, S^3T_c) + \hat{A}(X, \Lambda^2T_c) = 21296876.
\]

This is the dimension of the next largest irreducible representation of the Monster.

It would be marvelous to find a 24-dimensional manifold as in the prize question, on which in addition the Monster acts by diffeomorphisms. Such an action would lift to an action on the tangent bundle and its symmetric and exterior powers. In addition, the Monster would then also act on the cohomology of the twisted Dirac operators, whose indices are given by the twisted $\hat{A}$-genera. Hence one would have a relation between the Monster (more precisely, its irreducible representations), certain bundles on $X$ and the coefficients of $j - 744$. Above all, one would possess a key to construct a great many representations of the Monster.

**Example:** Following Landweber and Stong, we shall consider the Witten genus of complete intersections. Thus, let $V_1^{(d_1)}, \ldots, V_r^{(d_r)}$ be hypersurfaces of degree $d_i$ in
$P_{n+r}(C)$. Assume the $V^{(d_i)}_i$ are smooth and intersect transversely (then their intersection is also smooth). The complete intersection $V_n = V^{(d_1, \ldots, d_r)}_n$ then has complex dimension $n$. Denote by $\omega \in H^2(P_{n+r}(C); \mathbb{Z})$ the canonical generator, the Poincaré dual of $P_{n+r-1}(C) \subset P_{n+r}(C)$. Then the total Chern class of $V_n$ is (cf. section 3.1):

$$c(V_n) = (1 + x)^{n+r+1} \cdot (1 + d_1 x)^{-1} \cdots (1 + d_r x)^{-1}|_{V_n}.$$ 

For the Witten genus of $V_n$ we obtain the formula:

$$\varphi_W(V_n) = \frac{x^{n+r+1} \cdot \sigma(d_1 x) \cdots \sigma(d_r x)}{\sigma(x)^{n+r+1} \cdot d_1 x \cdots d_r x}[V_n]$$

$$= \text{coefficient of } x^{n+r} \text{ in } \frac{x^{n+r+1} \cdot \sigma(d_1 x) \cdots \sigma(d_n x)}{\sigma(x)^{n+r+1}}$$

$$= \text{res}_0 \left( \frac{\sigma(d_1 x) \cdots \sigma(d_n x)}{\sigma(x)^{n+r+1}} \right).$$

We shall now determine this residue when $p_1(V_n) = 0$. We have:

$$p_1(V_n) = (n + r + 1 - (d_1^2 + \cdots + d_r^2)) \cdot x^2|_{V_n},$$

as one easily concludes from the formula for the total Chern class. Hence we obtain:

$$p_1(V_n) = 0 \text{ is equivalent to } n + r + 1 = d_1^2 + \cdots + d_r^2.$$ 

Now $\sigma(d_1 x) \cdots \sigma(d_r x)/\sigma(x)^{n+r+1}$ is an elliptic function if the number of zeroes and poles of the numerator is equal to that of the denominator, and the sum of the zeroes is equal to the sum of the poles (modulo the lattice). Now the $\sigma$-function has only simple zeroes at the lattice points, hence the factors of the numerator have zeroes at all $d_i$-division points, giving a total of $d_1^2 + \cdots + d_r^2$ simple zeroes. The denominator has an $(n + r + 1)$-fold zero at all lattice points. In case $p_1(V_n) = 0$, we have $n + r + 1 = d_1^2 + \cdots + d_r^2$: in addition, the sum of the zeroes is zero for each factor. Therefore the above quotient is an elliptic function, having a pole only at the origin (modulo the lattice). Hence its residue at the origin is equal to zero, since for elliptic functions the sum of the residues is always zero. Therefore:

$$p_1(V_n) = 0 \text{ implies } \varphi_W(V_n) = 0.$$ 

In particular, the prize question cannot be answered with complete intersections, since for $p_1(V_n) = 0$ the twisted $A$-genera above vanish.
6.4 The Witten genus and the Lie group $E_8$

We shall assume that $M$ is a $4k$-dimensional compact, orientable, differentiable manifold for which all composite Pontrjagin numbers vanish, i.e. with $p = 1 + p_1 + \cdots + p_k$ we have:

$$(p_{i_1} \cdots p_{i_r})[M] = 0 \quad \text{for all } i_1 + \cdots + i_r = k \text{ with } r > 1.$$  

The only remaining Pontrjagin number is $p_k[M]$. In addition, as earlier we shall require that $p_1 = 0$. In this situation, as expected, we obtain a much simplified formula for the Witten genus, since we can calculate modulo the Pontrjagin classes $p_1, \ldots, p_{k-1}$ and so can simply apply the Cauchy lemma of section 1.8 for the calculation of the genus. We recall that the characteristic power series has a representation as

$$\frac{x}{\sigma_L(x)} = \exp\left(\sum_{r=2}^{\infty} \frac{-B_{2r}}{2r \cdot (2r)!} E_{2r}(\tau) \cdot x^{2r}\right);$$

hence $\varphi_w(M)$ is a constant multiple of $E_{2k}$. The constant term of $E_{2k}$ is 1, while for $\varphi_w(M)$ it is $\hat{A}(M)$; therefore

$$\varphi_w(M) = \hat{A}(M) \cdot E_{2k}.$$  

This is not very surprising, since under our assumptions on the Pontrjagin numbers every genus is a multiple of $\hat{A}$.

**Example:** For $k = 2$, so that $M$ is an 8-dimensional manifold, we have:

$$\varphi_w(M) = \hat{A}(M) \cdot E_4$$  

$$\Rightarrow \frac{\varphi_w(M)}{\Delta^{1/3}} = \hat{A}(M) \cdot \frac{E_4}{\Delta^{1/3}} = \hat{A}(M) \cdot \hat{A}(M) \cdot q^{1/3} (1 + 248 \cdot q + 4124 \cdot q^2 + \cdots).$$

The power series for the cube root of $j$ (normalized as here) could have rational coefficients, having a three in the denominator, but the cube root of $j$ is in fact an integral power series.

Suppose that we had an 8-dimensional manifold $M$ with $p_1(M) = 0$ and $\hat{A}(M) = 1$. Then the above conditions are fulfilled, since the only Pontrjagin numbers in dimension 8 are $p_2^2$ and $p_2$. For such a manifold we have

$$\frac{\varphi_w(M)}{\Delta^{1/3}} = q^{-1/3} (1 + 248 \cdot q + 4124 \cdot q^2 + \cdots),$$

so by the previous formula (for $p_1 = 0$):

$$\frac{\varphi_w(M)}{\Delta^{1/3}} = q^{-1/3} \cdot \hat{A}(M, \bigotimes_{n=1}^{\infty} S^2 T_c)$$

$$\Rightarrow \hat{A}(M, T_c) = 248, \quad \hat{A}(M, T_c) + \hat{A}(M, S^2 T_c) = 4124,$$

$$\Rightarrow \hat{A}(M, S^2 T_c) = 3876 \quad \text{and} \quad \hat{A}(M, \overline{S^2 T_c}) = 3875.$$
Here one could again conjecture a relation to the irreducible representations of a group. For this we shall consider the exceptional Lie group $E_8$ (despite a close connection, the identical notation with the Eisenstein series $E_8$ is accidental). It has dimension 248 and therefore possesses a representation in this dimension, namely the adjoint representation on its Lie algebra. At the same time, this is the smallest irreducible representation of $E_8$. The next dimension in which an irreducible representation exists is precisely 3875. However, one cannot hope that $E_8$ acts non-trivially on our manifold, since then an $S^1 \subset E_8$ would also act non-trivially (each element lies in a maximal torus, hence also in an $S^1$). But this contradicts $\hat{A}(M) = 1$, since we have (cf. [AtHi70]) the

**Theorem** (Atiyah-Hirzebruch): *If the circle $S^1$ acts non-trivially on a connected spin manifold, then $\hat{A}(M) = 0$.*

But one could still hope that perhaps a large discrete subgroup of $E_8$ acts on a manifold of the type assumed to exist in this example. As already noted above, under our assumptions on the Pontrjagin numbers of the manifold, each genus is a multiple of the $\hat{A}$-genus; in particular, we have (by the Cauchy lemma):

$$\text{sign}(M) = -2^{2k+1}(2^{2k-1} - 1) \cdot \hat{A}(M).$$

Since the $\hat{A}$-genus is always integral up to a power of two in the denominator, $2^{2k-1} - 1$ must divide the signature of $M$. If in addition $M$ is a spin manifold, so that the second Stiefel-Whitney class $w_2(M)$ is equal to zero, then the twisted $\hat{A}$-genera are integral; since this is likewise true of $\Delta^{k/6}$, also

$$q^{-k/6} \cdot \hat{A}(M, \bigotimes_{n=1}^{\infty} S_q T_{\mathbb{C}}) \cdot \Delta^{k/6} = \varphi_W(M) = \hat{A}(M) \cdot E_{2k}$$

is integral. We therefore obtain from

$$E_{2k}(\tau) = 1 + \frac{4k}{-B_{2k}} \cdot \sum_{n=1}^{\infty} \sigma_{2k-1}(n) \cdot q^n$$

for $n = 1$ the divisibility condition:

$$\hat{A}(M) \equiv 0 \pmod{\text{numerator of the reduced representation of } B_{2k}/4k}.$$ 

For $k = 2, 3$ this numerator is equal to one ($E_4$ and $E_6$ are integral modular forms), but for larger $k$ this represents a proper divisibility. If we combine this with the above condition on the signature, then we have:

$$\text{sign}(M) \equiv 0 \pmod{2^{2k+1}(2^{2k-1} - 1) \cdot \text{numerator}(\frac{B_{2k}}{4k})}.$$ 

In the derivation of this result we have proceeded very crudely. More precisely, we have only used the integrality of the coefficient of $q$ in $\varphi_W(M)$; hence it suffices to require $\hat{A}(M, T_{\mathbb{C}}) \in \mathbb{Z}$ instead of $w_2 = 0$ to deduce the divisibility statement.
6.4 The Witten genus and the Lie group \( E_8 \)

We can obtain a small improvement of this result: For a spin manifold \( M \), the \( \hat{A} \)-genus \( \hat{A}(M) \) is always even if the dimension of \( M \) is divisible by 4 but not by 8 (cf. section 8.1). Putting \( a_k = 1 \) if \( k \) is even and \( a_k = 2 \) if \( k \) is odd, we therefore have:

\[
\text{sign}(M) \equiv 0 \quad (a_k 2^{2k+1}(2^{2k-1} - 1) \cdot \text{numerator}(\frac{E_{2k}}{\Delta_{k/6}})).
\]

**Example:** For \( k = 1 \) this means that \( \text{sign}(M) \equiv 0 \) (16). This result is sharp, since e.g. a \( K3 \)-surface has signature 16.

Now that we have derived a lovely result under strong assumptions on the Pontrjagin numbers of the manifold, obviously the question remains whether such manifolds exist. Milnor and Kervaire have reported on this problem at the 1958 International Congress of Mathematicians (cf. [MiKe58]). They investigated a particular kind of manifold:

**Definition:** A manifold is called parallelizable if its tangent bundle is trivial; it is called almost-parallelizable if its tangent bundle is trivial on the complement of a point.

For an almost-parallelizable manifold \( M^{4k} \) we obviously have \( w_2 = 0 \), since \( w_2 \) can be defined via obstruction theory on the 3-skeleton of a triangulation of the manifold, and this triangulation can be chosen so that the tangent bundle of \( M \) is trivial on the \((4k - 1)\)-skeleton, hence there is no obstruction to a section over this skeleton. The same argument also yields \( p_i = 0 \) for \( i < k \). Moreover, such a manifold is automatically orientable, since also the obstruction \( w_1 \) to orientability is zero.

Since all our conditions on characteristic classes are fulfilled by almost-parallelizable manifolds, our divisibility theorem holds for such manifolds. The condition of being almost-parallelizable is in fact stronger than we require, but Milnor and Kervaire have constructed almost-parallelizable manifolds whose signature not only satisfy the above divisibility relation, but in fact yield an equality:

**Theorem:** There are almost-parallelizable manifolds \( M_0^{4k} \) with

\[
\text{sign}(M_0^{4k}) = a_k 2^{2k+1}(2^{2k-1} - 1) \cdot \text{numerator}(\frac{E_{2k}}{\Delta_{k/6}}).
\]

The divisibility statement is therefore sharp. For the Witten genus of \( M_0^{4k} \) this means that:

\[
q^{-\frac{1}{8}} \cdot \hat{A}(M_0^{4k}, \bigotimes_{n=1}^{\infty} S_{4^n} T) = \frac{\hat{A}(M_0^{4k}) \cdot E_{2k}}{\Delta_{k/6}}
\]

\[
= -a_k \cdot \text{numerator}(\frac{E_{2k}}{\Delta_{k/6}}) \cdot E_{2k} \Delta_{k/6}.
\]

For \( M_0^8 \) we get \( j^{1/3} \), hence for \( M_0^8 \times M_0^8 \times M_0^8 \) we obtain the modular function \( j \); but this does not answer our prize question, since we want to attain instead \( j - 744 \).

Now to the construction of \( M_0^{4k} \), by means of plumbing!
6.5 Plumbing of manifolds

The manifold $M_0^{4k}$ of the last section will be constructed by judiciously gluing together several copies of the disk bundle associated to the tangent bundle of $S^m$. The gluing instructions are given by a suitable graph. This method of construction is called plumbing (cf. [MiKe58], [KeMi63], [Br72]).

We therefore consider $D(S^m) = \{x \in TS^m \mid |x| \leq 1\}$. One is given a graph as plan for the construction, such as the diagram for $E_8$:

![Diagram for $E_8$]

For each node (or vertex) one takes a copy of $D(S^m)$, and joins together two of these copies if there is an edge in the graph between the corresponding nodes. The manner in which the copies of $D(S^m)$ are joined is shown here in the case $m = 1$:

![Plumbing of disk bundles]

The boundary of the new manifold in this example is obviously an $S^1$, and the manifold is orientable. In the general case plumbing also yields an orientable manifold $X^{2m}$ with boundary. One can now easily determine the signature of this manifold. We recall that the signature of a 4k-dimensional, oriented manifold $X$ with boundary is defined as the signature of the quadratic form belonging to the intersection form on $H^{2k}(X, \partial X; \mathbb{Z}) \cong H_{2k}(X; \mathbb{Z})$, i.e.

$$a \in H^{2k}(X, \partial X; \mathbb{Z}) \mapsto (a \cdot a)[X, \partial X].$$
In $D(S^m)$ a canonical basis for the middle homology is given by the zero-section of the tangent bundle:

![Zero-section of the disc bundle $D(S^1)$](image)

Let $X_{E_8}^m$ be the resulting manifold in the construction using $E_8$. The cycles $s_1, \ldots, s_8$ intersect one another exactly as indicated in the $E_8$-diagram ($i \neq j$):

$$s_is_j = \begin{cases} 
0, & \text{if no edge joins vertices } i \text{ and } j, \\
\pm 1, & \text{otherwise.}
\end{cases}$$

The signs can be determined by the choice of an orientation of the $s_i$. The resulting matrix is symmetric for even $m$, anti-symmetric for odd $m$. We now consider the self-intersection numbers. For the $S^1$ the zero-section can be deformed so that it is nowhere zero, hence we obtain self-intersection number zero. This is not the case for $S^2$, since the deformation of the zero-section is given by a vector field on $S^2$, which is well-known to always have two zeroes (the Euler number) when counted correctly. We therefore have self-intersection number 2 here. In general, the Euler number of a sphere $S^m$ is equal to 2 for even $m$ and to 0 for odd $m$, hence:

$$s_is_i = \begin{cases} 
2, & \text{if } m \text{ is even,} \\
0, & \text{otherwise.}
\end{cases}$$

For the diagram $E_8$ we obtain the following matrix when $m = 2k$:

$$\begin{pmatrix}
2 & 1 \\
1 & 2 & 1 \\
1 & 2 & 1 \\
1 & 2 & 1 & 1 \\
1 & 2 & 1 \\
1 & 2 \\
1 & 2 \\
1 & 2
\end{pmatrix}$$

It follows that the intersection form is positive definite with determinant 1.
In our example with $S^1$ we obtain a 2-dimensional manifold $X^2_{E_8}$ whose first (i.e. middle) homology is generated by eight cycles, i.e. $b_1 = 8$. If we collapse the boundary, an $S^1$, to a point, a Riemann surface of genus four (Euler number $-6$) results. In other words: $X^2_{E_8}$ is a Riemann surface of genus four with a hole.

In the general case, the boundary $V^{2m-1}$ of $X^{2m}$ is a homology sphere if the determinant of the intersection form of $X$ is equal to $\pm 1$. For $m > 2$ the boundary is also simply connected, hence for $m \neq 2$ is even a homotopy sphere (all homotopy groups of $V^{2m-1}$ are the same as for the sphere $S^{2m-1}$). Now in 1960 Stephen Smale proved the following theorem (cf. [Sm60]):

**Theorem (Smale):** Each homotopy sphere $V^k$ with $k > 4$ is homeomorphic to the sphere $S^k$.

For us this means that the boundary $V^{2m-1}$ for $m \neq 2$ is therefore homeomorphic to the sphere $S^{2m-1}$. Now the disk bundle $D(S^m)$ is a parallelizable manifold: If $\pi : D(S^m) \rightarrow S^m$ is the projection we have $T(D(S^m)) = \pi^*(T(S^m) \oplus T(S^m))$ and $T(S^m) \oplus T(S^m)$ is a stably-trivial bundle over $S^m$ with rank $2m$, so it is trivial. Hence the manifold $X_{E_8}^{2m}$ obtained from $D(S^m)$ by plumbing is again parallelizable.

We have thereby found an example of a so-called exotic sphere, i.e. $V^{2m-1}$ is homeomorphic, but not diffeomorphic to $S^{2m-1}$! For if $V^{2m-1}$ were diffeomorphic to $S^{2m-1}$, then

$$X_{E_8}^{2m} \cup_{S^{2m-1}} D^{2m}$$

would be a $2m$-dimensional manifold which is parallelizable in the complement of a point, hence almost-parallelizable. However the signature does not change when one attaches a disk, and so for $m = 2k$ it remains equal to 8. From our earlier considerations on the divisibility properties of the signature of almost-parallelizable manifolds we obtain the result:

$$a_k 2^{2k+1} (2^{2k-1}) \cdot \text{numerator} \left( \frac{E_k}{4k} \right) \text{ divides } 8.$$

But for $k = 2$ the left side is $8 \cdot 28$. Contradiction!

The Milnor spheres $V^{2k-1}$ are therefore not diffeomorphic to $S^{4k-1}$, and

$$X_{E_8}^{2m} \cup_{S^{3m-1}} D^{2m}$$

only has a differentiable structure on the complement of a point. We now denote by $bP_{4k}$ the set of diffeomorphism classes of oriented spheres $\Sigma^{4k-1}$ which bound compact parallelizable manifolds (respecting orientations). This is a group with the connected sum as group operation. One forms the connected sum of two manifolds by joining the two manifolds with a handle. For $k \geq 2$ this group is generated by the $V^{4k-1}$. The order of the group is precisely

$$n_k = \frac{1}{8} \left( a_k 2^{2k+1} (2^{2k-1} - 1) \cdot \text{numerator} \left( \frac{E_k}{4k} \right) \right),$$
hence the boundary connected sum of $n_k$ copies of the manifold $X_{E_k}$ has the standard sphere as boundary, to which one can glue a disk smoothly. Since the signature of two manifolds adds under the formation of their connected sum, the resulting manifold is therefore the desired manifold $M_0^{4k}$. 
7  Riemann-Roch and elliptic genera in the complex case

7.1 Elliptic genera of level $N$

Let $\tau \in \mathfrak{h}$ and $L = 2\pi i (\mathbb{Z}\tau + \mathbb{Z})$ be a lattice. We seek a function $h(x)$ on $\mathbb{C}$, which is elliptic with respect to $L$ and on $\mathbb{C}/L$ has a zero of order $N$ at the origin and a pole of the same order at a point $P$. In order that such a function exist it is necessary that $N \cdot 0 - N \cdot P = 0$ ($L$), hence the point $P$ must be a non-zero $N$-division point of $\mathbb{C}/L$. These $N$-division points are precisely the points $P$ of the form:

$$P = 2\pi i \frac{k\tau + l}{N} \neq 0$$

for $k, l \in \mathbb{Z}$.

If we normalize the function $h$ by $h(x) = x^N + \cdots$, then it is uniquely determined for a fixed $N$-division point $P$ (cf. Appendix I, §6). Under these assumptions, we can extract a unique $N$-th root $f$ with the normalization

$$f(x) = \sqrt[\sqrt{N}]{h(x)} = x + \cdots$$

This is elliptic with respect to a sublattice $\tilde{L}$ of index $N$ in $L$. For fixed $k, l$ the power series

$$Q(x) = \frac{x}{f(x)} = 1 + b_1 x + b_2 x^2 + \cdots$$

is therefore uniquely specified. The coefficients $b_r$ depend on $\tau$; they are modular forms of weight $r$ for a certain modular group (cf. Appendix I, §6). This is not the full modular group $SL_2(\mathbb{Z})$, since the chosen $N$-division point $P$ must transform correctly. For $k = 0$ and $(l, N) = 1$ ($P$ a primitive $N$-division point) one obtains as modular group for the $b_r$ the group

$$\Gamma_1(N) = \{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in SL_2(\mathbb{Z}) \mid \begin{pmatrix} a & b \\ c & d \end{pmatrix} \equiv \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} (N) \}.$$  

We now consider the genus defined by this power series $Q$. Thus let $X$ be a complex manifold of dimension $d$, with total Chern class given by:

$$c(X) = 1 + c_1(X) + \cdots + c_d(X) = (1 + x_1) \cdots (1 + x_d), \quad c_i \in H^{2i}(X; \mathbb{Z}).$$

The genus $\varphi_{N,p}$ corresponding to $Q$ is then

$$\varphi_{N,p}(X) = \left( \prod_{i=1}^{d} \frac{x_i}{f(x_i)} \right) [X].$$
This is an expression in the coefficients of $Q(x)$ of weight $d$, hence a modular form of weight $d$, on $\Gamma_1(N)$ if $k = 0$, i.e. if $P = 2\pi il/N$ with $0 < l < N$. In fact, if $(l, N) = n \neq 1$ then we obtain the larger modular group $\Gamma_1(N/n) \supset \Gamma_1(N)$. For $k \neq 0$ different modular groups arise.

This genus is called an elliptic genus of level $N$. For $N = 2$ this is our original elliptic genus; the generalization to arbitrary $N$ was already proposed by Witten.

In the case $N = 2$ one has the involution $x \mapsto -x$ on $\mathbb{C}/L$. This leaves the origin and $P$ fixed and so also $h$, since we have normalized $h$ to begin with $x^2$. Hence $h$ is even, as well as also $Q(x) = x/\sqrt{h(x)}$. For the calculation of the corresponding genus one therefore needs only the elementary symmetric functions in the squares of the $x_i$, hence the Pontrjagin classes. Therefore one can also define the elliptic genus of level two for differentiable manifolds. For $k = 0$ one obtains in this case modular forms on $\Gamma_1(2) = \Gamma_0(2)$.

### 7.2 The values at the cusps

For the elliptic genera of level two the values at the cusps of $\Gamma_0(2)$ are the well-known signature ($L$-genus) and $\hat{A}$-genus. We are therefore also interested in the values at the cusps of $\Gamma_1(N)$ for the elliptic genera of level $N$. One obtains these values by introducing the local uniformizer $q = e^{2\pi i \tau}$ for the cusp $\infty$, for example, and considering the Fourier expansion $a_0 + a_1 q + \cdots$ of the modular form at $\infty$. The value at $\infty$ is then $a_0$. For modular forms of odd weight this is only well-defined up to sign (cf. Appendix I, §1). For the values at the other cusps, one transforms them to $\infty$ and then proceeds analogously. We shall now investigate these values.

Thus let $X$ be a compact, complex manifold of complex dimension $d$. Then the Hodge numbers $h^{p,q}$ are defined (cf. section 5.4), and as previously considered the $p$-th holomorphic Euler number is defined as:

$$\chi^p := \sum_{q=0}^{d} (-1)^q \cdot h^{p,q}.$$  

$\chi^0$ is just the arithmetic genus, and we have $\chi^p = (-1)^d \chi^{d-p}$. We have already shown that $\chi^p$ is the index of a suitable elliptic complex (the Dolbeault complex). We further defined

$$\chi_y(X) = \sum_{p=0}^{d} \chi^p(X) \cdot y^p;$$

the Atiyah-Singer index theorem yields

$$\chi_y(X) = \prod_{i=1}^{d} \left( x_i \frac{1 + y \cdot e^{-x_i}}{1 - e^{-x_i}} \right)[X].$$
Since the power series on the right side does not begin with 1, we must normalize it in order to obtain a genus:

\[
\frac{\chi_2(X)}{(1 + y)^d} = \prod_{i=1}^{d} \left( x_i \frac{1 + y \cdot e^{-x_i}}{1 - e^{-x_i}} \cdot \frac{1}{1 + y} \right) [X].
\]

Unfortunately we no longer obtain \( \chi_{-1}(X) \), the Euler number \( e(X) \) of \( X \). For \( y = 1 \) we have \( \chi_1(X) = \text{sign}(X) \) which is already defined for differentiable manifolds.

We now consider a different genus. Let \( K = \Lambda^d T^* \) be the canonical line bundle of \( X \), and \( D \) an arbitrary divisor on \( X \). We define

\[
\chi(X, D) = \sum_{i=0}^{d} (-1)^i \dim H^i(X; \Omega^0(D)),
\]

where \( \Omega^0(D) \) is the sheaf of meromorphic functions \( f \) with \( (f) + D \geq 0 \) (resp. germs of holomorphic sections of the line bundle associated to \( D \)). The Riemann-Roch theorem yields:

\[
\chi(X, D) = (\text{ch}(D) \cdot \text{td}(T X))[X]
= (e^{c_1(D)} \cdot \prod_{i=1}^{d} \frac{x_i}{1 - e^{-x_i}})[X].
\]

Since \( c_1(K) = -(x_1 + \cdots + x_d) \), we have:

\[
\chi(X, K^\tau) = \left( \prod_{i=1}^{d} e^{-\tau x_i} \frac{x_i}{1 - e^{-x_i}} \right)[X].
\]

Hence \( \chi(X, K^\tau) \) is the genus associated to the power series

\[
Q(x) = e^{-\tau x} \cdot \frac{x}{1 - e^{-x}}.
\]

One can also consider \( r \in \mathbb{Q} \) formally and so obtains a genus from the same formula, which is in general no longer integral. Sometimes \( K \) is the \( N \)-th power of a line bundle (which holds precisely when \( c_1(X) \equiv 0 \ (N) \)). In this case, the genus \( \chi(X, K^r) \) corresponding to \( r = k/N \) is obviously integral. For \( N = 2 \) this means the purely topological condition \( w_2(X) = 0 \), but for \( N > 2 \) we need the complex structure.

We now turn to the values at the cusps. Let \( P \neq 0 \) be a fixed \( N \)-division point in \( \mathbb{C}/L, \ L = 2\pi i(2\pi \tau + Z) \). Without restriction we may assume that \( P = 2\pi i/N \). For a different \( N \)-division point we obtain a different modular group. Just as is the case for level two, the choice of a different point \( P \) corresponds to the expansion at a different cusp (cf. Appendix I, §6). Given \( L \) and \( P \), we have defined a power series \( f(x) = \sqrt[2]{h(x)} \) in the above discussion. The elliptic genus of level \( N \) corresponding
to \(Q(x) = x/f(x)\) yields modular forms on \(\Gamma_1(N)\) of weight \(d\). For the values at the cusps, we can formulate the following assertion:

**Theorem:** The values of the elliptic genus of level \(N\) at the cusps of \(\Gamma_1(N)\) are:

1. \(\chi_y(X)/(1+y)^d\), where \(-y = e^{2\pi i l/N} \neq 1\) is an \(N\)-th root of unity with \(0 < l < N\).
2. \(\chi(X, K^{k/N})\) with \(0 < k < N\).

**Proof:** The expansion at some cusp of the elliptic genus for a fixed \(N\)-division point \(P\) corresponds to the expansion at the cusp \(\infty\) for some other choice of \(N\)-division point. Therefore the set of values at the cusps for a fixed \(N\)-division point is the same as the set of values at the cusp \(\infty\) for all \(N\)-division points \(P = 2\pi i(k\tau + l)/N\).

These can be easily obtained from Appendix I, Theorem 6.4 (i). For \(k = 0\) i.e. \(P = 2\pi i l/N\) we get the value \(\chi_y(X)/(1+y)^d\), where \(-y = e^{2\pi i l/N}\), for \(0 < k < N\) and \(l\) arbitrary we get \(\chi(X, K^{k/N})\).

**Remark:** The values at the cusps are in general not all distinct, since the number \(\text{cu}(N)\) of cusps of \(\Gamma_1(N)\) is given, for \(N = 3\) or \(N > 4\), by (cf. Appendix I, Corollary 7.11)

\[
\text{cu}(N) = \frac{1}{2} \sum_{m \mid N} \varphi(m) \varphi(N/m),
\]

where \(\varphi\) denotes the Euler \(\varphi\)-function. Hence for a prime \(N = p \neq 2\) there are \(p - 1\) cusps, but we have listed \(2(p - 1)\) values. This comes about since these values are only well-defined up to sign. For \(N = 2\), in case 1) only \(y = 1\) occurs, i.e. the signature; in case 2) only \(k = 1\), the \(\hat{A}\)-genus, is possible. These are the genera which we have already obtained at the two cusps of \(\Gamma_1(2) = \Gamma_0(2)\).

### 7.3 The equivariant case and multiplicativity

There are several classical results about these values at the cusps. Assume that the circle \(S^1\) acts non-trivially by holomorphic automorphisms on our complex manifold \(X\). Then \(S^1\) acts on the finite dimensional vector spaces \(H^{p,q}(X)\). We thereby obtain a representation of \(S^1\). The corresponding character is a finite Laurent series in \(q = e^{2\pi i \tau} \in S^1, \tau \in \mathbb{R}\). Taken together, these representations yield as character a finite Laurent series \(\chi_y(q, X)\) in \(q\) with \(\chi_y(id, X) = \chi_y(X)\). As we have seen in section 5.4, \(\chi_y(q, X) \equiv \chi_y(X)\) is constant.

If \(\alpha_1(X) \equiv 0 (N)\), i.e. \(K = L^N\) for a line bundle, then \(\chi(X, K^{k/N}) = \chi(X, L^k)\) is integral. If \(S^1\) acts non-trivially on \(X\), then the character satisfies \(\chi(q, X, L^k) \equiv 0\) (cf. [Ha78] and Appendix III).
Example: For $N = 2$, $c_1(X) \equiv 0 (2)$ is precisely the condition $w_2(X) = 0$, which means $X$ has a spin structure. Then $\hat{A}(X) = \chi(X, L)$ where $K = L^2$, so $L$ is a root of the canonical bundle of $X$. Now the theorem of Atiyah-Hirzebruch (cf. [AtHi70]) states that the character associated to $\hat{A}(X)$ is zero if $S^1$ acts non-trivially on $X$.

Now we shall observe that the values at the cusps vanish on the projective spaces of dimension $rN - 1$, $r > 0$:

If $X = P_d(C)$ is a complex projective space and $E$ is the line bundle determined by the divisor $P_{d-1}(C) \subset P_d(C)$ (so that $E = H^*$), then the canonical bundle is $K = E^{-(d+1)}$. As a special case of a simple residue calculation we obtain (cf. [Hi54]):

$$\chi(P_d(C), E^i) = \left(\begin{array}{c} i+d \\ d! \end{array}\right) = \frac{(i+1)\cdots(i+d)}{d!}.$$

This is a polynomial of degree $d$ in $i$ with the zeroes $-1, \ldots, -d$. For $d = rN - 1$, so that $N = (d+1)/r$, we then have

$$\chi(P_d(C), K^{k/N}) = \chi(P_d(C), E^{-kr}) = 0 \text{ for all } 0 < k < N.$$

In addition, we have (cf. section 5.4):

$$\chi_y(P_{rN-1}(C)) = 1 - y \pm \cdots + (-y)^rN-1 = \frac{1 - (-y)^rN}{1 - (-y)},$$

since the $h^{p,q}$ are all zero for $p \neq q$, i.e. $h^{p,p}$ is the $2p$-th Betti number, so is one. From this it follows that

$$\chi_y(P_{rN-1}(C)) = 0 \text{ for } -y = e^{2\pi i/l}/N, 0 < l < N.$$

**Theorem:** The elliptic genus vanishes (identically as a modular form) for complex projective spaces of dimension $rN - 1$; indeed it vanishes for all manifolds which are total space of a bundle with fibre $P_{rN-1}(C)$.

**Proof:** The correct proof follows the same lines as for the corresponding theorem about elliptic genera of level two in section 4.6 (use the fact that $f(x - x_1) \cdots f(x - x_{rN})$ is elliptic for $L = 2\pi i(Zr + Z)$).

The vanishing on $P_{rN-1}(C)$ was to be expected, since as we have seen all values at the cusps vanish for $P_{rN-1}(C)$. We therefore have a cusp form, but one does not come by cusp forms so cheaply.

For a result on multiplicativity in fibre bundles with fibre having first Chern class divisible by $N$ we refer to Appendix III.
7.4 The loop space and the expansion at a cusp

We shall now attempt to define the expression $\chi_y(q, L_X)$ for the loop space $L_X$. We shall proceed by analogy with the case of elliptic genera of level two. On the loop space $L_X$ there is a canonical $S^1$-action having as fixed point set $(L_X)^{S^1}$ precisely $X \subset L_X$, the space of constant loops. A tangent vector to a constant loop $p \in X$ is a loop in $T_p X$. This can be regarded as a periodic mapping of $\mathbb{R}$ into a finite dimensional complex vector space, and so has a Fourier expansion with coefficients in $T_p X$. We obtain the splitting

$$T_p L_X = \sum_{n=-\infty}^{\infty} q^n T_p X,$$

where $q \in S^1$ acts on the $n$-th summand as multiplication by $q^n$.

We now apply the equivariant Atiyah-Singer index theorem formally. The $\chi_y$-genus is the index of the Dolbeault complex, computed as the sum of local contributions which are determined by the normal bundle to the fixed components. Hence we should have the formula:

$$\chi_y(q, L_X) = \left( \prod_{i=1}^{d} x_i \left( \prod_{n=-\infty}^{\infty} \frac{1 + yq^n e^{-x_i}}{1 - q^n e^{-x_i}} \right) \right) [X].$$

For $q = 0$ this expression certainly yields $\chi_y(X)$, but since $\sum_{n=-\infty}^{\infty} q^n$ does not converge there is evidently a serious problem with convergence. The product cannot even be multiplied out into a formal power series. We therefore separate the factors for positive and negative $n$, multiplying the latter by $q^n e^{x_i}$ to obtain:

$$\chi_y(q, L_X) = \left( \prod_{i=1}^{d} x_i \cdot \frac{1 + ye^{-x_i}}{1 - e^{-x_i}} \left( \prod_{n=1}^{\infty} \frac{1 + yq^n e^{-x_i}}{1 - q^n e^{-x_i}} \right) \right) [X].$$

For $q \in S^1$ this expression still fails to converge; instead we shall consider $q = e^{2\pi i \tau}, \tau \in \mathbb{H}$. Then $\text{Im}(\tau) > 0$, hence $|q| < 1$, and the product does indeed converge. Since for the values at the cusps $-y$ is always an $N$-th root of unity, we shall also consider $-y = \eta$ with $\eta^{N} = 1$:

$$\chi_{-\eta}(q, L_X) = \left( \prod_{i=1}^{d} x_i \cdot \frac{1 - \eta e^{-x_i}}{1 - e^{-x_i}} \left( \prod_{n=1}^{\infty} \frac{1 - \eta q^n e^{-x_i}}{1 - q^n e^{-x_i}} \left( \frac{(1 - q^n e^{-x_i})}{(1 - q^n e^{-x_i})} \right) \right) \right) [X].$$

To cancel the $\eta$-factor we multiply formally by $\eta^{-d} \sum_{n \geq 1} = \eta^{d/2}$ ($\zeta(0) = -1/2$). If in addition $d \equiv 0 \pmod{(2N)}$ so that $\eta^{d/2} = 1$, with $\eta = e^{a}$ we obtain:

$$\chi_{-\eta}(q, L_X) = \left( \prod_{i=1}^{d} x_i e^{a/2} \frac{\sinh((x_i - \alpha)/2)}{\sinh(x_i/2)} \right) \left( \prod_{n=1}^{\infty} \frac{1 - q^n e^{-(x_i - \alpha)}}{1 - q^n e^{-x_i}} \left( \frac{(1 - q^n e^{-(x_i - \alpha)})}{(1 - q^n e^{-(x_i - \alpha)})} \right) \right) [X].$$
7.5 The differential equation

We can write this more simply in terms of the \( \Phi \)-function. The \( \Phi \)-function is defined by

\[
\Phi(x) = 2 \cdot \sinh(x/2) \cdot \prod_{n=1}^{\infty} \frac{(1 - q^n e^x)(1 - q^n e^{-x})}{(1 - q^n)^2}.
\]

For \( |q| < 1 \), this product yields a holomorphic function in \( x \) with zeroes of order 1 at \( 2\pi i(\mathbb{Z} \tau + \mathbb{Z}) \). We have

\[
\chi_y(q, \mathcal{L}X) = \left( \prod_{i=1}^d x_i e^{\alpha/2} \frac{\Phi(x_i - \alpha)}{\Phi(x_i)} \right) [X]
\]

with \( -y = e^\alpha \), \( (-y)^N = 1 \).

For the elliptic genus of level \( N \) we have as Fourier expansion (see Appendix I, Theorem 6.4)

\[
f(x) = \frac{\Phi(x)\Phi(-\alpha)}{\Phi(x - \alpha)}.
\]

The normalization factor \( e^{d\alpha/2} \cdot \Phi(-\alpha)^d \) is a modular form of weight \( d \) on \( \Gamma_1(N) \) when \( d \equiv 0 \mod N \) (for \( N \) odd) resp. \( d \equiv 0 \mod 2N \) (for \( N \) even). Hence for \( (-y)^N = 1 \), \( \chi_y(q, \mathcal{L}X) \) is a modular function for \( \Gamma_1(N) \) under these assumptions.

7.5 The differential equation

The function \( h = f^N \) is elliptic with respect to a lattice \( L \). Hence also \( f'/f = \frac{h'')}{h} \) is elliptic with respect to \( L \). This function has precisely two poles, namely a pole of order one at the origin as well as at the chosen \( N \)-division point \( P \). Hence \( f'/f \) defines a double covering of \( \mathbb{C}/(\mathbb{C}+L) \) by \( \Gamma_1(C) \). On the curve \( \mathbb{C}/L \) there is the involution \( \tau : x \mapsto -x + P \). The function \( f(x)f(-x + P) \) is elliptic with respect to \( L \) (under translation by lattice vectors inverse factors from \( f(x) \) and \( f(-x + P) \) cancel) and has no poles or zeroes, hence it is constant:

\[
f(x)f(-x + P) = f(P/2)^2 = e^{-2} \neq 0.
\]

Here \( P/2 \) is any of the four points \( \tilde{P} \) in \( \mathbb{C}/L \) with \( 2\tilde{P} = P \). Logarithmic differentiation then yields:

\[
\frac{f'(x)}{f(x)} - \frac{f'(-x + P)}{f(-x + P)} = 0.
\]
Hence \( f'/f \) is invariant under the involution \( \tau \). We thereby obtain an isomorphism \( f'/f : (\mathbb{C}/L)/\tau \to P_3(\mathbb{C}) \), so that each function on \((\mathbb{C}/L)/\tau\) is a rational function of \( f'/f \). Now the function

\[
\frac{1}{f(x)^N} + \frac{1}{f(-x + P)^N} = \frac{1}{f(x)^N} + c^{2N} f(x)^N
\]

is certainly invariant under \( \tau \) and also is elliptic with respect to \( L \), since \( f^N \) is; hence it is a rational function of \( \xi = f'/f \). Furthermore it has only poles at the origin, and at the point \( P \), both of order \( N \). Since the pole at the origin has leading coefficient 1, while \( \xi \) has a simple pole with residue 1 there, we even have an equation of the form

\[
\frac{1}{f^N} + a_{2N} \cdot f^N = \xi^N + a_1 \cdot \xi^{N-1} + \cdots + a_{N-1} \cdot \xi + a_N,
\]

for we can choose the coefficients \( a_1, \ldots, a_N \) so that both sides have the same principal part at the origin. Since they are invariant under \( \tau \), they also have the same principal parts at \( P \); since they are both elliptic with respect to \( L \), they therefore coincide. Here we have put \( a_{2N} = c^{2N} \), so that \( a_{2N} \neq 0 \). The coefficients \( a_1, \ldots, a_N \) and \( a_{2N} \) can be determined directly from the coefficients of \( \xi \). Hence they are modular forms (on \( \Gamma_1(N) \) if \( P = 2\pi i/N \)) of weight equal to their index (cf. Appendix I, §7).

We shall denote the polynomial of degree \( N \) on the right side by \( P_N \). We claim that in this polynomial the coefficient \( a_{N-1} \) is equal to zero. Equivalently, we must show that the derivative of \( P_N \) has a zero at the origin. We differentiate the above differential equation and obtain

\[
P'_N(\xi) \cdot \xi' = \xi \cdot N \cdot \left( a_{2N} \cdot f^N - \frac{1}{f^N} \right).
\]

Since the function \( \xi \) is elliptic with respect to \( L \) but is non-constant, there is a point in \( \mathbb{C}/L \) at which it vanishes to an order \( e \). Since the factor in the parentheses on the right only has a pole where \( \xi = f'/f \) does not vanish, the order of the zero at this point for the right side of the equation is at least \( e \), since \( \xi' \) only vanishes to order \( e - 1 \), we conclude that \( P'_N(0) = 0 \).

**Example:** For \( N = 2 \) the differential equation has the following form:

\[
f^{-2} + a_4 \cdot f^2 = (f'/f)^2 + a_2
\]

\[
\Rightarrow f'^2 = 1 - a_2 \cdot f^2 + a_4 \cdot f^4.
\]

With \( a_2 = 2\delta \) and \( a_4 = \epsilon \) this is the well-known differential equation for elliptic genera of level two. For arbitrary \( \epsilon \) and \( \delta \) with \( \epsilon \neq 0 \) and \( \epsilon - \delta^2 \neq 0 \) this determines an elliptic function.

Each differential equation as above yields a unique (up to normalization) power series \( f(x) \). For arbitrary coefficients \( a_r \), \( f(x) \) will not be an elliptic function. Our \( a_r \).
were in fact modular forms of weight $r$, depending on a lattice with $N$-division point; evidently they must satisfy several relations, since there are not so many algebraically independent modular forms. What relations must the $a_r$ for an arbitrary $N$ satisfy, in order that one obtain an elliptic function?

The function $\eta = (\sigma \tau)^{-1} + \sigma \tau$ is not elliptic for $L$, but rather for a sub-lattice $\bar{L}$ of index $N$ in $L$. However the involution $\sigma \tau$ exists on $C/\bar{L}$ as well as on $C/L$, and $\eta$ is likewise invariant under $\sigma \tau$. If one divides both these curves by the involution, then both become rational curves, i.e. isomorphic to $P_1(C)$. The function

$$\eta : P_1(C) \cong (C/\bar{L})/\tau \to (C/L)/\tau \cong P_1(C)$$

is an $N$-fold covering. It defines the extension of degree $N$ of the function field on $(C/L)/\tau$ to the function field of $(C/\bar{L})/\tau$. In particular, as can also be established on elementary algebraic grounds, $(\sigma \tau)^{-N} + (\sigma \tau)^N$ is a polynomial of degree $N$ in $\eta = (\sigma \tau)^{-1} + \sigma \tau$; we denote this polynomial by $\bar{T}_N$.

**Example:** The first polynomials $\bar{T}_N$ are:

$$z^{-2} + z^2 = (z^{-1} + z)^2 - 2 \quad \Rightarrow \quad \bar{T}_2(z) = z^2 - 2,$$

$$z^{-3} + z^3 = (z^{-1} + z)^3 - 3(z^{-1} + z) \quad \Rightarrow \quad \bar{T}_3(z) = z^3 - 3z,$$

$$z^{-4} + z^4 = (z^{-1} + z)^4 - 4(z^{-1} + z)^2 + 2 \quad \Rightarrow \quad \bar{T}_4(z) = z^4 - 4z^2 + 2.$$

We therefore obtain, from the above differential equation, the equation

$$\bar{T}_N(\eta) = c^{-N} \cdot P_N(\xi).$$

The curve in the $(x,y)$-plane defined by the equation $\bar{T}_N(x) = c^{-N} \cdot P_N(y)$ is parametrized by $\xi$ and $\eta$, hence is isomorphic to $(C/\bar{L})/\tau$ and so is rational. Since it is given by an equation of degree $N$, it must have a large number of singularities. A point $(x,y)$ on this curve is singular if and only if $x$ and $y$ are critical points of $c^{-N}P_N$ resp. $\bar{T}_N$ and the critical values coincide.

The critical points and values of $\bar{T}_N$ are easily obtained using the so-called Chebyshev polynomials $T_N$. These are defined by the equation

$$\cos(N\theta) = T_N(\cos(\theta)).$$

Here is a list of the first few Chebyshev polynomials:

$$T_1(x) = x, \quad T_2(x) = 2x^2 - 1,$$

$$T_3(x) = 4x^3 - 3x, \quad T_4(x) = 8x^4 - 8x^2 + 1.$$
we obtain the relation

\[ \tilde{T}_N(x) = 2 \cdot T_N(x/2). \]

From the defining equation of \( T_N \) we see, that the zeroes of \( T'_N \) are \( x_j = \cos(\pi j/N) \) with \( 0 < j < N \). At these \( N - 1 \) points, \( T_N \) has local maxima or minima, all with the values \( \pm 1 \); more precisely:

\[ \begin{align*}
N \text{ even} & \Rightarrow (N-2)/2 \text{ times value } 1, \ N/2 \text{ times value } -1, \\
N \text{ odd} & \Rightarrow (N-1)/2 \text{ times value } 1, (N-1)/2 \text{ times value } -1.
\end{align*} \]

For \( N = 8 \) we obtain the following figure:

For the polynomials \( \tilde{T}_N(x) = 2 \cdot T_N(x/2) \) the \( N - 1 \) critical points are \( \tilde{x}_j = 2 \cos(\pi j/N) \) with \( 0 < j < N \) and the critical values are \( \pm 2 \); the distribution of signs is the same as for the Chebyshev polynomials.

So we expect that most of the critical values of the polynomials \( P_N \) arising in our differential equation are equal to \( \pm 2e^N \). The following discussion will give a more precise result.

The function \( \xi^2 \) is elliptic with respect to \( L \) and invariant under the involution \( \tau \). It has a pole of order four at the origin and at the point \( P \) and its Laurent series at the origin starts with \( \frac{1}{x^4} + \cdots \). Therefore there is as above a normalized polynomial \( Q(x) = x^4 + q_1 \cdot x^3 + q_2 \cdot x^2 + q_3 \cdot x + q_4 \) with

\[ Q(\xi) = \xi^2. \]
The curve given by the equation \( y^2 = Q(x) \) is therefore parametrized by \( \mathbb{C}/L \), by means of \( \xi \) and \( \xi' \). The function \( \xi \) assumes each value twice on \( \mathbb{C}/L \) (at points which are exchanged with one another by the involution \( \tau \)); its derivative \( \xi' \) has different signs at the corresponding points. Therefore this parametrization is an isomorphism apart from the poles of \( \xi \) (at 0 and \( P \)).

There is a close relation between the polynomials \( Q \) and \( P_N \):

\[
P_N(\xi) = f^{-N} + a_{2N} \cdot f^N
\]

\[
\Rightarrow \quad P'_N(\xi) \cdot \xi' = N \cdot \xi \cdot (-f^{-N} + a_{2N} \cdot f^N)
\]

\[
\Rightarrow \quad P'_N(\xi)^2 \cdot \xi'^2 = N^2 \cdot \xi^2 \cdot ((f^{-N} + a_{2N} \cdot f^N)^2 - 4a_{2N})
\]

As one easily sees from this equation, away from the origin \( P_N \) has only critical points of order precisely two with critical values \( \pm \sqrt{4a_{2N}} = \pm 2c^N \). So all the polynomials \( P_N \) occurring in the differential equation for \( f \) are so-called almost-Chebyshev polynomials.†

**Definition:** A polynomial \( P_N(x) = x^N + \cdots \) is called a *normalized almost-Chebyshev polynomial* if \( P'_N(x) = N \cdot x \cdot (x - \xi_1) \cdots (x - \xi_{N-2}) \) and the critical values \( P_N(\xi_1), \ldots, P_N(\xi_{N-2}) \) are equal up to sign.

### 7.6 The modular curve

The existence of the equation

\[
Q \cdot (P'_N/x)^2 = N^2 (P_N^2 - 4a_{2N})
\]

relating the polynomials \( P_N \) and \( Q \) gives us conditions for their coefficients. By differentiating it we obtain:

\[
Q' \cdot (P'_N/x)^2 + 2Q \cdot (P'_N/x) \cdot (P''_N \cdot x - P'_N)/x^2 - 2N^2 P_N P'_N = 0
\]

\[
\Rightarrow \quad Q' \cdot (P'_N/x) + 2Q \cdot (P''_N \cdot x - P'_N)/x^2 - 2N^2 P_N \cdot x = 0
\]

(here both \( P'_N/x \) and \( (P''_N \cdot x - P'_N)/x^2 \) are polynomials in \( x \)).

This yields \( N + 2 \) equations for the coefficients \( q_1, q_2, q_3, q_4 \) of \( Q \) and \( a_1, \ldots, a_N \) of \( P_N \). Since the polynomial \( Q \) is monic, the equation of highest degree is always satisfied. The next equations successively determine the \( a_r \) as homogeneous polynomials of weight

---

† F.H.: This terminology was used during my course. I did not know that these polynomials exist in the literature under the name Zolotarev polynomials. I wrote to Prof. Rivlin about the almost-Chebyshev polynomials and got from him the information on Zolotarev polynomials.
In the case of weights 1 to 4. Since for our construction of the elliptic genus $a_{N-1} = 0$, one obtains a homogeneous equation of weight $N - 1$ in $q_1, \ldots, q_4$. There still remains the equation for the constant term, which yields a second condition of weight $N + 1$ on $q_1$ to $q_4$. These two equations determine those polynomials $Q$ for which a polynomial $P_N$ with $Q \cdot (P'_N/x)^2 = N^2 \cdot (P^2_N - 4a_{2N})$ exists (with $a_{2N} = (a_N/2)^2 - q_4(a_{N-2}/N)^2$).

**Example:** For $N = 2$ we have

$$(4x^3 + 3q_1x^2 + 2q_2x + q_3) \cdot 2 + 2Q \cdot 0 - 8x(a^2 + a_2) = 0 \quad \text{and} \quad a_4 = (a_2/2)^2 - q_4(1/2)^4.$$  

From these equations we get

$$q_1 = 0, \quad q_3 = 0, \quad a_2 = q_2/2, \quad a_4 = q_2^2/16 - q_4/4.$$  

With $a_2 = 2\delta$ and $a_4 = \epsilon$ we have

$$P_2(x) = x^2 + 2\delta \quad \text{and} \quad Q(x) = x^4 + 4\delta \cdot x^2 + 4(\delta^2 - \epsilon).$$

At the signature cusp we have $\delta^2 = \epsilon$. Hence $Q$ has a double zero at the origin in this case. At the $\hat{A}$ cusp we have $\epsilon = 0$, hence $Q$ has two double zeroes.

For $N = 3$ we have:

$$\begin{align*}
(4x^3 + 3q_1x^2 + 2q_2x + q_3)(3x + 2a_1) \\
+ 6(x^4 + q_1x^3 + q_2x^2 + q_3x + q_4) - 18(x^4 + a_1x^3 + a_3x) = 0
\end{align*}$$

In this case we get the equations

$$a_1 = 3/2 \cdot q_1, \quad q_2 = -3/4 \cdot q_1^2, \quad a_2 = (2 \cdot q_3 - q_2^2)/4, \quad q_4 = -q_1q_3/2, \quad a_6 = (2 \cdot q_3 - q_2^2)^2/64.$$  

The two homogeneous equations satisfied by the coefficients $q_1$ through $q_4$ determine a curve $C_N$ in the weighted projective space with the weighted homogeneous coordinates $q_1$ through $q_4$, $q_i$ being of weight $i$. Each elliptic curve with distinguished primitive $N$-division point gives rise to a point on this modular curve $C_N$. If one parametrizes such elliptic curves by $\tau \in \Gamma_1(N) \backslash \mathbb{H}$ (cf. Appendix I, §7), then this mapping is simply given by $(q_1(\tau) : \ldots : q_4(\tau))$; this is well-defined since $q_i$ is a modular form of weight $i$ and the coordinates are weighted homogeneous. The modular curve is in general not irreducible, but the extension of the mapping to $\overline{\Gamma_1(N)} \backslash \mathbb{H}$ is surjective on individual components for dimensional reasons, which then parametrize our lattices.
Now each elliptic curve with an $N$-division point is also a curve with an $N \cdot d$-division point. What happens to the polynomials $P_N$, and how does the embedding $\iota$ of the corresponding modular curves look?

We consider the differential equation

$$c^{-N} \cdot P_N(\xi) = \tilde{T}_N(\eta).$$

In order to bring it to the form

$$c^{-dN} \cdot P_dN(\xi) = \tilde{T}_dN(\eta),$$

we must apply the polynomial $\tilde{T}_d$ (it follows immediately from the definition of the Chebyshev polynomials that $\tilde{T}_d(\tilde{T}_N) = \tilde{T}_dN$). We therefore obtain

$$P_{dN} = c^{dN} \cdot \tilde{T}_d(c^{-N} \cdot P_N).$$

This polynomial $P_{dN}$ is again almost-Chebyshev, and satisfies

$$Q \cdot (P_{dN}'/\omega)^2 = N^2 \cdot (P_{dN}^2 - 4c^{2dN})$$

with the same polynomial $Q$ as in the corresponding equation for $P_N$. For the polynomial $Q$ it is immediately clear that it does not change when an $N$-division point is re-interpreted as a $dN$-division point, i.e. on the modular curve $C_N$ the embedding into $C_{dN}$ is simply the inclusion of some components.

**Example:** For $N = 4$ the equations for $Q$ are given by

$$q_3 = -\frac{3}{8} \cdot q_1(q_1^2 + 4q_2),$$
$$q_1q_4 = \frac{1}{64} \cdot q_1(4q_2 + 5q_1^2)(4q_2 + q_1^2).$$

These equations encompass the case $N = 2$ ($q_1, q_2 = 0$). For $q_1 \neq 0$, $q_1$ and $q_2$ are arbitrary while $q_3$, $q_4$ depend on $q_1$, $q_2$.

The modular curve $C_N$ has in general many irreducible components; those which belong to an elliptic curve with a primitive $N$-division point are not in the image of an embedding as above. Since for a prime $N = p$ all $N$-division points are primitive, this should be the entire modular curve. Hence for a prime there should be only one component.

The map from $\Gamma_1(N) \setminus \mathbb{H}$ to $C_N$ can be extended to the cusps of $\Gamma_1(N)$. What does the differential equation at the cusps look like?

One of the values of the genus at the cusps is the normalized $\chi_y$-genus $\chi_y(X)/(1 + y)^{\dim X}$, where $-y$ must be an $N$-th root of unity different from $1$.
Hence the Todd genus $\chi_0(X)$ never arises. However, this is the only genus which is invariant under all birational transformations. For we have

$$\chi_0(X) = \sum_{q=0}^{\dim X} (-1)^q h^{0,q} = \sum_{q=0}^{\dim X} (-1)^q h^{q,0}$$

when $X$ is Kähler, and the numbers $h^{0,q}$ are birational invariants (including the geometric genus $h^{\dim X,0}$). Hence $\chi_0$ is invariant under birational transformations. Since in the cobordism ring $\Omega \otimes \mathbb{Q}$ each manifold $X$ is equal to a sum of products of projective spaces, which in turn is birationally equivalent to a multiple of $P_1(C)^{\dim X}$, each genus with this property is determined by its value on $P_1(C)$, hence is a multiple of $\chi_0$.

The power series

$$f(z) = \frac{1+y}{1+ye^{-z}} \cdot (1-e^{-z})$$

belonging to the normalized $\chi_y$-genus satisfies the differential equation

$$f'(z) = \left(1 - \frac{1}{1+y} f(z)\right) \cdot \left(1 + \frac{y}{1+y} f(z)\right).$$

If we bring the differential equation to our form, then with $c = \sqrt{-1}$ we have:

$$c^{-1} \cdot \left(\frac{f'}{f} + \frac{1-y}{1+y}\right) = (cf)^{-1} + cf$$

$$\Rightarrow P_1(x) = x + \frac{1-y}{1+y}.$$

But in this differential equation the coefficient of $f'/f$ is non-zero. We return to the embedding $i$ of modular curves. What follows for it from our condition $\alpha_{N-1} = 0$? The formula for $P_{dN}$ yields

$$P_{dN}(0) = e^{dN} \cdot \tilde{T}_d \left(c^{-N} \cdot P_N(0)\right) \cdot c^{-N} \cdot P_N(0).$$

So if $P_N'(0)$ is zero, this remains true for $P_{dN}'(0)$; if $P_N'(0)$ is not zero, then $c^{-N} \cdot P_N(0)$ must be a zero of $\tilde{T}_d$. In the differential equation of the normalized $\chi_y$-genus we have $N = 1$ and $c = \sqrt{-1}$. This forces $-y$ to be a $d$-th root of unity (check this!). Then we have

$$P_d = e^{d \frac{\pi i}{d}} \left(c^{-1} \left(x + \frac{1-y}{1+y}\right)\right),$$
i.e. \( P_d \) is essentially a Chebyshev polynomial. Hence the value at the critical point 0 is the same as at the other critical points, \( a_0^2 = 4a_{2d} \). In addition, we find the polynomial \( Q \) to be

\[
Q(x) = x^2 \left( (x + \frac{1-y}{1+y})^2 - 4c^2 \right) = x^2 \left( x^2 + 2\frac{1-y}{1+y}x + 1 \right);
\]

in particular, we have \( q_3, q_4 = 0 \), i.e. \( Q \) has a double zero at \( x = 0 \). We have therefore handled one kind of cusp.

For the derivation of the differential equation we have always assumed that \( c \neq 0 \), hence also \( a_{2N} \neq 0 \). If now \( a_{2N} = 0 \), i.e. apart from the origin only the critical value zero appears, then it follows by taking into account the other conditions on the coefficients \( a_r \) that the \( N \)-fold covering has only two branch points and the roots are rational. The genera which now arise are \( \chi(X, K^{k/N}) \) for \( 0 < k < N \). The corresponding power series is

\[
Q(x) = \frac{x}{1-e^{-2\pi i}} \cdot e^{-\frac{2\pi i}{N}} x
\]

\[
\Rightarrow f(x) = (1 - e^{-\pi i}) \cdot e^{\frac{2\pi i}{N}} x.
\]

What differential equation does \( f(x) = (1 - e^{-\pi i}) \cdot e^{\frac{2\pi i}{N}} x \) satisfy?

\[
e^{\frac{2\pi i}{N}} x = \left( \frac{N-k}{N} \right) \cdot f + Nf'
\]

\[
e^{-\frac{2\pi i}{N}} x = \frac{-kf + Nf'}{N},
\]

\[
\left( e^{\frac{2\pi i}{N}} x \right)^{N-k} \cdot \left( e^{-\frac{2\pi i}{N}} x \right)^k = 1
\]

\[
\Rightarrow \left( \frac{f'}{f} + \frac{N-k}{N} \right)^{N-k} \cdot \left( \frac{f'}{f} - \frac{k}{N} \right)^k = \frac{1}{f^N}.
\]

One easily concludes that in fact we have \( a_{N-1} = 0 \). Apart from the origin there are now two critical points, an \( (N - k - 1) \)-fold one at \( k/N \) and a \( (k - 1) \)-fold one at \( k/N - 1 \), both with the critical value 0. The polynomial \( Q \) is then

\[
Q(x) = (x - k/N)^2 \cdot (x - (k/N - 1))^2,
\]

so it has two double zeroes. In this case, the functions \( f'/f \) and \( f \) parametrize an \( N \)-sheeted covering of the Riemann sphere having these two branch points.

We have therefore found an interpretation of the modular curve which parametrizes elliptic curves with a non-zero \( N \)-division point by almost-Chebyshev polynomials (for a more detailed discussion of this relation between elliptic curves and almost-Chebyshev polynomials we refer to Appendix IV). If \( N = p \) is a prime, then this curve has only one component. The entire family of elliptic curves then forms an elliptic surface, which is known as a Shioda surface. Over each point of the modular curve lies an elliptic curve in the surface; over the points of the modular curve corresponding to the cusps of \( \Gamma_1(N) \)
the elliptic curves degenerate. For $p > 3$, the $\chi(X, K^{k/p})$-genus yields a rational curve with a double point, the double point yielding precisely the two branch points. For the $\chi_y$-genus the elliptic curve degenerates to a cycle of $p$ rational curves. These possess a natural involution. Dividing by the involution, we then have $(p + 1)/2$ components. These are precisely represented by the genera. For $-y$ is permitted to run through all primitive $p$-th roots of unity, but $y$ and $1/y$ yield the same genus.

Exercise: Calculate the Euler number of this elliptic surface.
8 A divisibility theorem for elliptic genera

8.1 The theorem of Ochanine

In this chapter we will use the (cf. [AtHi59b])

**Theorem:** Let $W$ be the complex extension of a real vector bundle (hence $W \cong W^*$) over a compact, oriented, differentiable spin manifold $M$ with $\dim M \equiv 4 \ (8)$. Then $\hat{A}(M, W) \in 2\mathbb{Z}$.\[\Box\]

**Remark:** For a complex manifold $X$ of dimension $d$, we have

$$\hat{A}(X, W) = \chi(X, K^{1/2} \otimes W) = \sum_{i=0}^{d} (-1)^i \dim H^i(X; K^{1/2} \otimes W).$$

We may transform these summands by Serre duality ($\dim X = d$):

$$H^i(X; K^{1/2} \otimes W) \cong H^{d-i}(X; K \otimes K^{-1/2} \otimes W^*)$$

$$\cong H^{d-i}(X; K^{1/2} \otimes W^*)$$

$$\cong H^{d-i}(X; K^{1/2} \otimes W).$$

We therefore see that modulo 2 all summands apart from the middle one ($i = d/2$) cancel. Now Serre duality is given by a bilinear form, which is skew-symmetric for odd $i = d/2$. Therefore $H^{d/2}(X; K^{1/2} \otimes W)$ must have an even dimension.

For the proof of the theorem in the real case, one uses the Dirac operator and the Atiyah-Singer index theorem.

Now we want to discuss the following (cf. [Oc81])

**Theorem (Ochanine):** Let $M$ be a compact, oriented, differentiable spin manifold with $\dim M \equiv 4 \ (8)$. Then we have:

$$\text{sign} (M) \equiv 0 \ (16).$$

We shall give the proof of the theorem in the next section.

**Remark:** Since in dimension four only the Pontrjagin number $p_1$ exists, in this case all genera differ from one another by a constant factor; in particular (cf. section 6.4)

$$\text{sign} (M) = -8 \cdot \hat{A}(M).$$
Using the above theorem on twisted $A$-genera (with $W$ a trivial line bundle), we obtain the theorem of Ochanine in dimension four. Rohlin proved this by different methods in 1950. The result is sharp in dimension four, since the $K3$-surface has signature 16.

For $k \geq 2$ we obtain by the plumbing construction a topological manifold $M^{4k}$ with intersection form $E_8$. The manifold therefore has signature 8. In addition it is $(2k - 1)$-connected, hence all its cohomology groups vanish in dimensions below $2k$. Following Thom and Wu, the Stiefel-Whitney classes can also be defined for topological manifolds (cf. [AtHi61a]). In our case, we have $w_1(M) = w_2(M) = 0$, since there is no cohomology in dimensions 1 and 2. If this manifold had a differentiable structure, all conditions of the above theorem would be satisfied, hence the signature would be at least 16. We therefore conclude that $M$ has no differentiable structure, and on the other hand that the theorem of Ochanine actually makes use of the differentiable structure. As we have seen, the theorem cannot be rescued for topological manifolds. We shall nevertheless investigate this case further. On the cohomology ring of a topological manifold $M$ of dimension $n$ there exist natural cohomology operations (cf. [StEp62]), the so-called Steenrod squares, with:

1) $Sq^i : H^i(M; \mathbb{Z}/2\mathbb{Z}) \to H^{i+i}(M; \mathbb{Z}/2\mathbb{Z})$,
2) $Sq^0 = \text{id}$,
3) $Sq^i(x) = x^2$ for $x \in H^i(M; \mathbb{Z}/2\mathbb{Z})$,
4) $Sq^i(x) = 0$ if $x \in H^i(M; \mathbb{Z}/2\mathbb{Z})$ with $j < i$,
5) $Sq^i(xy) = \sum_{j=0}^{i} Sq^j(x) \cdot Sq^{i-j}(y)$.

In addition there is a cohomology class $U_i \in H^i(M; \mathbb{Z}/2\mathbb{Z})$ with $Sq^i(x) = U_i \cdot x$ for $x \in H^{n-i}(M; \mathbb{Z}/2\mathbb{Z})$.

The Stiefel-Whitney classes can also be defined for topological manifolds, and we then have:

$$w = Sq(U),$$

i.e.

$$1 + w_1 + \cdots = Sq^0(1 + U_1 + \cdots) + Sq^1(1 + U_1 + \cdots) + \cdots.$$

For the first three classes this means:

$$w_1 = Sq^1(1) + Sq^0(U_1) = U_1,$$

$$w_2 = Sq^2(1) + Sq^1(U_1) + Sq^0(U_2) = U_1^2 + U_2,$$

$$w_3 = Sq^3(1) + Sq^2(U_1) + Sq^1(U_2) + Sq^0(U_3)$$

$$= Sq^1(U_2) + U_3.$$

More is implied by our assumptions $w_1, w_2 = 0$. For one obtains the odd Stiefel-Whitney classes $w_{2i+1}$ as the modulo 2 reduction of the image of $w_{2i}$ under the Bockstein operator for the coefficient sequence

$$0 \to \mathbb{Z} \xrightarrow{2} \mathbb{Z} \to \mathbb{Z}/2\mathbb{Z} \to 0.$$
Since we have $w_2 = 0$, it follows that also $w_3 = 0$. As we have already seen, these three Stiefel-Whitney classes are zero if and only if $U_1$, $U_2$ and $U_3$ vanish, that is the Steenrod squares $Sq^1$, $Sq^2$ and $Sq^3$ are identically zero in codimensions 1, 2 and 3, resp. We shall now exploit this in order to learn something about the intersection form of the manifold, which is defined on the integral lattice of the cohomology in the middle dimension. For this we make use of the so-called Adem relations which are general relations on the Steenrod squares. Two special cases read (with $i \geq 1$ and coefficients modulo 2):

$$Sq^2 Sq^{4i} = \binom{4i-2}{2} \cdot Sq^{4i+2} + \binom{4i-2}{0} \cdot Sq^{4i+2} Sq^1$$

$$= Sq^{4i+2} + Sq^{4i+1} Sq^1,$$

$$Sq^3 Sq^{4i-1} = \binom{4i-2}{3} \cdot Sq^{4i+2} + \binom{4i-3}{1} \cdot Sq^{4i+1} Sq^1$$

$$= Sq^{4i+1} Sq^1,$$

$$\Rightarrow Sq^{4i+2} = Sq^3 Sq^{4i} + Sq^3 Sq^{4i-1}.$$

The right side is zero when applied to cohomology classes of codimension $4i + 2$, since $Sq^2$ and $Sq^3$ vanish in codimension 2 resp. 3. Therefore $Sq^{4i+2}$ is zero in codimension $4i + 2$.

**Definition:** The intersection form of $M^{4n}$ is called even if

$$x^2 [M] \equiv 0 \quad (2) \quad \text{for all } x \in H^{2n}(M; \mathbb{Z}).$$

As we have seen above, we obtain for any $8k + 4$-dimensional topological manifold with vanishing $w_1$ and $w_2$ that $x \cdot x = Sq^{4k+2}(x) = 0$ for $x \in H^{4k+2}(M; \mathbb{Z}/2\mathbb{Z})$. So our intersection form is even. By Poincaré duality it is always unimodular, i.e. nonsingular. Now the signature of an even unimodular quadratic form is always divisible by 8. For topological manifolds with $w_1 = w_2 = 0$, Ochanine’s theorem therefore still holds in the weaker form

$$\text{sign} (M^{8k+4}) \equiv 0 \quad (8).$$

Just as the Stiefel-Whitney classes $w_j$ can be expressed in terms of the $U_i$ by means of the Steenrod squares, one can express the $U_i$ in terms of the $w_j$, indeed as polynomials in the $w_j$. We shall consider these polynomials in greater detail (cf. [Wu50]):

**Theorem (Wu):** There exists a weighted homogeneous polynomial $U_n(w_1, \ldots, w_n)$ of degree $n$ where $w_i$ has degree $i$, such that for each compact topological manifold $M^{2n}$ with Stiefel-Whitney classes $w_i$ there holds

$$x^2 = (x \cdot U_n(w_1, \ldots, w_n)) \quad \text{for all } x \in H^n(M; \mathbb{Z}/2\mathbb{Z}).$$
The polynomials $U_i$ form a multiplicative sequence in the Stiefel-Whitney classes, having the characteristic power series

$$1 + \sum_{i=0}^{\infty} x^i = \frac{2x}{1 - e^{-2x}} \quad (2).$$

The power series on the right side yields precisely the Todd polynomials, up to a factor $2^i$ in front of $x^i$. We therefore have

$$U_n \equiv 2^n \cdot T_n(w_1, \ldots, w_n) \quad (2).$$

The factor $2^n$ is needed to cancel the powers of 2 in the denominator of the coefficients of the power series $x/(1 - e^{-x})$.

**Example:**

$$T_2 = \frac{c_2 + c_1^2}{12} \quad \Rightarrow \quad U_2 = w_2 + w_1^2,$$

$$T_3 = \frac{c_1c_2}{24} \quad \Rightarrow \quad U_3 = w_1w_2,$$

$$T_4 = \frac{-c_4 + c_3c_1 + 3c_2^2 + 4c_2c_1^2 - c_1^4}{720} \quad \Rightarrow \quad U_4 = w_4 + w_3w_1 + w_2^2 + w_1^4.$$

Hence we see that, when $w_1, w_2 = 0$, the polynomial $U_2$ vanishes. Since in addition $w_3 = 0$, we also have

$$U_6 = w_4w_2 + w_4w_1^2 + w_3^2 + w_3w_2w_1 + w_3w_1^2 + w_2^2w_1^2 = 0.$$

Here we are fortunate, since theoretically $w_6$ could also appear as a term in $U_6$. However, the coefficient of $c_6$ in $T_6$ is even. As we have seen, multiplication by the polynomial $U_{4i+2}$ on the cohomology in codimension $4i + 2$ of any manifold with $w_1, w_2, w_3 = 0$ is the zero mapping. Since this multiplication originates from a non-degenerate pairing of the corresponding cohomology groups, $U_{4i+2}$ is zero in the cohomology ring of every such manifold. Nevertheless, as a polynomial $U_{4i+2}$ need not vanish modulo the indeterminates $w_1, w_2, w_3$.

**Example:**

$$U_{10} \equiv w_5^2 \quad (w_1, w_2, w_3), \quad U_{14} \equiv w_4w_5^2 \quad (w_1, w_2, w_3).$$
8.2 Proof of Ochanine's theorem

Having already formulated the theorem in the last section, we shall now prove it. For this we shall recall once more some of the general theory of elliptic genera of level \( N \).

Let \( L = 2\pi i (\mathbb{Z} \tau + \mathbb{Z}) \subset \mathbb{C} \) be a lattice, and let \( h \) be the elliptic function for this lattice with divisor \( (h) = N \cdot (0) - N \cdot (\alpha) \) and the normalization \( h(x) = x^N + \cdots \). Here \( \alpha \) is an \( N \)-division point of the lattice \( L \), which we take as \( \alpha = 2\pi i / N \). In addition, we have denoted by \( f \) the \( N \)-th root of \( h \), normalized by \( f(x) = x + \cdots \). For a complex manifold \( X \) of complex dimension \( d \), the elliptic genus \( \varphi_{N,\alpha} \) of level \( N \) is then given by

\[
\varphi_{N,\alpha}(X) = \left( \prod_{i=1}^{d} \frac{x_i}{f(x_i)} \right) [X].
\]

The power series \( f \) can be explicitly determined. With

\[
\Phi(\tau, x) = 2 \cdot \sinh (x/2) \cdot \prod_{n=1}^{\infty} \frac{(1 - q^n e^x)(1 - q^n e^{-x})}{(1 - q^n)^2}
\]

we have

\[
f(x) = \frac{\Phi(\tau, x)\Phi(\tau, -\alpha)}{\Phi(\tau, \tau - \alpha)}.
\]

The elliptic genus \( \varphi_{N,\alpha}(X) \) of \( X \) is a modular form of weight \( d \) on \( \Gamma_1(N) \) \( (\Gamma_1(N), \) in view of our choice of \( \alpha \). As the expansion of the elliptic genus at a \( \chi_y \)-cusp we obtained

\[
\chi_y(q, \mathcal{L}X) = \varphi_{N,\alpha}(X) \cdot \Phi(\tau, -\alpha)^d \cdot (-y)^{d/2}
\]

with \( -y = e^\alpha \). The normalization factor \( (e^{\alpha/2} \cdot \Phi(\tau, -\alpha))^{-1} \) is a modular form of weight 1 on \( \Gamma_1(N) \), up to \( 2N \)-th roots of unity. If \( 2N \) divides the dimension \( d \), then \( (e^{\alpha/2} \cdot \Phi(\tau, -\alpha))^{-d} \) is likewise a modular form of weight \( d \) (cf. section 7.4). Hence \( \chi_y(q, \mathcal{L}X) \) is a modular function on \( \Gamma_1(N) \) if \( 2N \mid d \).

We also have derived a product representation:

\[
\chi_y(q, \mathcal{L}X) = \prod_{i=1}^{d} \frac{1 + ye^{-x_i}}{1 - e^{-x_i}} \left( \prod_{n=1}^{\infty} \frac{1 + yq^n e^{-x_i}}{1 - q^n e^{-x_i}} \cdot \frac{1 + y^{-1}q^n e^{x_i}}{1 - q^n e^{x_i}} \right) [X]
\]

\[
= \chi_y \left( X, \bigotimes_{n=1}^{\infty} \Lambda_{yq^n} T^* \otimes \bigotimes_{n=1}^{\infty} S_{q^n} T^* \otimes \bigotimes_{n=1}^{\infty} \Lambda_{y^{-1}q^n} T \otimes \bigotimes_{n=1}^{\infty} S_{q^n} T \right)
\]

\[
= \chi_y(X) + \cdots.
\]

The representation in terms of the twisted \( \chi_y \)-genera follows once again from the formulas in section 1.5. The coefficients of \( q^l \) are therefore algebraic integers in the cyclotomic
field $\mathbb{Q}[y]$. For $y = 1$ one can combine the terms for $T$ and for $T^*$ and express them using $T_{2^c} = T \oplus T^*$. In order to arrive at our genus from this expansion, we must still divide by $\Phi(\tau, -\alpha)^d(-y)^{d/2}$. Now we have

$$\Phi(\tau, -\alpha)^d = (2 \cdot \sinh (-\alpha/2) \cdot \text{(integral q-expansion)})^d$$

$$= \left(e^{-\alpha/2} - e^{\alpha/2}\right)^d \cdot \text{(integral q-expansion)}$$

$$= e^{-\alpha/2} \cdot \left(1 - e^{\alpha}\right)^d \cdot (1 - y)^{d/2} \cdot \text{(integral q-expansion)},$$

where "integral q-expansion" always starts with $1 + O(q)$. Hence it is invertible in $\mathbb{Z}[[q]]$ and we have

$$\varphi_{N, \alpha}(X) = \frac{\text{(integral q-expansion)}}{(1 + y)^d}.$$

How does the expansion look at one of the other cusps?

Instead of expanding the genus at another cusp, we can also change the $N$-division point (cf. Appendix I, §6). We now choose $\alpha = 2\pi i k \tau / N$ with $0 < k < N$. The power series $f$ then takes the form

$$f(x) = \frac{\Phi(\tau, x) \Phi(\tau, -\alpha)}{\Phi(\tau, x - \alpha)} \cdot e^{(k/N)x}$$

and for the genus we obtain:

$$\varphi_{N, \alpha}(X) = \left(\prod_{i=1}^d \left(1 - \frac{1 - q^{k/N} e^{-x_i}}{1 - q^{k/N}} \cdot e^{-x_i}\right) \cdot \prod_{n=1}^\infty \frac{(1 - q^{n+k/N} e^{-x_i})(1 - q^{n-k/N} e^{-x_i})(1 - q^n)^2}{(1 - q^{n+k/N})(1 - q^{n-k/N})(1 - q^n)}\right)[X].$$

In this expression $q^{1/N}$ appears: $\varphi_{N, \alpha}(X)$ is a modular form on $\Gamma_1(N)$. In order to obtain a modular form on $\Gamma_1(N)$ we must replace $q$ by $q^N$; the $q$-expansion of this modular form $\tilde{\varphi}_{N, \alpha}(X)$ has integral coefficients:

$$\tilde{\varphi}_{N, \alpha}(X) = (\text{Norm.})$$

$$\cdot \chi \left(X, K^k/N \otimes \bigotimes_{n \equiv k (N)} \Lambda_T T^* \otimes \bigotimes_{n=1}^\infty S_q T^* \otimes \bigotimes_{n \equiv -k (N)} \Lambda_T T \otimes \bigotimes_{n=1}^\infty S_q T\right).$$

Here the normalization factor "Norm." has integral coefficients, and the integrality of the coefficients of the Riemann-Roch expression follows from that of $\chi(X, K^k/N \otimes W)$ for
8.2 Proof of Ochanine's theorem

Therefore our genus $\varphi_{N,\alpha}$ has an integral $q$-expansion for $\alpha = 2\pi ik\tau/N$, provided that $c_1$ is divisible by $N$.

We now specialize these considerations to the elliptic genera of level two. Let $X$ be an oriented differentiable manifold of dimension $4k$. The elliptic genus of level two then yields a modular form of weight $2k$ on $\Gamma_1(2) = \Gamma_0(2)$. There are two cusps. At one cusp (the signature) the expansion is integral up to the factor $2^{-2k}$ (for $d = 2k$ and $y = 1$), at the other cusp (the $A$-genus) the $q$-expansion is integral if $c_1 \equiv 0 \pmod{2}$, i.e. $w_2 = 0$. The coefficients of this $q$-expansion are twisted $A$-genera $A(X, W)$. The bundles $W$ which occur are complex bundles associated to $\mathcal{T}_C$, hence satisfy $W^* \cong W$.

For this genus we began with the differential equation

$$f'^2 = 1 - 2\delta \cdot f^2 + \varepsilon \cdot f^4.$$  

From the product representation of $f$ at the signature cusp one can easily determine the coefficients of $f'(x)/f(x)$, and then use the differential equation to obtain the following formulas for $\delta$ and $\varepsilon$ (cf. Appendix I, §§3,4):

$$\delta = 1/4 + 6 \sum_{n=1}^{\infty} \sum_{d|n} d \cdot q^n,$$

$$\varepsilon = 1/16 + \sum_{n=1}^{\infty} \sum_{d|n} (-1)^d d^3 \cdot q^n.$$

If one expands $f$ at the other cusp, one must obviously also do this for $\delta$ and $\varepsilon$ in the differential equation. We shall denote by a tilde the conjugate expansion for $\Gamma_0(2)$ at the other cusp,

$$\tilde{f}'^2 = 1 - 2\tilde{\delta} \cdot \tilde{f}^2 + \tilde{\varepsilon} \cdot \tilde{f}^4.$$  

Under this passage, we must replace $\tau$ by $-1/\tau$ and then $\tau$ by $2\tau$, in order to arrive at the modular group $\Gamma_0(2)$. We then have (again, cf. Appendix I, §§3,4):

$$\tilde{\delta} = -1/2 \cdot \delta = -1/8 - 3 \sum_{n=1}^{\infty} \sum_{d|n} d \cdot q^n,$$

$$\tilde{\varepsilon} = \frac{\delta^2 - \varepsilon}{4} = \sum_{n=1}^{\infty} \sum_{d|n} d^3 \cdot q^n.$$  

Now each modular form on $\Gamma_0(2)$ is a homogeneous polynomial in $\delta$ and $\varepsilon$, hence also a polynomial in $8\tilde{\delta}$ and $\tilde{\varepsilon}$:

$$\tilde{\varphi}(X^{4k}) = \sum_{a,b} c_{a,b} \cdot (8\tilde{\delta})^a \cdot \tilde{\varepsilon}^b = P(8\tilde{\delta}, \tilde{\varepsilon}).$$
If \( w_2(X) = 0 \), we know that \( \hat{\varphi}(X) \) has an integral \( q \)-expansion, and then the coefficients \( c_{a,b} \) must likewise be integral (proceed by induction, noting that \( 8\delta = -1 + \cdots \) and \( \hat{\varepsilon} = q + \cdots \)), hence

\[
\hat{\varphi}(X^{4k}) \in \mathbb{Z}[8\delta, \hat{\varepsilon}]
\]

\[
\Rightarrow \quad \varphi(X^{4k}) \in \mathbb{Z}[8\delta, \varepsilon].
\]

Now at the signature cusp \( 2^{2k} \cdot \varphi(X) \) is integral,

\[
\text{sign } (q, LX) = \varphi(X) \cdot 2^{2k} \cdot (\text{integral } q\text{-expansion})
\]

\[
= 2^{2k} \cdot P(8\delta, \varepsilon) \cdot (\text{integral } q\text{-expansion})
\]

\[
= P(32\delta, 16\varepsilon) \cdot (\text{integral } q\text{-expansion}),
\]

\[
32\delta = 8 \cdot (1 + 24q \cdot (\cdots)),
\]

\[
16\varepsilon = 1 + 16q \cdot (\cdots).
\]

If our manifold has dimension \( 4k \) with \( k \) odd, then the polynomial \( P \) is divisible by \( 32\delta \), since otherwise the weight could not be \( 2k \). Hence all the coefficients of the modular function on the left side are divisible by \( 8 \):

\[
\text{sign } (q, LX) \equiv 0 \ (8).
\]

We are now just a factor of \( 2 \) away from Ochanine's theorem. By the theorem at the start of section 8.1, the expansion at the \( \hat{A} \)-cusp is not only integral, indeed its coefficients are all even. It follows at once that all the coefficients \( c_{a,b} \) of the polynomial \( P \) must likewise be even. We conclude that

\[
\text{sign } (q, LX) \equiv 0 \ (16).
\]

In particular this holds for the constant term, the signature of \( X \).
Appendix I: Modular forms

by Nils-Peter Skoruppa, Max-Planck-Institut für Mathematik, Bonn

1 Fundamental concepts

Let \( \mathfrak{h} = \{ \tau \in \mathbb{C} \mid \text{Im}(\tau) > 0 \} \) be the upper half-plane of the complex numbers. The group \( \text{SL}_2(\mathbb{R}) \) acts on \( \mathfrak{h} \) by
\[
\begin{pmatrix} a & b \\ c & d \end{pmatrix} \tau := \frac{a \tau + b}{c \tau + d} \quad \text{for} \quad A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{SL}_2(\mathbb{R}) \quad \text{and} \quad \tau \in \mathfrak{h}.
\]
This action is the restriction to \( \mathfrak{h} \) of the natural action of \( \text{SL}_2(\mathbb{R}) \) on \( \mathbb{P}^1(\mathbb{C}) \), if one regards \( \mathfrak{h} \) as a subset of \( \mathbb{P}^1(\mathbb{C}) \) via \( \tau \mapsto [\tau : 1] \). Because \( \text{Im}(A\tau) = \text{Im}(\tau)/|c\tau + d|^2 \), \( \mathfrak{h} \) is in fact invariant under \( \text{SL}_2(\mathbb{R}) \).

**Remark:** This action factorizes to an action of the group \( \text{PSL}_2(\mathbb{R}) = \text{SL}_2(\mathbb{R})/\{\pm 1\} \); \( \text{PSL}_2(\mathbb{R}) \) is isomorphic to the group of biholomorphic transformations of \( \mathfrak{h} \).

For a subgroup \( \Gamma \subset \text{SL}_2(\mathbb{R}) \), \( \Gamma \backslash \mathfrak{h} \) becomes a topological space by means of the quotient topology. If \( \Gamma \) is a discrete subgroup, then a unique complex structure exists on \( \Gamma \backslash \mathfrak{h} \) so that the natural projection \( \pi : \mathfrak{h} \rightarrow \Gamma \backslash \mathfrak{h} \) is holomorphic.

Each compact Riemann surface of genus greater or equal to 2 can be obtained in that way. For if \( X \) is a Riemann surface and \( \tilde{X} \) its universal covering, then by the Riemann mapping theorem \( \tilde{X} \) is isomorphic to either \( \mathbb{P}^1(\mathbb{C}), \mathbb{C} \) or \( \mathfrak{h} \); Therefore we have \( X \cong \mathbb{P}^1(\mathbb{C}) \), or \( X \cong \mathbb{C}/L \) for a lattice \( L \) in \( \mathbb{C} \) (and \( X \) has genus 1), or \( X \cong \Gamma \backslash \mathfrak{h} \) for suitable \( \Gamma \subset \text{SL}_2(\mathbb{R}) \) (and \( X \) has genus greater or equal to 2). In the last two cases \( L \), resp. \( \Pi : = \Gamma/(\{\pm 1\} \cap \Gamma) \) is isomorphic to the group of covering transformations of the covering \( \tilde{X} \rightarrow X \), i.e. is isomorphic to \( \pi_1(X) \).

**Examples:** Examples of discrete subgroups of \( \text{SL}_2(\mathbb{R}) \) are provided by \( \text{SL}_2(\mathbb{Z}) \) and each subgroup \( \Gamma \subset \text{SL}_2(\mathbb{Z}) \). In particular, for \( n \in \mathbb{N} \) we define the following subgroups
\[
\begin{align*}
\Gamma_0(N) := & \{ A \in \text{SL}_2(\mathbb{Z}) \mid A \equiv \begin{pmatrix} \ast & \ast \\ 0 & \ast \end{pmatrix} (N) \}, \\
\Gamma^0(N) := & \{ A \in \text{SL}_2(\mathbb{Z}) \mid A \equiv \begin{pmatrix} \ast & 0 \\ 0 & \ast \end{pmatrix} (N) \}, \\
\Gamma_1(N) := & \{ A \in \text{SL}_2(\mathbb{Z}) \mid A \equiv \begin{pmatrix} 1 & \ast \\ 0 & 1 \end{pmatrix} (N) \}, \\
\Gamma(N) := & \{ A \in \text{SL}_2(\mathbb{Z}) \mid A \equiv \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} (N) \}.
\end{align*}
\]
The group \( \Gamma(N) \) is called the principal congruence subgroup of level \( N \). The following sequence is exact:
\[
1 \rightarrow \Gamma(N) \hookrightarrow \text{SL}_2(\mathbb{Z}) \twoheadrightarrow \text{SL}_2(\mathbb{Z}/N\mathbb{Z}) \twoheadrightarrow 1,
\]
\[
A \mapsto A \mod N.
\]
Hence $\Gamma(N)$ is a normal subgroup in $\text{SL}_2(\mathbb{Z})$, and has finite index in $\text{SL}_2(\mathbb{Z})$ (so therefore do $\Gamma_0(N) \supset \Gamma_1(N) \supset \Gamma(N)$ etc.). In terms of the Euler $\varphi$-function

$$\varphi(N) := N \cdot \prod_{\substack{p \mid N \ \text{prime}}} (1 - p^{-1})$$

and

$$\psi(N) := N \cdot \prod_{\substack{p \mid N \ \text{prime}}} (1 + p^{-1})$$

we have more precisely:

$$[\text{SL}_2(\mathbb{Z}) : \Gamma(N)] = N^3 \cdot \prod_{\substack{p \mid N \ \text{prime}}} (1 - p^{-2}) = N \cdot \varphi(N) \cdot \psi(N),$$

(1)

$$[\text{SL}_2(\mathbb{Z}) : \Gamma_1(N)] = N^2 \cdot \prod_{\substack{p \mid N \ \text{prime}}} (1 - p^{-2}) = \varphi(N) \cdot \psi(N),$$

(2)

$$[\text{SL}_2(\mathbb{Z}) : \Gamma_0(N)] = N \cdot \prod_{\substack{p \mid N \ \text{prime}}} (1 + p^{-1}) = \psi(N).$$

(3)

For $k \in \mathbb{Z}$, $\text{SL}_2(\mathbb{R})$ acts to the right on functions $f : \mathbb{H} \rightarrow \mathbb{C}$: For $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{SL}_2(\mathbb{R})$ and $k \in \mathbb{Z}$ we define

$$(f|_k A)(\tau) := (cr + d)^{-k} \cdot f(A\tau).$$

That $(f, A) \mapsto f|_k A$ in fact defines an action follows from the following cocycle relation: With $A A' = A''$ we have

$$(cA'\tau + d) \cdot (c'\tau + d') = (c''\tau + d''),$$

where $c, d, c', d'$ etc. denote the lower entries of $A, A'$ etc.

**Remark:** $\text{SL}_2(\mathbb{Z})$ acts transitively on $P_1(\mathbb{Q}) \subset P_1(\mathbb{C})$. For a subgroup $\Gamma \subset \text{SL}_2(\mathbb{Z})$ of finite index, the orbits with respect to the action of $\Gamma$ on $P_1(\mathbb{Q})$ are called the cusps of $\Gamma$, or the cusps of $\Gamma \backslash \mathbb{H}$.

**Definition:** Let $k \in \mathbb{Z}$ and $\Gamma \subset \text{SL}_2(\mathbb{Z})$ be of finite index. A function $f : \mathbb{H} \rightarrow \mathbb{C}$ is called a modular form of weight $k$ on $\Gamma$ if:

(i) $f$ is holomorphic on $\mathbb{H}$,
(ii) $f|_k A = f$ for all $A \in \Gamma$,
(iii) for every $S \in \text{SL}_2(\mathbb{Z})$, $f|_k S$ has a Fourier expansion of the form:

$$(f|_k S)(\tau) = \sum_{n \geq 0} a_n \cdot e^{2\pi i n \tau / N}$$

(4)

for suitable $a_n$ and suitable $N \in \mathbb{N}$. 

I.1 Fundamental concepts

Let \( M_k(\Gamma) \) denote the complex vector space of all modular forms of weight \( k \) on \( \Gamma \).

Remarks:

1) Let \( f \) be a function on \( \mathcal{H} \) satisfying (i) and (ii). Then, for each \( S \in \text{SL}_2(\mathbb{Z}) \), \( f|_k S \) is invariant under \( S^{-1}\Gamma S \). Since \( S^{-1}\Gamma S \) has finite index in \( \text{SL}_2(\mathbb{Z}) \), there exists an \( N \in \mathbb{Z}, \ N > 0, \) such that \( (\begin{smallmatrix} 1 & N \\ 0 & 1 \end{smallmatrix}) S^{-1}\Gamma S = S^{-1}\Gamma S \), i.e. \( (\begin{smallmatrix} 1 & N \\ 0 & 1 \end{smallmatrix}) \in S^{-1}\Gamma S \). Therefore \( (f|_k S)(\tau + N) = (f|_k S)(\tau) \), so there exists a holomorphic mapping \( g : \{ t \in \mathbb{C} \mid 0 < |t| < 1 \} \to \mathbb{C} \) with the property \( (f|_k S)(\tau) = g(e^{2\pi i \tau/N}) \), i.e.

\[
(f|_k S)(\tau) = \sum_{n=-\infty}^{\infty} a_n \cdot e^{2\pi i n \tau/N}
\]

for suitable \( a_n \). Thus we see that the restriction in (iii) of the definition of modular forms only consists of the requirement that \( a_n = 0 \) for \( n < 0 \), and not in the condition that a Fourier expansion exists. The expansion (4) is called a Fourier expansion at the cusp \( \infty \).

2) Let \( f \) be a modular form of weight \( k \) on \( \Gamma \), let \( s = \infty \) for a suitable \( S \in \text{SL}_2(\mathbb{Z}) \) and \( f|_k S \) as in (4). Then one puts \( \text{ord}_s(f) := n_0/N \), where \( n_0 \) denotes the smallest integer with \( a_{n_0} \neq 0 \), and, for \( k \) even, one puts \( f(s) := a_0 \). The quantities \( f(s) \) and \( \text{ord}_s(f) \) are independent of the special choice of \( S \) and only depend on \( s \) modulo \( \Gamma \). For if \( \tau \in \Gamma \infty \), \( \infty \) = \( \tau \), then there exists a \( G \in \Gamma \) with \( G \cdot R = S \cdot (\begin{smallmatrix} \epsilon & n_1 \\ 0 & 1 \end{smallmatrix}) \). Therefore we have:

\[
(f|_k R)(\tau) = (f|_k GR)(\tau) = (f|_k S \cdot (\begin{smallmatrix} \epsilon & n_1 \\ 0 & 1 \end{smallmatrix}))(\tau) = \epsilon^k \cdot (f|_k S)(\tau + \epsilon n_1) = \epsilon^k \cdot \sum_{n \geq 0} a_n \cdot e^{2\pi i n \tau/N} \cdot e^{2\pi i n \tau/N}.
\]

Modular forms \( f \) which vanish at all cusps, i.e. which satisfy \( \text{ord}_s(f) > 0 \) for all \( s \in P_1(\mathbb{Q}) \), are called cusp forms. The space of cusp forms of weight \( k \) on \( \Gamma \) is denoted \( S_k(\Gamma) \).

3) As mentioned above, the space \( X := \Gamma \setminus \mathcal{H} \) can be given a complex structure so that \( \pi : \mathcal{H} \to \Gamma \setminus \mathcal{H} \) is holomorphic. By adjunction of the cusps \( \Gamma \setminus P_1(\mathbb{Q}) \) one can make \( X \) into a compact Riemann surface \( \bar{X} \). For even \( k \), the conditions (i) and (ii) correspond to the fact that there exists a holomorphic differential form \( \omega \) of weight \( k/2 \) on \( X \) with \( \pi^* \omega = f(\tau)(d\tau)^{k/2} \). Condition (iii) then implies that at the cusps \( \omega \) has at most a pole, whose order is bounded by \( k/2 \). In particular, for \( k = 2 \) and \( f \) a cusp form, the differential form \( \omega \) is holomorphic on all of \( \bar{X} \), and vice versa any holomorphic differential on \( \bar{X} \) can be so obtained.
Thus, one can interpret modular forms as sections of certain line bundles over $\bar{X}$; from general theorems on Riemann surfaces, the finite dimensionality of the spaces $M_k(\Gamma)$ then follows immediately (cf. [Sh71]). For $k = 2$, it follows from this point of view that the dimension of $S_2(\Gamma)$ is equal to the genus of $X$.

For general background on modular forms see, for example, [Sh71], [Se70], [Ap76], [Sch74] or [Gu62].

2 Examples of modular forms

2.1 Eisenstein series

Let $g : \mathfrak{h} \to \mathbb{C}$ be a mapping, then $f = \sum_{A \in \Gamma} g|_k A$ transforms formally as a modular form of weight $k$ on $\Gamma$. It naturally remains to investigate the convergence of such an expression. A series defined in this manner is certainly divergent if the stabilizer $\Gamma_g = \{ A \mid g|_k A = g \}$ of $g$ has infinite order (and $g \neq 0$). A better definition for $f$ is therefore in general:

$$f := \sum_{A \in \Gamma_g \backslash \Gamma} g|_k A.$$

For $g$ a constant function and $\Gamma = \text{SL}_2(\mathbb{Z})$ this construction yields, as an example, the so-called Eisenstein series:

$$E_k := \frac{1}{2} \sum_{A \in \left(\begin{smallmatrix} \ast & 0 \\ 0 & \ast \end{smallmatrix}\right) \backslash \text{SL}_2(\mathbb{Z})} 1|_k A. \quad (1)$$

Note that for $k$ odd $M_k(\text{SL}_2(\mathbb{Z})) = 0$, since any $f \in M_k(\text{SL}_2(\mathbb{Z}))$ satisfies $f = f|_k (-\text{id}) = (-1)^k f$. The same argument holds of course for any $\Gamma$ containing $-\text{id}$. Thus we can restrict to even $k$, and here one has:

**Theorem 2.1:** For $k > 2$ even, $E_k \in M_k(\text{SL}_2(\mathbb{Z}))$. More precisely, the sum $(1)$ is normally convergent on $\mathfrak{h}$, thus defines a holomorphic function on $\mathfrak{h}$, is invariant under $\text{SL}_2(\mathbb{Z})$ with respect to the "$|_k$"-action, and one has

$$E_k(\tau) = 1 + O(e^{2\pi i r}) \text{ for } \text{Im}(\tau) \to \infty.$$

**Proof:** To show that the series in $(1)$ is normally convergent, it suffices to show that it is absolutely and uniformly convergent in each region of the form $B$:
I.2 Examples of modular forms

From this it will also follow that:

\[
\lim_{\nu \to \infty} E_k(i \cdot \nu) = \frac{1}{2} \sum_{A \in \left( \frac{1}{0} \right) \setminus \text{SL}_2(\mathbb{Z})} \lim_{\nu \to \infty} (1 | kA)(i \cdot \nu) = 1.
\]

For the last identity note that \( \lim_{\nu \to \infty} (1 | kA)(i \cdot \nu) \) is different from 0, and then equal to 1, if and only if \( A \in \pm \left( \frac{1}{2} \frac{1}{2} \right) \). To prove the asserted convergence note first of all that two matrices \( A \) and \( A' \) lie in the same left coset with respect to \( \left( \frac{1}{0} \frac{1}{1} \right) \) if and only if their lower rows are equal. Thus we can write

\[
E_k(\tau) = \frac{1}{2} \sum_{c,d \in \mathbb{Z}} \frac{1}{(c\tau + d)^k}.
\]

Set

\[
\mu := \inf_{x^2 + y^2 = 1} |x\tau + y|^2.
\]

Then \( \mu \) is positive, since the continuous function \( (\tau, x, y) \mapsto |x\tau + y|^2 \) attains its minimum on the set of all \( (\tau, x, y) \) with \( \tau \in B \) and \( x^2 + y^2 = 1 \). Using this \( \mu \) one has for all \( c, d \in \mathbb{Z} \) and \( \tau \in B \) the inequality

\[
|c\tau + d|^2 \geq \mu(c^2 + d^2).
\]

Thus the sum in (2) is dominated by

\[
\mu^{-k/2} \sum_{c,d \in \mathbb{Z}} \frac{1}{(c^2 + d^2)^{k/2}},
\]

which in turn is dominated by

\[
\text{const} \cdot \int_{\mathbb{R}^2 \setminus \{0\}} \frac{dx \, dy}{(x^2 + y^2)^{k/2}} = \text{const} \cdot \int_0^\infty \int_0^{2\pi} \frac{r \, dr \, d\theta}{r^k} < \infty.
\]

We have \( M_{2k}(\text{SL}_2(\mathbb{Z})) = \text{C} \cdot E_{2k} \oplus S_{2k}(\text{SL}_2(\mathbb{Z})) \). This follows easily from the facts that \( E_{2k}(\infty) = 1 \) and \( \infty \) is the only cusp of \( \text{SL}_2(\mathbb{Z}) \) (i.e. \( \text{SL}_2(\mathbb{Z}) \) acts transitively on \( \mathcal{H}(\mathbb{Q}) \)).
2.2 Theta series

Definition: Let $k$ be even and let $L \subset \mathbb{R}^k$ be a lattice, i.e. there is a basis $(e_1, \ldots, e_k)$ of $\mathbb{R}^k$ so that $L = \mathbb{Z}e_1 + \cdots + \mathbb{Z}e_k$; assume that $L$ is integral and even, i.e. $x \cdot y \in \mathbb{Z}$ and $x^2 \in 2\mathbb{Z}$ for all $x, y \in L$. Here $x \cdot y$ denotes the standard scalar product on $\mathbb{R}^k$. The determinant of $L$ is defined by $\det(L) := \mathbb{H}(L_{\text{dual}}/L)$, where $L_{\text{dual}} = \{y \in \mathbb{R}^k \mid y \cdot L \subset \mathbb{Z}\}$. The level $N$ of $L$ is the smallest natural number $N$ for which $Ny^2 \in 2\mathbb{Z}$ for all $y \in L_{\text{dual}}$.

Definition: For a Dirichlet character $\chi$ modulo $N$ we define:

$M_k(\Gamma_0(N), \chi) := \{ f \in M_k(\Gamma_0(N)) \mid f|_k \left( \begin{smallmatrix} & a \\ \ell & \end{smallmatrix} \right) = \chi(d) \cdot f \text{ for all } \left( \begin{smallmatrix} & a \\ \ell & \end{smallmatrix} \right) \in \Gamma_0(N) \}.$

Let

$$\theta_L(\tau) := \sum_{x \in L} e^{\pi i \tau x^2} = \sum_{n=0}^{\infty} \# \{ x \in L \mid x^2/2 = n \} \cdot e^{2\pi i \tau n}.$$

Theorem 2.2: We have

$$\theta_L(\tau) \in M_{k/2} \left( \Gamma_0(N), \left( \frac{-1}{\cdot} \right)^{k/2} \det(L) \right),$$

where $(\cdot)$ denotes the Jacobi symbol.

For the proof the reader is referred to [Sch74] or [Og69].

Example:

$$\theta(\tau) := \sum_{x,y \in \mathbb{Z}} e^{2\pi i \tau (x^2+y^2)}$$

$$= \sum_{n=0}^{\infty} \# \{ (x,y) \in \mathbb{Z}^2 \mid x^2+y^2 = n \} \cdot e^{2\pi i \tau n}.$$

Here $\theta = \theta_L$ for $L = \sqrt{2} \cdot (\mathbb{Z} \times \mathbb{Z})$. We have $L_{\text{dual}} = \frac{1}{\sqrt{2}} \mathbb{Z} \times \frac{1}{\sqrt{2}} \mathbb{Z}$, $N = 4$, $\det(L) = 4$, $k = 2$; therefore $\theta \in M_1(\Gamma_0(4), \left( \frac{-1}{\cdot} \right))$. Moreover, from theorems of number theory one knows an explicit formula for the number of representations of an integer by the quadratic form $x^2+y^2$. More precisely one has:

$$\theta(\tau) = 1 + 4 \cdot \sum_{n=1}^{\infty} \left( \sum_{d \mid n} \left( \frac{-\tau}{d} \right) \right) \cdot e^{2\pi i \tau n}.$$

For further information on theta series see [Sch74] and [Og69].
2.3 Lattice functions

Let \( F : \{ \text{lattices } L \subset \mathbb{C} \} \to \mathbb{C} \) be a homogeneous function of degree \(-k\), i.e.
\[
F(\lambda L) = F(L) \cdot \lambda^{-k}
\]
for all \( \lambda \in \mathbb{C}^* \).

An example for \( k > 2 \) is: \( s_k(L) = \sum_{\tau \in \mathbb{H} \setminus \{0\}} \frac{1}{\tau^k} \).

Now define \( f(\tau) := F(Z\tau + Z) \); then \( f|_k A = f \) for all \( A = (a \ b ; c \ d) \in \text{SL}_2(\mathbb{Z}) \), for we have:
\[
(f|_k A)(\tau) = (c\tau + d)^{-k} \cdot f(\frac{a\tau + b}{c\tau + d}) = F(Z\frac{a\tau + b}{c\tau + d} + Z)
\]
\[
= F(Z(c\tau + b) + Z(c\tau + d)) = F(Z\tau + Z) = f(\tau)
\]
(note that with \((\tau, 1)\) also \((c\tau + b, a\tau + d)\) is a basis of \( \mathbb{Z}\tau + \mathbb{Z} \)).

On the other hand, if \( f|_k A = f \) for all \( A \in \text{SL}_2(\mathbb{Z}) \), then
\[
F(Z\omega_2 + Z\omega_1) := \omega_1^{-k} \cdot f(\omega_2/\omega_1)
\]
(with \( \text{Im}(\omega_2/\omega_1) > 0 \)) defines a lattice function, homogeneous of degree \(-k\). This connection can be generalized:

Lemma: Let the function
\[
F : \{(L, \omega_0) \mid L \text{ lattice, } \omega_0 \text{ primitive } \mathbb{N}-\text{division point of } \mathbb{C}/L \} \to \mathbb{C}
\]
be homogeneous of degree \(-k\), i.e.
\[
F(\lambda L, \lambda \omega_0) = \lambda^{-k} \cdot F(L, \omega_0),
\]
let \( f \) be defined by
\[
f(\tau) := F(Z\tau + Z, \frac{1}{N});
\]
then \( f|_k A = f \) for all \( A \in \Gamma_1(N) \).

Proof: Here the second argument is always regarded as a class modulo \( L \):
\[
(f|_k A)(\tau) = F(\frac{a\tau + b}{c\tau + d} + Z, \frac{1}{N}) \cdot (c\tau + d)^{-k}
\]
\[
= F(Z(a\tau + b) + Z(c\tau + d), \frac{c\tau + d}{N})
\]
\[
= F(Z\tau + Z, \frac{1}{N} \tau + \frac{d}{N}) = f(\tau).
\]
For the next to last equality observe that \( c \equiv 0 \pmod{N} \) and \( d \equiv 1 \pmod{N} \), hence \( \frac{1}{N} \tau + \frac{d}{N} \equiv \frac{1}{N} (Z\tau + Z) \).

On the other hand, if \( f \) transforms as a modular form on \( \Gamma_1(N) \) of weight \( k \), then one can define a function \( F : \{(L, \omega_0), \omega_0 \text{ as above} \} \to \mathbb{C} \) by \( F(L, \omega_0) := \omega_1^{-k} \cdot f(\omega_2/\omega_1) \).

Here \( \omega_1 = N\omega_0 \) and \( \omega_2 \) is chosen so that \( L = Z\omega_2 + Z\omega_1 \) and \( \text{Im}(\omega_2/\omega_1) > 0 \).

That one can find such an \( \omega_2 \) for a suitable choice of representative \( \omega_0 \) of \( \bar{\omega}_0 \) is left to the reader as an exercise (or cf. Lemma 7.5).

Lemma: This function \( F \) is well-defined and homogeneous of degree \(-k\).
3 The Weierstraß $\wp$-function as a Jacobi form

If one considers further the last two examples of the previous paragraph, one is led to the theory of the so-called Jacobi forms (cf. [EiZa85]). We shall not define Jacobi forms in complete generality, rather we shall consider only some special cases of interest to us. We consider the following situation:

(J) For $\tau \in \mathfrak{h}$, let $x \mapsto \Phi(\tau, x)$ be a meromorphic, periodic (hence elliptic) function with respect to the lattice $2\pi i(\mathbb{Z}\tau + \mathbb{Z})$. Further, let $k \in \mathbb{Z}$, $\Gamma \subset \text{SL}_2(\mathbb{Z})$ of finite index, and assume that:

$$
\Phi(A\tau, -\frac{a}{c\tau+d})(c\tau+d)^{-k} = \Phi(\tau, x) \quad \text{for } A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma.
$$

Such functions on $\mathfrak{h} \times \mathbb{C}$ are called Jacobi forms on $\Gamma$ of weight $k$ (and index 0), if certain additional regularity conditions are fulfilled.

Example: The Weierstraß $\wp$-function is defined as

$$
\wp(\tau, x) := \frac{1}{x^2} + \sum_{\gamma \in 2\pi i(\mathbb{Z}\tau + \mathbb{Z})} \left( \frac{1}{(x-\gamma)^2} - \frac{1}{\gamma^2} \right),
$$

and fulfills (J) with $\Gamma = \text{SL}_2(\mathbb{Z})$ and $k = 2$.

**Theorem 3.1:** Let $\Phi : \mathfrak{h} \times \mathbb{C} \to P_1(\mathbb{C})$ be a function which satisfies the assumptions (J). Let $n \in \mathbb{Z}$, $\alpha, \beta \in \mathbb{R}$ and let $g_n(\tau)$ be the $n$-th coefficient in the Taylor expansion of $\Phi(\tau, \cdot)$ at $2\pi i(\alpha \tau + \beta)$. Then we have:

$$
g_n|_{k+n}A = g_n \quad \text{for all } A \in \Gamma \text{ with } (\alpha, \beta)A \equiv (\alpha, \beta) \mod \mathbb{Z}^2.
$$

**Proof:** By the Cauchy integral formula,

$$
g_n(\tau) = \frac{1}{2\pi i} \oint \Phi(\tau, x + 2\pi i(\alpha \tau + \beta)) \frac{dx}{x^{n+1}}
$$

and therefore

$$
g_n|_{k+n}A(\tau) = g_n(A\tau)(c\tau+d)^{-(k+n)}
$$

$$
= \frac{1}{2\pi i} \oint \Phi(A\tau, (x(c\tau+d) + 2\pi i(\alpha' \tau + \beta'))/(c\tau+d)) \frac{(c\tau+d)^{-k} d(x(c\tau+d))}{(x(c\tau+d))^{n+1}}
$$

with $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ and $(\alpha', \beta') = (\alpha, \beta)A$. By substituting $x$ for $x(c\tau+d)$ and using (J), the assertion follows.

**Example:** Put $e_1(\tau) := \wp(\tau, \pi i)$. This therefore transforms as a modular form of weight two with respect to $\{ A \in \text{SL}_2(\mathbb{Z}) \mid (0, \frac{1}{2})A \equiv (0, \frac{1}{2}) \mod \mathbb{Z}^2 \}$. The latter set is nothing else than the group $\Gamma_0(2)$. 

\[\Box\]
More generally, we want to consider the Taylor coefficients of $\wp(\tau, x)$ around any expansion point. For this, we prove the following

**Theorem 3.2:** We have

$$\wp(\tau, x) = \sum_{n \in \mathbb{Z}} \frac{1}{(q^{n/2} \zeta^{1/2} - q^{-n/2} \zeta^{-1/2})^2} - \left( -\frac{1}{12} + \sum_{n \in \mathbb{Z}, n \neq 0} \frac{1}{(q^{n/2} - q^{-n/2})^2} \right). \quad (1)$$

Here we make the convention, for now and the following, that:

$$q = e^{2\pi i \tau} \quad \text{and} \quad \zeta = e^x.$$

**Proof:** As is easily checked, the first summand is normally convergent, and, for fixed $\tau$, it is periodic in $x$ with respect to $2\pi i (\mathbb{Z} \tau + \mathbb{Z})$. It has poles precisely at the lattice points, each of order two; therefore for fixed $\tau$ the function defined by the first sum is $\wp(\tau, \cdot)$ up to addition of a constant. The asserted identity now follows from the facts that $\wp(x) = \frac{1}{x^2} + O(x)$ and that the function defined by the first sum is equal for $x$ tending to 0 to

$$\frac{1}{(\zeta^{1/2} - \zeta^{-1/2})^2} + \sum_{n \neq 0} \frac{1}{(q^{n/2} - q^{-n/2})^2} + O(x)$$

$$= \frac{1}{x^2} - \frac{1}{12} + \sum_{n \neq 0} \frac{1}{(q^{n/2} - q^{-n/2})^2} + O(x).$$

With the help of the identity

$$\frac{1}{(a^{1/2} - a^{-1/2})^2} = \frac{a}{(1 - a)^2} = \sum_{k=1}^{\infty} k \cdot a^k \quad (|a| < 1)$$

we obtain immediately from (1) the

**Lemma 3.3:** For $|q| < \min\{|\zeta|, |\zeta^{-1}|\}$ we have

$$\wp(\tau, x) = \frac{1}{(\zeta^{1/2} - \zeta^{-1/2})^2} + \sum_{n=1}^{\infty} \left( \sum_{d|n} d(\zeta^d + \zeta^{-d}) \right) q^n + \frac{1}{12} \left( 1 - 24 \sum_{n=1}^{\infty} \sigma_1(n) q^n \right).$$

Here

$$\sigma_\tau(n) := \sum_{d|n} d^\tau.$$

At this point we shall introduce the Bernoulli numbers $B_i$, which are defined as follows:

$$\frac{x}{e^x - 1} = \sum_{i=0}^{\infty} \frac{B_i}{i!} x^i.$$
In particular, $B_0 = 1$, $B_1 = -\frac{1}{2}$ and $B_{2k+1} = 0$ for $k \geq 1$. Moreover, one has the following table:

<table>
<thead>
<tr>
<th>$k$</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
<th>9</th>
<th>10</th>
</tr>
</thead>
<tbody>
<tr>
<td>$B_{2k}$</td>

</tr>
</tbody>
</table>

**Bernoulli numbers**

We further have

$$\frac{\coth(x/2)}{2} = \frac{1}{\zeta - 1} + \frac{1}{2} + \frac{1}{x} + \sum_{i=1}^{\infty} \frac{B_{2i}}{(2i)!} x^{2i-1}$$

and therefore

$$\frac{1}{(\zeta^{1/2} - \zeta^{-1/2})^2} = \frac{1}{4 \sinh(x/2)^2} = \frac{d}{dx} \left( \frac{\coth(x/2)}{2} \right) = \frac{1}{x^2} - \sum_{i=1}^{\infty} \frac{B_{2i}}{2i} \frac{x^{2i-2}}{(2i-2)!}. \tag{2}$$

By means of the Fourier expansion of the $\varphi$-function we now obtain the

**Theorem 3.4:** For $k > 1$,

$$E_{2k} = 1 - \frac{4k}{B_{2k}} \cdot \sum_{n=1}^{\infty} \left( \sum_{d|n} \sigma_{2k-1}(d) \cdot q^n \right)$$

$$= 1 - \frac{4k}{B_{2k}} \cdot \sum_{n=1}^{\infty} \sigma_{2k-1}(n) \cdot q^n.$$

**Proof:** Consider the Laurent expansion of $\varphi(\tau, x)$ around $x = 0$. On the one hand, directly from the definition of the $\varphi$-function and the Taylor formula, we find the
The Weierstraß $p$-function as a Jacobi form

The $(2k - 2)$-nd coefficient to be

$$
\frac{(2k - 1)!}{(2k - 2)!} \cdot \sum_{\gamma \in 2\pi i (\mathbb{Z} + \mathbb{Z}) \atop \gamma \neq 0} \frac{1}{\gamma^{2k}} = \frac{2k - 1}{(2\pi i)^{2k}} \cdot \sum_{m,n \in \mathbb{Z} \atop (m,n) \neq 0} \frac{1}{(m\tau + n)^{2k}}
$$

$$
= \frac{2k - 1}{(2\pi i)^{2k}} \cdot \sum_{n=1}^{\infty} \frac{1}{n^{2k}} \sum_{\substack{c,d \in \mathbb{Z} \atop (c,d) \neq 0 \atop \gcd(c,d) = 1}} \frac{1}{(c\tau + d)^{2k}}
$$

$$
= \frac{2k - 1}{(2\pi i)^{2k}} \cdot \zeta(2k) \cdot 2E_{2k}(\tau),
$$

the latter directly from the definition of $E_{2k}$ (cf. §2, formula (2)) and the definition of the Riemann $\zeta$-function $\zeta(s) := \sum_{n \geq 1} n^{-s}$.

On the other hand, it follows from Lemma 3.3 and (2) that the $(2k - 2)$-nd coefficient of the $p$-function is none other than

$$
-\frac{2k - 1}{(2k)!} B_{2k} + \frac{2}{(2k - 2)!} \cdot \sum_{n=1}^{\infty} \sigma_{2k-1}(n) \cdot q^n.
$$

A comparison of the two expressions yields

$$
\frac{2k - 1}{(2\pi i)^{2k}} \cdot \zeta(2k) \cdot 2E_{2k} = -\frac{2k - 1}{(2k)!} B_{2k} + \frac{2}{(2k - 2)!} \cdot \sum_{n=1}^{\infty} \sigma_{2k-1}(n) \cdot q^n.
$$

Since $E_{2k} = 1 + O(q)$ by Theorem 2.1, the assertion follows at once, as does the following corollary.

**Corollary 3.5 (Euler):** For the Riemann $\zeta$-function, we have

$$
\zeta(2k) = -\frac{1}{2} \frac{(2\pi i)^{2k}}{(2k)!} B_{2k}.
$$

**Remark:** This also holds for $k = 1$, on the basis of other considerations.

We now define

$$
E_2(\tau) := 1 - 24 \sum_{n=1}^{\infty} \sigma_1(n) \cdot q^n
$$

and

$$
G_{2k}(\tau) := -\frac{B_{2k}}{4k} E_{2k} = -\frac{B_{2k}}{4k} + \sum_{n=1}^{\infty} \sigma_{2k-1}(n) \cdot q^n,
$$

(3)
or equivalently (in view of Theorem 3.4 and its corollary)

\[ G_{2k}(\tau) := \frac{\zeta(2k)}{(2\pi i)^{2k}} (2k-1)! \cdot E_{2k}, \]

hence for \( k \geq 2 \)

\[ G_{2k}(\tau) = \frac{(2k-1)!}{2} \cdot \sum_{\gamma \in \mathbb{Z}(2\tau+2) \setminus \{0\}} \frac{1}{\gamma^{2k}}. \]  

(4)

We thereby obtain as an alternative formulation of Lemma 3.3:

\[ \varphi(\tau, x) = \frac{1}{x^2} + 2 \sum_{k=2}^{\infty} G_{2k}(\tau) \frac{x^{2k-2}}{(2k-2)!}. \]

As a further consequence of Lemma 3.3 and as an illustration of Theorem 3.1 one has

**Theorem 3.6:** The constant terms \( e_1(\tau) := \varphi(\tau, \pi \tau), \ e_2(\tau) := \varphi(\pi \tau, \tau), \) and \( e_3(\tau) := \varphi(\pi \tau + \tau) \) of the Taylor expansion at the primitive two-division points are modular forms of weight 2 (with respect to different groups). They are permuted by the \( \frac{\mathbf{1}}{2} \)-operation of \( \text{SL}_2(\mathbb{Z}) \), \( e_1(\tau) \) being invariant under \( \Gamma_0(2) \). We have:

\[ e_1(\tau) = -\frac{1}{6} \cdot (1 + 24 \cdot \sum_{n=1}^{\infty} \sigma_1^{\text{odd}}(n) q^n) \in M_2(\Gamma_0(2)), \]

\[ e_2(\tau) = \frac{1}{12} \cdot (1 + 24 \cdot \sum_{n=1}^{\infty} \sigma_1^{\text{odd}}(n) q^{n/2}) \in M_2(\Gamma_0(2)), \]

\[ e_3(\tau) = \frac{1}{12} \cdot (1 + 24 \cdot \sum_{n=1}^{\infty} \sigma_1^{\text{odd}}(n) (-1)^n q^{n/2}) \in M_2((-1, 1/6) \Gamma_0(2)(1/6, -1/6)). \]

Here \( \sigma_1^{\text{odd}}(n) = \sum_{d|n, d \neq 1} d. \)

**Proof:** That \( e_1, e_2, \) and \( e_3 \) transform as modular forms for \( \Gamma_0(2), \Gamma_0^2(2), \) etc., follows from Theorem 3.1. That they are holomorphic on \( \mathfrak{H} \) and at the cusp \( \infty \) can be derived from their Fourier expansions, which in turn are given by Lemma 3.3. That they are permuted by \( \text{SL}_2(\mathbb{Z}) \) follows from \( \varphi(A \tau, \frac{\alpha}{c} \tau + \frac{\beta}{d}) (c \tau + d)^{-2} = \varphi(\tau, x) \), for \( A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{SL}_2(\mathbb{Z}) \), whence for \( \varphi(\alpha, \beta)(\tau) := \varphi(\tau, \alpha \tau + \beta) \) we have

\[ \varphi(\alpha, \beta)|_2(A)(\tau) := \varphi(A \tau, \alpha A \tau + \beta)(c \tau + d)^{-2} = \varphi(\tau, \alpha' \tau + \beta') \]

\[ = \varphi(\alpha', \beta') . \]
for \((\alpha', \beta') = (\alpha, \beta)A\). The regularity at all other cusps also follows from this property of being permuted.

**Remark 3.7:** In particular we have, as will be frequently useful for the study of elliptic genera:

\[
\begin{align*}
\delta &:= -\frac{3}{2} e_1 = \frac{1}{4} + 6 \cdot \sum_{n=1}^{\infty} \sigma_1^{\text{odd}}(n) q^n \\
&= \frac{1}{4} + 6 \cdot (q + q^2 + 4q^3 + q^4 + 6q^5 + 4q^6 + \cdots) \in M_2(\Gamma_0(2)), \\
\tilde{\delta} &:= -\frac{1}{8} e_1 = -\frac{3}{8} \cdot \sum_{n=1}^{\infty} \sigma_1^{\text{odd}}(n) q^n \in M_2(\Gamma_0(2)), \\
\epsilon &:= (e_1 - e_2) \\
&= \frac{1}{16} - q + 7q^2 - 28q^3 + 71q^4 - 126q^5 + 196q^6 \pm \cdots \in M_4(\Gamma_0(2)), \\
\bar{\epsilon} &:= \frac{1}{16} (e_2 - e_3)^2 \\
&= q + 8q^2 + 28q^3 + 64q^4 + 126q^5 + 224q^6 + \cdots \in M_4(\Gamma_0(2)), \\
\iota &:= (e_2 - e_3)(e_1 - e_3)(e_2 - e_3)^2 \\
&= q - 8q^2 + 12q^3 + 64q^4 - 210q^5 \pm \cdots \in S_6(\Gamma_0(2)), \\
\Delta &:= 16 \prod_{i<j} (e_i - e_j)^2 \\
&= q - 24q^2 + 252q^3 - 1472q^4 + 4830q^5 - 6048q^6 \pm \cdots \in S_{12}(SL_2(\mathbb{Z})).
\end{align*}
\]

In each case, the property of being a modular form or cusp form for \(\Gamma_0(2)\) follows from the permutation statement of Theorem 3.6.

One can immediately derive the following relations, also useful for the study of elliptic genera:

\[
\begin{align*}
e_1 + e_2 + e_3 &= 0, \\
\tilde{\delta} &= -\frac{1}{2} \delta, \quad \delta = -2\tilde{\delta}, \quad (6) \\
\bar{\epsilon} &= \frac{1}{q} (\delta^2 - \epsilon), \quad \epsilon = 4(\delta^2 - \bar{\epsilon}), \quad (7) \\
\iota &= 16\epsilon \bar{\epsilon} = 4\epsilon (\delta^2 - \bar{\epsilon}) = 64\bar{\epsilon}(\delta^2 - \bar{\epsilon}), \quad (8) \\
\Delta &= 256\epsilon^2 \bar{\epsilon} = 16\epsilon \bar{\epsilon} = 64\epsilon^2 (\delta^2 - \epsilon) = 4096\epsilon(\delta^2 - \bar{\epsilon})^2, \quad (9) \\
e_1(\tau) &= -2e_2(2\tau). \quad (10)
\end{align*}
\]

Formula (5) follows from the Fourier expansions of \(e_1, e_2\) and \(e_3\); (6) directly from the definition; (7) directly from the definition and (5); (8) and (9) directly from the definitions, resp. (7); (10) is clear.
4 Some special functions and modular forms

4.1 The valence formula

For the derivation of the explicit description of the modular forms on \( \Gamma_0(2) \) given below, we first need a formula for \( \dim \, M_k(\Gamma_0(2)) \). One obtains this by means of the valence formula, valid for arbitrary subgroups \( \Gamma \subset \text{SL}_2(\mathbb{Z}) \) of finite index.

**Theorem 4.1** (valence formula): Let \( f \in M_k(\Gamma), \ f \neq 0 \), then

\[
\sum_{s \in \Gamma \setminus P_1(\mathbb{Q})} [\text{PSL}_2(\mathbb{Z}) : \text{PSL}_2(s)] \cdot \text{ord}_s(f) + \sum_{\tau \in \text{PSL}_2(\mathbb{Z}) \setminus \Gamma} \frac{1}{|\text{PSL}_2(\mathbb{Z}) : \Gamma_\tau|} \text{ord}_{\tau}(f) = \frac{k}{12} [\text{PSL}_2(\mathbb{Z}) : \Gamma].
\]

In the first two sums, one is to add over a complete system of representatives for the orbits of \( P_1(\mathbb{Q}) \), resp. \( \mathbb{H} \), modulo \( \Gamma \). Further, \( \text{PSL}_2(\mathbb{Z}), \text{PSL}_2(\mathbb{R}), \text{PSL}_2(\mathbb{R})/\{\pm 1\} \), and \( \Gamma_\tau, \Gamma_\tau \) are the subgroups of those elements in \( \text{PSL}_2(\mathbb{Z}) \) which leave \( s \) and \( \tau \) invariant.

**Remarks:**

(i) The first sum is finite:

\[
\#(\Gamma \setminus P_1(\mathbb{Q})) \leq \#(\text{PSL}_2(\mathbb{Z}) \setminus P_1(\mathbb{Q})) \cdot [\text{PSL}_2(\mathbb{Z}) : \Gamma] = [\text{PSL}_2(\mathbb{Z}) : \Gamma] < \infty.
\]

(ii) In the second sum, almost all terms are equal to zero (compare the proof-sketch below).

(iii) The index \( [\text{PSL}_2(\mathbb{Z}) : \text{PSL}_2(s)] \) depends only on the class \( \Gamma \)'s. It is finite as is easily deduced from the fact that \( [\text{PSL}_2(\mathbb{Z}) : \Gamma] < \infty \).

(iv) We have \( |\text{PSL}_2(\mathbb{Z}) : \Gamma_\tau| < \infty \), for as one can easily prove (cf. Lemma 7.8), we have (with \( \rho = e^{2\pi i/3} \)):

If \( \Gamma_\tau \neq 1 \), then either

\[
\tau \equiv i \mod \text{SL}_2(\mathbb{Z}) \text{ or } \tau \equiv \rho \mod \text{SL}_2(\mathbb{Z}).
\]

Further, \( \text{PSL}_2(\mathbb{Z})_i = \langle \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \rangle \) (with order 2) and \( \text{PSL}_2(\mathbb{Z})_\rho = \langle \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \rangle \) (with order 3).

**Sketch of proof:** The proof of the valence formula is essentially obtained by an application of the formula of Rouché:

\[
N - P = \frac{1}{2\pi i} \cdot \int_{\partial G} d\log(f),
\]

where \( N \) is the number of zeroes and \( P \) is the number of poles of the meromorphic function \( f \) in the region \( G \). As region \( G \) one takes a fundamental domain for \( \Gamma \).
modular $\Gamma$ (the analog of the fundamental mesh of a lattice), from which one has removed neighborhoods of the cusps which are so small that they contain no zeroes and poles. This is possible since $f$ has a Fourier expansion at each cusp. Moreover, one has to take care of possible zeroes of $f$ on the boundary of $G$. To compute the integral of $d\log(f)$ along $\partial G$ one chooses a fundamental domain whose boundary consists of finitely many pairs of curves so that for each such pair there exists a transformation in $\Gamma$ identifying the curves of this pair with reversed orientation. The integral of $d\log(f)$ along each such pair is then easily computed by using the transformation law of $f$ under $\Gamma$.

For the sketched computation one may restrict to the case of a modular form on $\text{SL}_2(\mathbb{Z})$. This is due to the following observations: Let $k$ be even. Then

$$ g := \prod_{A \in \text{PT} \setminus \text{PSL}_2(\mathbb{Z})} f|_k A $$

($A$ running through a complete set of representations for the $\text{PT}$-left cosets in $\text{PSL}_2(\mathbb{Z})$) defines a modular form of weight $k \cdot [\text{PSL}_2(\mathbb{Z}) : \text{PT}]$ on the full modular group $\text{SL}_2(\mathbb{Z})$.

Hence the right hand side of the valence formula for $f$ on $\Gamma$ equals the right hand side of the valence formula for $g$, considered as a modular form on $\text{SL}_2(\mathbb{Z})$, and, as can easily be checked, the same holds true for the corresponding left hand sides. Thus the valence formula for $g$ implies the one for $f$. This argument can be modified to include the case of odd $k$. For a complete proof of the valence formula for $\Gamma = \text{SL}_2(\mathbb{Z})$ cf. [Se70], or, for the general case, cf. [Ra77], Theorem 4.14.

As a first consequence of the valence formula, we have the following

**Corollary 4.2:**

1) $M_k(\Gamma) = 0$ for all $k < 0$.

2) $\dim M_k(\Gamma) \leq 1 + \frac{k}{12} [\text{PSL}_2(\mathbb{Z}) : \text{PT}]$ for $k \geq 0$, in particular $M_0(\Gamma) = \mathbb{C}$.

**Proof:** Part 1) is a trivial consequence of the valence formula since its left hand side is always non-negative. To prove 2), note that for $\tau_1, \ldots, \tau_N \in \Delta$ pairwise inequivalent modulo $\Gamma$, each having trivial stabilizer in $\text{PT}$, the homomorphism

$$ M_k(\Gamma) \to \mathbb{C}^N $$

$$ f \mapsto (f(\tau_1), \ldots, f(\tau_N)) $$

is injective, as soon as $N$ is greater than the right side of the valence formula. Indeed, if $f \neq 0$ then the left hand side of the valence formula for $f$ is greater or equal to the number of $i$'s with $f(\tau_i) = 0$, on the other hand it is strictly less than $N$, whence $f$ cannot vanish for all the $\tau_i$.

**4.2 The ring $M_*(\Gamma)$**

If $f$ and $g$ are modular forms on a group $\Gamma$ of weight $k$ and $l$, respectively, then $f \cdot g$ is a modular form of weight $k+l$ on $\Gamma$. Hence, the subspace $M_*(\Gamma)$ of the space
of all functions on \( \mathfrak{h} \) which is spanned by all modular forms of all weights on \( \Gamma \) is a ring. Moreover, as can be easily checked, it is a graded ring, i.e.

\[
M_*(\Gamma) = \bigoplus_{k \in \mathbb{Z}} M_k(\Gamma).
\]

In this section we determine the structure of this ring in the case \( \Gamma = \Gamma_0(2) \). We write \( M_*(2) \) for \( M_*(\Gamma_0(2)) \). For \( \Gamma = \Gamma_0(2) \), the space \( \mathfrak{h}/\mathcal{P}_1(\mathbb{Q}) \) has exactly two cusps (i.e. \( \mathfrak{h}/\mathcal{P}_1(\mathbb{Q}) \) has two elements), having representatives \( \infty \) and \( 0 \) (cf. Lemma 7.11 below). Each \( \tau \in \mathfrak{h} \) with \( \mathcal{P}_1 \neq 1 \) is equivalent modulo \( \Gamma \) to \( \varepsilon := (1+i)/2 \) with \( \Gamma_\varepsilon = \langle \left( \begin{smallmatrix} 1 & 1 \\ -1 & 1 \end{smallmatrix} \right) \rangle \) (cf. Lemma 7.10 below). Finally, we have \( \text{PSL}_2(\mathbb{Z}): \text{PG} \Gamma_0(2) = 3 \) (cf. §1, formula (3)). Therefore the valence formula for \( \Gamma = \Gamma_0(2) \) can be written as:

\[
2 \text{ord}_\infty(f) + \text{ord}_0(f) + \frac{1}{2} \text{ord}_{\varepsilon}(f) + \sum_{\tau \in \mathfrak{h}/\mathcal{P}_1 \neq 0 \mod \Gamma} \text{ord}_\tau(f) = \frac{k}{4}.
\]

Using the special modular forms on \( \Gamma = \Gamma_0(2) \) introduced in Remark 3.7, we now conclude:

1) \( M_0(2) = \mathbb{C}, M_2(2) = \mathbb{C} \cdot \delta, M_4(2) = \mathbb{C} \cdot \delta^2 \oplus \mathbb{C} \cdot \varepsilon \) as a consequence of Corollary 4.2. From the Fourier expansions it follows that \( \varepsilon(\infty), \delta(\infty) \neq 0 \) and \( \text{ord}_\infty(\varepsilon) = 1/2 \) (cf. Theorem 3.6 and Remark 3.7). From this and the valence formula one deduces that \( \varepsilon(\varepsilon) = 0 \) but \( \varepsilon(\varepsilon) \neq 0 \).

2) \( M_k(2) \to S_k+\delta(2) \) is an isomorphism. The injectivity is clear. The surjectivity follows from the fact that by Remark 3.7 \( \iota \) vanishes at the cusps, and has there the minimal vanishing orders for \( \Gamma \), namely \( \text{ord}_\infty(\iota) = 1/2, \text{ord}_\infty(\iota) = 1, \) and that it has, by the valence formula, no further zeroes, whence any cusp form on \( \Gamma_0(2) \) is divisible by \( \iota \) (in the ring \( M_*(2) \)).

3) \( \delta \) and \( \varepsilon \) are algebraically independent: Since \( M_*(2) \) is a graded ring and \( \delta \) and \( \varepsilon \) are homogeneous elements (of degree 2 and 4, respectively) it suffices to show that there is no non-trivial weighted homogeneous polynomial \( P \) such that \( P(\delta, \varepsilon) = 0 \). Assume that \( P \) is such a polynomial, say of minimal degree \( 2n \). Then write \( P(\delta, \varepsilon) = a \cdot \varepsilon^n/2 + Q(\delta, \varepsilon) \cdot \delta b + \varepsilon^n \). Evaluation of \( P \) at the point \( \varepsilon \) gives \( a = 0 \); at the zero of \( \varepsilon \) (the cusp \( \Gamma_0 \)) it gives \( b = 0 \). Therefore, \( Q(\delta, \varepsilon) = 0 \), and \( Q \) has degree less than \( P \). Contradiction!

We can now prove the following structure theorem:

**Theorem 4.3:** \( M_*(2) = \mathbb{C}[\delta, \varepsilon] \).

**Proof:** By 3), \( \mathbb{C}[\delta, \varepsilon] \subset M_*(2) \) is a graded polynomial ring. The dimension of the component of degree \( k \) in \( \mathbb{C}[\delta, \varepsilon] \) is \( 1 + [k/4] \) for even \( k \) (0 otherwise). But Corollary 4.2 implies \( \dim M_k(\Gamma) \leq 1 + k/4 \). By 2), there is a practical algorithm for writing each \( f \in M_k(2) \) as a polynomial \( f = P(\delta, \varepsilon) \). Namely, \( \iota = 4 \cdot (\delta^2 - \varepsilon) \varepsilon \) and to each \( f \in M_k(\Gamma_0(2)) \) one can
find by consideration of the values at the cusps a simple polynomial $Q(δ, ε)$ so that $f - Q(δ, ε)$ is a cusp form (for the latter, note that: $\text{ord}_0(δ) = \text{ord}_∞(δ) = 0$ and $\text{ord}_0(ε) = 1/2$, $\text{ord}_∞(ε) = 0$).

**Lemma 4.4:** Let $Γ, \overline{Γ}$ be subgroups of $SL_2(\mathbb{Z})$ with $\overline{Γ} \subset T^{-1}ΓT$ for a matrix $T ∈ SL_2(\mathbb{R})$. Further, let $f(τ)$ be a modular form of weight $k$ on $Γ$. Then $f|_k T$ is a modular form on $\overline{Γ}$.

**Proof:** Let $A ∈ \overline{Γ}, A = T^{-1}AT, A ∈ Γ$. For $\overline{f} := f|_k T$ we then have:

$$f|_k \overline{A} = f|_k T^{-1}AT = f|_k TT^{-1}AT = f|_k AT$$

$$= f|_k T = \overline{f}.$$  

The regularity at the cusps follows similarly, and the holomorphicity of $\overline{f}$ is clear. \[\square\]

In particular, by this lemma the normalizer of $Γ$ in $SL_2(\mathbb{R})$ acts on $M_k(Γ)$. For $Γ = Γ_0(2)$ the following special cases are of interest to us.

**Corollary 4.5:**

1) For $f(τ) ∈ M_k(SL_2(\mathbb{Z}))$ (in particular, $f ∈ M_k(Γ_0(2))$), we have $f(2τ) ∈ M_k(Γ_0(2))$.

2) An involution $w_2$ is defined on $M_k(Γ_0(2))$ by $f|w_2 := f|_k \left( \begin{smallmatrix} 0 & -1 \sqrt{2} \\ 1 & 0 \end{smallmatrix} \right)$, the so-called Fricke-Atkin-Lehner involution.

In the main part of the book, for a given modular form $f ∈ M_k(Γ_0(2))$ one occasionally considers the special expansion

$$f^0 := f|_k \left( \begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix} \right)$$

of $f$ at the cusp $Γ_0(2)0$. Obviously we have

$$f^0(2τ) = \frac{1}{2^{k/2}} f^0|_k \left( \begin{smallmatrix} \sqrt{2} & 0 \\ 0 & 1/\sqrt{2} \end{smallmatrix} \right)(τ) = 2^{-k/2} · (f|w_2)(τ). \tag{1}$$

**Theorem 4.6:** For the special expansions $e^0_1$, $δ^0$ and $ε^0$ of $e_1$, $δ$ and $ε$ at the cusp $Γ_0(2)0$ we have:

$$e^0_1(2τ) = -\frac{1}{2} e_1(τ), \tag{2}$$

$$δ^0(2τ) = -\frac{1}{2} δ(τ) = \overline{δ}(τ), \tag{3}$$

$$e^0(2τ) = \overline{ε}(τ). \tag{4}$$
Proof: The identities for $e_1$ and $\delta$ follow from (1), since $w_2$ acts as $\pm \text{id}$ on the one-dimensional space $M_2$. The sign can be determined by taking for $\tau$ that element of $\mathfrak{h}$ satisfying $-1/\tau = 2\tau$. Now (2) and (3) follow directly. From Theorem 3.6 we know that the passage from $\tau$ to $-1/\tau$ permutes the $e_i$; more precisely, $e_1$ and $e_2$ are exchanged while $e_3$ is left fixed. Therefore we obtain:

$$e_4\left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right) = (e_2 - e_1)(e_2 - e_3) = q^{1/2} + 8q + \cdots,$$

from which (4) follows.

Theorem 4.7: The modular forms $\varepsilon$ and $\bar{\varepsilon}$ in $M_4(\Gamma_0(2))$ have the following Fourier expansions:

$$\varepsilon = \frac{1}{16} + \sum_{n \geq 1} \sum_{d|n} (-1)^d d^3 \cdot q^n, \quad (5)$$

$$\bar{\varepsilon} = \sum_{n \geq 1} \sum_{d|n, \ n/d \equiv 1(2)} d^3 \cdot q^n. \quad (6)$$

Proof: By Lemma 4.4, and since $\dim M_4(\Gamma_0(2)) = 2$, $E_4(\tau)$ and $E_4(2\tau)$ generate the space $M_4(\Gamma_0(2))$. We have

$$E_4(2\tau) = 1 + 240 \sum_{n \geq 1} \sigma_3(n) \cdot q^{2n} \quad (7)$$

$$= 1 + 240 \sum_{n \geq 1} \sum_{d|n, n/d \equiv 0(2)} d^3 \cdot q^n \quad (8)$$

$$= 1 + 30 \sum_{n \geq 1} \sum_{d|n, d \equiv 0(2)} d^3 \cdot q^n. \quad (9)$$

From $\varepsilon = \frac{1}{16} - q + \cdots$ and (9) follows $\varepsilon = -\frac{1}{240} E_4(\tau) + \frac{2}{30} E_4(2\tau)$, and therefore (5); from $\bar{\varepsilon} = 0 + q + \cdots$ and (7) follows $\bar{\varepsilon} = \frac{1}{240} E_4(\tau) - \frac{1}{240} E_4(2\tau)$, and hence (6).

4.3 $G_2$ and the Dedekind $\eta$-function

Lemma 4.8: The Eisenstein series

$$G_2 = -\frac{1}{24} + \sum_{n=1}^{\infty} \sigma_1(n) q^n$$

transforms as follows (with $G_2^*(\tau) := G_2(\tau) + \frac{1}{8\pi \Im(\tau)}$):

$$G_2\left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)(\tau) = G_2(\tau) - \frac{1}{4\pi i \tau} \quad (10)$$
resp.

\[ G_2^*|_2 A = G_2^* \]

for all \( A \in \text{SL}_2(\mathbb{Z}) \).

**Proof (after Hurwitz):** Since \( \text{SL}_2(\mathbb{Z}) \) is generated by \( \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \) and \( \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \), and the transformation behavior of \( G_2^* \) under the latter matrix is clear, the general assertion (11) follows easily from (10). For the proof of (10) we consider the function \( G(\tau) := -4\pi^2 G_2(\tau) \). From the partial fraction expansion of \( \frac{\pi^2}{\sin^2} \) follows:

\[
G(\tau) = -4\pi^2 \cdot \left( \frac{1}{24} + \sum_{n=1}^{\infty} \frac{1}{(q^{n/2} - q^{-n/2})^2} \right)
\]

where we have used \( \xi(2) = \frac{\pi^2}{6} \). Consequently,

\[
\frac{1}{\tau^2} G(-1/\tau) = \frac{\pi^2}{6\tau^2} + \frac{\pi^2}{6} + \sum_{k=1}^{\infty} \sum_{n=1}^{\infty} \left( \frac{1}{(n\tau + k)^2} + \frac{1}{(n\tau - k)^2} \right).
\]

Putting \( g_{n,k} = \frac{1}{(n\tau + k)^2} \), the difference is therefore

\[
G(\tau) - \tau^{-2} G(-1/\tau) = \sum_{n=1}^{\infty} \sum_{k=1}^{\infty} (g_{n,k} + g_{n,-k}) - \sum_{k=1}^{\infty} \sum_{n=1}^{\infty} (g_{n,k} + g_{n,-k}).
\]

For positive \( k \), define

\[ h_{n,k} := \frac{1}{(n\tau + k - 1)(n\tau + k)} = \frac{1}{n\tau + k - 1} - \frac{1}{n\tau + k}, \]

and

\[ h_{n,-k} := \frac{1}{(n\tau - k)(n\tau - k + 1)} = -\frac{1}{n\tau - k + 1} + \frac{1}{n\tau - k}; \]

then

\[ g_{n,k} - h_{n,k} = \frac{\pm 1}{(n\tau + k)^2(n\tau + k \pm 1)}. \]
Proof: The identities for $e_1$ and $\delta$ follow from (1), since $w_2$ acts as $\pm \text{id}$ on the one-dimensional space $M_2$. The sign can be determined by taking for $\tau$ that element of $\mathbb{H}$ satisfying $-1/\tau = 2\tau$. Now (2) and (3) follow directly. From Theorem 3.6 we know that the passage from $\tau$ to $-1/\tau$ permutes the $e_i$; more precisely, $e_1$ and $e_2$ are exchanged while $e_3$ is left fixed. Therefore we obtain:

$$e_4(\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}) = (e_2 - e_1)(e_2 - e_3) = q^{1/2} + 8q + \cdots,$$

from which (4) follows.

Theorem 4.7: The modular forms $\varepsilon$ and $\bar{\varepsilon}$ in $M_4(\Gamma_0(2))$ have the following Fourier expansions:

$$\varepsilon = \frac{1}{16} + \sum_{n \geq 1} \sum_{d|n} (-1)^d d^3 \cdot q^n,$$

(5)

$$\bar{\varepsilon} = \sum_{n \geq 1} \sum_{d|n} d^3 \cdot q^n.$$  

(6)

Proof: By Lemma 4.4, and since $\dim M_4(\Gamma_0(2)) = 2$, $E_4(\tau)$ and $E_4(2\tau)$ generate the space $M_4(\Gamma_0(2))$. We have

$$E_4(2\tau) = 1 + 240 \sum_{n \geq 1} \sigma_3(n) \cdot q^{2n}$$

(7)

$$= 1 + 240 \sum_{n \geq 1} \sum_{d|n, n/d \equiv 0(2)} d^3 \cdot q^n$$

(8)

$$= 1 + 30 \sum_{n \geq 1} \sum_{d|n, d \equiv 0(2)} d^3 \cdot q^n.$$  

(9)

From $\varepsilon = \frac{1}{16} - q + \cdots$ and (9) follows $\varepsilon = -\frac{1}{240} E_4(\tau) + \frac{2}{30} E_4(2\tau)$, and therefore (5); from $\bar{\varepsilon} = 0 + q + \cdots$ and (7) follows $\bar{\varepsilon} = \frac{1}{240} E_4(\tau) - \frac{1}{240} E_4(2\tau)$, and hence (6). 

4.3 $G_2$ and the Dedekind $\eta$-function

Lemma 4.8: The Eisenstein series

$$G_2 = -\frac{1}{24} + \sum_{n=1}^{\infty} \sigma_1(n) q^n$$

transforms as follows (with $G_2^*(\tau) := G_2(\tau) + \frac{1}{8\pi \text{Im}(\tau)}$):

$$G_2^*(\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}) = G_2(\tau) - \frac{1}{4\pi i \tau}.$$  

(10)
resp. \[ G_2^*|_{2A} = G_2^* \] for all \( A \in \text{SL}_2(\mathbb{Z}) \).

**Proof** (after Hurwitz): Since \( \text{SL}_2(\mathbb{Z}) \) is generated by \( \begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix} \) and \( \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \), and the transformation behavior of \( G_2^* \) under the latter matrix is clear, the general assertion (11) follows easily from (10). For the proof of (10) we consider the function \( G(\tau) := -4\pi^2 G_2(\tau) \). From the partial fraction expansion of \( \pi^2 / \sin^2 \) follows:

\[
G(\tau) = -4\pi^2 \cdot \left( -\frac{1}{24} + \sum_{n=1}^{\infty} \frac{1}{(q^{n/2} - q^{-n/2})^3} \right)
\]

\[
= \frac{\pi^2}{6} + \sum_{n=1}^{\infty} \frac{\pi^2}{\sin^2(\pi n \tau)}
\]

\[
= \frac{\pi^2}{6} + \sum_{n=1}^{\infty} \left( \frac{1}{n^2 \tau^2} + \sum_{k=1}^{\infty} \left( \frac{1}{(n \tau + k)^2} + \frac{1}{(n \tau - k)^2} \right) \right)
\]

\[
= \frac{\pi^2}{6} + \frac{\pi^2}{6 \tau^2} + \sum_{n=1}^{\infty} \sum_{k=1}^{\infty} \left( \frac{1}{(n \tau + k)^2} + \frac{1}{(n \tau - k)^2} \right),
\]

where we have used \( \xi(2) = \pi^2 / 6 \). Consequently,

\[
\frac{1}{\tau^2} \cdot G(-1/\tau) = \frac{\pi^2}{6 \tau^2} + \frac{\pi^2}{6} + \sum_{n=1}^{\infty} \sum_{k=1}^{\infty} \left( \frac{1}{(n \tau - k)^2} + \frac{1}{(n \tau + k)^2} \right).
\]

Putting \( g_{n,k} = \frac{1}{(n \tau + k)^2} \), the difference is therefore

\[
G(\tau) - \tau^{-2} G(-1/\tau) = \sum_{n=1}^{\infty} \sum_{k=1}^{\infty} (g_{n,k} + g_{n,-k}) - \sum_{k=1}^{\infty} \sum_{n=1}^{\infty} (g_{n,k} + g_{n,-k}).
\]

For positive \( k \), define

\[
h_{n,k} := \frac{1}{(n \tau + k - 1)(n \tau + k)} = \frac{1}{n \tau + k - 1} - \frac{1}{n \tau + k},
\]

and

\[
h_{n,-k} := \frac{1}{(n \tau - k)(n \tau - k + 1)} = -\frac{1}{n \tau - k + 1} + \frac{1}{n \tau - k};
\]

then

\[
g_{n,k} - h_{n,k} = \frac{\pm 1}{(n \tau + k)^2 (n \tau + k \pm 1)}.
\]
is absolutely summable. Therefore the following exchange of order of summation is permitted:

\[
\sum_{n=1}^{\infty} \sum_{k=1}^{\infty} (g_{n,k} + g_{n,-k}) - \sum_{n=1}^{\infty} \sum_{k=1}^{\infty} (h_{n,k} + h_{n,-k}) = \sum_{k=1}^{\infty} \sum_{n=1}^{\infty} (g_{n,k} + g_{n,-k}) - \sum_{k=1}^{\infty} \sum_{n=1}^{\infty} (h_{n,k} + h_{n,-k}),
\]

and the difference we are attempted to evaluate is:

\[
\sum_{n=1}^{\infty} \sum_{k=1}^{\infty} (h_{n,k} + h_{n,-k}) - \sum_{k=1}^{\infty} \sum_{n=1}^{\infty} (h_{n,k} + h_{n,-k}).
\]

Now the first sum is 0, since one verifies immediately that the inner sum vanishes for each \(n\). For the second sum we obtain, using the partial fraction expansion for the cotangent:

\[
\sum_{k=1}^{\infty} \sum_{n=1}^{\infty} (h_{n,k} + h_{n,-k}) = \sum_{k=1}^{\infty} \sum_{n=1}^{\infty} \left( \frac{1}{n + \frac{k-1}{\tau}} + \frac{1}{-n + \frac{k-1}{\tau}} - \frac{1}{n + \frac{k}{\tau}} - \frac{1}{-n + \frac{k}{\tau}} \right) = -\frac{\pi}{\tau} \cot\left(\frac{\pi}{\tau}\right) + 1 + \sum_{k=2}^{\infty} \left( \frac{\pi}{\tau} \cot\left(\frac{\pi}{\tau}\right) - \frac{1}{k-1} - \frac{\pi}{\tau} \cot\left(\frac{\pi}{\tau}\right) + \frac{1}{k} \right)
\]

\[
= \lim_{k \to \infty} \left( -\frac{\pi}{\tau} \cot\left(\frac{\pi}{\tau}\right) + \frac{1}{k} \right) = -\frac{\pi i}{\tau} \quad \text{(for } \tau \in \mathfrak{h}).
\]

**Definition:** The Dedekind \(\eta\)-function is defined as

\[
\eta(\tau) := q^{1/24} \prod_{n=1}^{\infty} (1 - q^n).
\]

**Lemma 4.9:** We have

\[
\frac{d}{d\tau} \log(\eta(\tau)) = -2\pi i G_2(\tau),
\]

\[
\eta(-1/\tau) = e^{-2\pi i/\sqrt{\tau}} \cdot \eta(\tau),
\]

\[
\eta(\tau + 1) = e^{2\pi i/24} \eta(\tau).
\]
In (13), it is understood that the root is to be taken so that the result again lies in \( \mathfrak{h} \).

Proof:

\[
\frac{d}{d\tau} \log(\eta(\tau)) = -2\pi i \left( -\frac{1}{24} + \sum_{n=1}^{\infty} \frac{nq^n}{1 - q^n} \right)
\]

\[
= -2\pi i \left( -\frac{1}{24} + \sum_{n=1}^{\infty} \sigma_1(n)q^n \right),
\]

which is precisely \(-2\pi i G_2(\tau)\). From this and Lemma 4.8 we conclude that

\[
d(\log(\eta(-1/\tau))) = -2\pi i G_2(-1/\tau) \frac{d\tau}{\tau^2}
\]

\[
= -2\pi i G_2(\tau) - 1/(4\pi i\tau) d\tau
\]

\[
= d\log(\eta(\tau)) + 1/(2\tau) d\tau.
\]

Therefore there is a constant \( k \) so that \( \eta(-1/\tau) = k \cdot \tau^{1/2} \eta(\tau) \) for all \( \tau \in \mathfrak{h} \). For \( \tau = i \) this gives at once \( k = e^{-\pi i/4} \). The equation (14) is obvious.

Corollary 4.10: For the discriminant \( \Delta(\tau) \) defined in Remark 3.7 we have

\[
\Delta(\tau) = \eta(\tau)^{24} = q \cdot \prod_{n=1}^{\infty} (1 - q^n)^{24}.
\]

Proof: \( \eta^{24} \) is, by (13) and (14), a modular form for the full modular group of weight 12, without zeroes in \( \mathfrak{h} \) and with a zero of minimal order at \( \infty \). Therefore \( \Delta(\tau)/\eta(\tau)^{24} \in M_0(\text{SL}_2(\mathbb{Z})) \) is constant by Corollary 4.2; since \( \Delta(q) = q + O(q^2) \), this constant is 1.

Corollary 4.11: The modular forms \( \varepsilon \) and \( \bar{\varepsilon} \) of Remark 3.7 satisfy:

\[
\varepsilon = \frac{1}{16} \cdot \frac{\eta(\tau)^{16}}{\eta(2\tau)^8} \quad \text{and} \quad \bar{\varepsilon} = \frac{\eta(2\tau)^{16}}{\eta(\tau)^8}.
\]

Proof: As already remarked in the proof of Corollary 4.10, we have \( \text{ord}_\infty (\Delta) = 1 \) and therefore (since \( \Delta \) is invariant under \( \text{SL}_2(\mathbb{Z}) \)) \( \text{ord}_0 (\Delta) = 1 \). For the functions \( \xi(\tau) := \eta(\tau)^8 \) and \( \bar{\xi}(\tau) := \eta(2\tau)^8 \) we therefore have:

\[
\text{ord}_\infty (\xi) = 1/3, \quad \text{ord}_\infty (\bar{\xi}) = 2/3,
\]

\[
\text{ord}_0 (\xi) = 1/3, \quad \text{ord}_0 (\bar{\xi}) = 1/6.
\]

Therefore both right sides in (15) are regular at the cusps. Because \( \eta \) has no zeroes in \( \mathfrak{h} \), the right hand side of the asserted identities define holomorphic functions on \( \mathfrak{h} \). To
check their transformation law under $\Gamma_0(2)$ note that $\Gamma_0(2)$ is generated by $T = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ and $ST^{-2}S = -\begin{pmatrix} 1 & 0 \\ 2 & 1 \end{pmatrix}$ with $S = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$. By Lemma 4.9 we have:

$$
\begin{align*}
\xi |T &= e^{2\pi i/3} \xi, \\
\tilde{\xi} |T &= e^{4\pi i/3} \tilde{\xi}, \\
\xi |ST^{-2}S &= e^{-4\pi i/3} \xi, \\
\tilde{\xi} |ST^{-2}S &= \xi |ST^{-1}S \left( \sqrt{3} 0 \\ 1/\sqrt{3} \right) = e^{-2\pi i/3} \xi |T \left( \sqrt{3} 0 \\ 1/\sqrt{3} \right) \\
&= e^{-2\pi i/3} \tilde{\xi}.
\end{align*}
$$

Therefore both expressions above are modular forms for $\Gamma_0(2)$ of weight 4, and a comparison of the first two coefficients of the Fourier expansions with those of $\xi$ and $\tilde{\xi}$ yields the assertion.

## 5 Theta functions, divisors, and elliptic functions

### 5.1 The Weierstraß $\sigma$-function

In the following sections we shall construct and investigate various explicit examples of elliptic functions (or rather theta functions or Jacobi forms). These will usually be given by infinite sums or products of simple analytic functions. We tacitly assume that the reader will verify that the products or sums converge in an appropriate way so that the functions defined by them have the required properties. As technical tool for this the following two facts are in general sufficient. Their proof can be found in any introductory book on complex analysis.

1) Let $\sum_{n \in \mathbb{N}} f_n(x)$ be a normally convergent series of meromorphic functions (i.e. for all compacta $K$ there exists an $N \in \mathbb{N}$ such that the function $f_n$ has no poles on $K$ for $n > N$ and $\sum_{n > N} \sup_{x \in K} |f_n(x)| < \infty$). Then there exists a meromorphic function $f(x)$ with $\sum_{n \in \mathbb{N}} f_n(x) = f(x)$, $\{x \mid x \text{ pole of } f\} \subseteq \bigcup_n \{x \mid x \text{ pole of } f_n\}$, and at each pole $x$ of $f$ we have $\ord_x(f) \geq \min_{n \in \mathbb{N}} \ord_x(f_n)$.

2) Let the functions $u_n(x)$ be holomorphic on $\mathbb{C}$ and let $\prod_{n \in \mathbb{N}} (1 + u_n(x))$ be normally convergent (i.e. $\sum_{n \in \mathbb{N}} u_n(x)$ is normally convergent). Then a holomorphic limit value $u(x) = \prod_{n \in \mathbb{N}} (1 + u_n(x))$ exists. For this function $u$ holds: $\{x \mid u(x) = 0\} = \bigcup_{n \in \mathbb{N}} \{x \mid 1 + u_n(x) = 0\}$, and at the zeroes $x$ of $u$ we have $\ord_x(u) = \sum_{n \in \mathbb{N}} \ord_x(1 + u_n)$. 

In order to explicitly construct, for a prescribed divisor on an elliptic curve \( \mathbb{C}/L \), an elliptic function with precisely this divisor, one needs the Weierstraß \( \sigma \)-function. In turn, one obtains the best understanding of this by considering theta functions.

**Definition:** Let \( L \subset \mathbb{C} \) be a lattice. A meromorphic function \( f \) is called a theta function for \( L \) if \( \frac{\partial^2}{\partial x^2} \log(f(x)) \) is elliptic with respect to \( L \). The theta functions defined by \( f(x) = \exp(ax^2 + bx + c) \) for \( a, b, c \in \mathbb{C} \) are called trivial theta functions.

**Remarks:**

1) The theta functions different from zero form a group with respect to multiplication.

2) A meromorphic function \( f \) is a theta function with respect to the lattice \( L \) if and only if for each \( \gamma \in L \), \( f(x + \gamma)/f(x) \) is a trivial theta function of the form \( x \mapsto \exp(bx + c) \). In particular, for a theta function \( f \) its divisor

\[
\text{div}(f) := \sum_{x + L \in \mathbb{C}/L} \text{ord}_{x+L}(f) \cdot (x + L)
\]

is therefore well-defined. By abuse of language we sometimes write \((x)\) for \((x + L)\) when dealing with divisors on the quotient \( \mathbb{C}/L \).

With the notations \( \text{Div}(E) = \{\text{divisors on } E = \mathbb{C}/L\} \), \( \Theta_L = \{\text{theta functions } \neq 0 \text{ for } L\} \) and \( \widetilde{\Theta}_L = \{\text{trivial theta functions for } L\} \) we have the following

**Theorem 5.1:** For a fixed lattice \( L \), the canonical assignment \( f \mapsto \text{div}(f) \) induces an exact sequence of groups:

\[
1 \rightarrow \widetilde{\Theta}_L \rightarrow \Theta_L \rightarrow \text{Div}(E) \rightarrow 1.
\]

**Proof:** Clearly \( f \mapsto \text{div}(f) \) is a homomorphism. Let \( f \) lie in the kernel of \( \Theta_L \rightarrow \text{Div}(E) \), i.e. \( f \) has neither zeroes nor poles, hence \( g := \log(f) \) is globally defined, so \( f = \exp(g) \). Since \( \frac{d^2}{dx^2} \) is elliptic, it follows that \( \frac{d^2}{dx^2} = 2a \), i.e. \( g = ax^2 + bx + c \) for suitable \( a, b, c \in \mathbb{C} \), hence \( f \) is a trivial theta function. We shall see in Theorem 5.2 that the divisor \((0)\) has a preimage, namely the function \( \sigma \). The surjectivity of \( \Theta_L \rightarrow \text{Div}(E) \) now follows at once, since for \( D = \sum_{i=1}^N n_i \cdot (P_i) \in \text{Div}(E) \) with \( x_i \equiv P_i \) \( \mathbb{L} \) we have

\[
\text{div}\left( \prod_{i=1}^N (x - x_i)^{n_i} \right) = D.
\]

The function \( \sigma \) used above does indeed exist. Without loss of generality, we consider lattices of the form \( 2\pi i(\mathbb{Z} + \mathbb{Z}) \), for \( \tau \in \mathbb{H} \):

**Theorem 5.2:** For each \( \tau \in \mathbb{H} \), the product

\[
\sigma(\tau, x) := x \prod_{\gamma \in 2\pi i(\mathbb{Z} + \mathbb{Z}) \setminus \gamma \neq 0} \left(1 - \frac{x}{\gamma}\right) \cdot \exp\left(\frac{x}{\gamma} + \frac{1}{2} \left(\frac{x}{\gamma}\right)^2\right)
\]
is normally convergent in \( x \in \mathbb{C} \) and defines a theta function for the lattice \( 2\pi i(\mathbb{Z} \tau + \mathbb{Z}) \) with \( \operatorname{div} (\sigma(\tau, \cdot)) = (0) \). In terms of the Eisenstein series \( G_{2k}(\tau) \) of §3, equation (3), one has

\[
\sigma(\tau, x) = \exp \left( G_2(\tau) \cdot x^2 \right) \cdot \left( \zeta^{1/2} - \zeta^{-1/2} \right) \cdot \prod_{n=1}^{\infty} \frac{(1 - q^n \zeta)(1 - q^n \zeta^{-1})}{(1 - q^n)^2} \tag{2}
\]

\[
= x \cdot \exp \left( - \sum_{k=2}^{\infty} \frac{2}{(2k)!} G_{2k}(\tau) \cdot x^{2k} \right). \tag{3}
\]

**Proof:** We have

\[
\frac{d}{dx} \log (\sigma) = \frac{1}{x} + \sum_{\gamma \in 2\pi i(\mathbb{Z} \tau + \mathbb{Z})} \frac{1}{x - \gamma} + \frac{1}{\gamma^2}
\]

and therefore \( \frac{d^2}{dx^2} \log (\sigma) = -p(\tau, x) \). Hence \( \sigma \) is a theta function. The assertion about the zeroes is also clear, since by what was proved above the product is normally convergent.

On (2): For \( |q| < \min\{|\zeta|, |\zeta^{-1}|\} \) we have

\[
\frac{d^2}{dx^2} \log \left( \text{right side of (2)} \right)
= 2G_2(\tau) + \frac{d}{dx} \left( \frac{1}{2} \coth \left( \frac{x}{2} \right) + \sum_{n=1}^{\infty} \left( \frac{-q^n \zeta}{1 - q^n \zeta} + \frac{q^n \zeta^{-1}}{1 - q^n \zeta^{-1}} \right) \right)
= 2G_2(\tau) - \frac{1}{4 \sinh \left( \frac{x}{2} \right)^2} + \frac{d}{dx} \left( \sum_{n=1}^{\infty} \sum_{k=1}^{\infty} (\zeta^{-k} - \zeta^k) \cdot q^{nk} \right)
= 2G_2(\tau) - \frac{1}{(\zeta^{1/2} - \zeta^{-1/2})^2} - \sum_{n=1}^{\infty} \sum_{k=1}^{\infty} k (\zeta^k + \zeta^{-k}) \cdot q^{nk}
= -\frac{1}{12} + 2 \sum_{n=1}^{\infty} \sigma_1(n) q^n - \frac{1}{(\zeta^{1/2} - \zeta^{-1/2})^2} - \sum_{n=1}^{\infty} \sum_{d|n} d (\zeta^d + \zeta^{-d}) q^n
= -p(\tau, x),
\]

the latter by Lemma 3.3 and the definition of \( G_2 \). Since also \( \frac{d^2}{dx^2} \log (\sigma) = -p(\tau, x) \), as proved above, we have

\[
\sigma(\tau, x) = \exp \left( b(\tau) x + c(\tau) \right) \cdot \left( \text{right side of (2)} \right)
\]

In addition, \( \sigma \) begins with \( x + O(x^2) \) and is odd. The right side of (2) likewise begins with \( x + O(x^2) \) and is odd. Hence, \( b = c = 0 \).
On (3):

\[
\log \left( \text{right side of (1)} \right) - \log (x) = \sum_{\gamma \neq 0} \left( -\sum_{n=1}^{\infty} \frac{x^n}{n \gamma^n} + \frac{x}{\gamma} + \frac{1}{2} \left( \frac{x}{\gamma} \right)^2 \right)
\]

\[
= -\sum_{\gamma \neq 0} \sum_{n=3}^{\infty} \frac{x^n}{n \gamma^n}
\]

\[
= -\sum_{k=2}^{\infty} \frac{1}{2k} x^{2k} \sum_{\gamma \in 2\pi i (2r + Z)} \frac{1}{\gamma^{2k}}
\]

\[
= -\sum_{k=2}^{\infty} \frac{1}{2k} x^{2k} \frac{2}{(2k-1)!} G_{2k}(\tau)
\]

\[
= \log \left( \text{formula (3)} \right) - \log (x),
\]

where for the next to last equality we have used the identity (4) from §3.

Therefore, (2) and (3) are equal up to multiplication by a constant, which is obviously equal to 1.

Sometimes it is better to consider the following theta function, with the same divisor (0), in place of the \( \theta \)-function; this theta function is not normalized by \( x + O(x^5) \), but instead has a more conveniently representable behavior under translation by lattice vectors.

**Corollary 5.3:** For each \( \tau \in \mathfrak{h} \),

\[
\Phi(\tau, x) := \sigma(\tau, x) \cdot \exp \left( -G_2(\tau) \cdot x^2 \right)
\]

is a theta function for the lattice \( 2\pi i (2\tau + Z) \) with \( \text{div} \left( \Phi(\tau, \cdot) \right) = (0) \) and the normalization \( \Phi(\tau, x) = x + O(x^5) \). We have thereby:

\[
\Phi(\tau, x) = \left( \zeta^{1/2} - \zeta^{-1/2} \right) \cdot \prod_{n=1}^{\infty} \frac{(1 - q^n \zeta)(1 - q^n \zeta^{-1})}{(1 - q^n)^2}
\]

\[
= x \cdot \exp \left( -\sum_{k=1}^{\infty} \frac{2}{(2k)!} G_{2k}(\tau) \cdot x^{2k} \right)
\]

and

\[
\frac{d^2}{dx^2} \log (\Phi) = -p(\tau, x) - 2G_2(\tau) = -\sum_{n \in \mathbb{Z}} \frac{1}{4 \sinh (\frac{nx + \epsilon}{2})^2}.
\]

The \( \sigma \)- and \( \Phi \)-functions exhibit interesting invariance properties:

**Theorem 5.4:** We have

\[
\sigma \left( A\tau, \frac{x}{c\tau + d} \right) \cdot (c\tau + d) = \sigma(\tau, x),
\]

\[
\Phi \left( A\tau, \frac{x}{c\tau + d} \right) \cdot (c\tau + d) = \exp \left( \frac{cs^2}{4\pi i (c\tau + d)} \right) \cdot \Phi(\tau, x).
\]
for all \( A = (a, b; c, d) \in \text{SL}_2(\mathbb{Z}) \), and

\[
\Phi(\tau, x + 2\pi i \cdot (\lambda \tau + \mu)) = q^{-\frac{1}{24}} e^{-\lambda \pi x} (-1)^{\lambda+\mu} \cdot \Phi(\tau, x),
\]

for all \( \lambda, \mu \in \mathbb{Z} \).

**Proof:** Equation (6) follows directly from the definition of the \( \sigma \)-function. (7) follows from (6) and \( G_2(A\tau)(c\tau + d)^{-2} = G_2(\tau) - \frac{c}{4\pi i(c\tau + d)} \) (by Lemma 4.8). One verifies (8) using (4), first for \( (\lambda, \mu) = (1, 0) \), resp. \( (0, \mu) \), and then by induction on \( \lambda \) (using \( 1 + 3 + \cdots + (2\lambda - 1) = \lambda^2 \)).

### 5.2 The Jacobi form \( \varphi \)

**Theorem 5.5:** Let \( L \subset \mathbb{C} \) be a lattice, \( K_L \) the field of elliptic functions with respect to \( L \), \( \text{Div}_0(E) \) the group of divisors of degree 0 on the curve \( E = \mathbb{C}/L \) and \( \text{Div}_p(E) \) the subgroup of principal divisors on \( E \). Then \( f \mapsto \text{div}(f) \) induces an exact sequence

\[
1 \to \mathbb{C}^* \to K_L^* \to \text{Div}_p(E) \to 0
\]

and we have

\[
\text{Div}_p(E) = \{ D \in \text{Div}_0(E) \mid D = \sum_{P \in \mathbb{C}/L} n_P \cdot (P), \sum_{P \in \mathbb{C}/L} n_P \cdot P \equiv 0 \mod{L} \}.
\]

**Proof:** The exactness of the sequence (9) is immediate except for the exactness at the middle place. The latter is equivalent to the fact that there is no non-constant elliptic function without poles (recall that any doubly periodic holomorphic function is bounded on a fundamental mesh, hence on \( C \), hence constant by Liouville’s theorem).

The inclusion \( "\subset" \) of the asserted identity follows from the easily proved identities

\[
\sum_{P \in \mathbb{C}/L} \text{ord}_P(f) = \oint d\log(f) = 0,
\]

\[
\sum_{P \in \mathbb{C}/L} \text{ord}_P(f) \cdot P = \oint x \cdot d\log(f) \equiv 0 \mod{L},
\]

where the integrals are taken along the boundary of a suitably chosen (not passing through zeroes or poles) fundamental mesh of \( L \). For the inclusion \( "\supset" \): If \( D = \sum_{i=1}^{N} n_i \cdot (x_i) \in \text{Div}_0(E) \) (with not necessarily distinct \( x_i \) and \( n_i \in \{\pm 1\} \) ) such that \( \sum_{i=1}^{N} n_i x_i \in L \), then one can assume \( \sum_{i=1}^{N} n_i x_i = 0 \) (otherwise, replace \( x_1 \) by \( x_1 - n_1 \sum_{i=1}^{N} n_i x_i \)). Then the product \( f(x) := \prod_{i=1}^{N} \sigma(x - x_i) \) is elliptic with divisor \( D \), since for \( \gamma \in L \) we have

\[
\prod_{i=1}^{N} \frac{\sigma(x - x_i + \gamma)^{n_i}}{\sigma(x - x_i)^{n_i}} = \prod_{i=1}^{N} \exp(b(x - x_i)n_i + cn_i)
\]

\[
= \exp \left( (bx + c) \sum_{i=1}^{N} n_i - b \sum_{i=1}^{N} n_i x_i \right) = 1
\]
where $b$ and $c$ are determined by $\sigma(x + \tau)/\sigma(x) = \exp(bx + c)$.

We shall use Theorem 5.5 in the following to give an axiomatic characterization of various elliptic functions.

**Theorem 5.6:** For $\tau \in \mathbb{H}$, let $\varphi(\tau, x)$ denote the elliptic function with respect to $x$ for the lattice $L = 2\pi i(\mathbb{Z} \cdot 2\tau + \mathbb{Z})$ with the divisor $(\pi i + (\pi i \cdot (1 + 2\tau)) - (\pi i \cdot 2\tau) - (0)$ and the normalization $\varphi(\tau, x) = \frac{1}{x} + O(1)$ for $x \to 0$ (which, according to Theorem 5.5 exists and is uniquely determined). Then we have:

$$\varphi\left(\frac{\sigma(x + b, x + c)}{e^{\tau + d}}, \frac{e^{\tau + d}}{e^{\tau + d}}\right) \cdot (e^{\tau + d})^{-1} = \varphi(\tau, x)$$  \hspace{1cm} (10)

for all $A = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \Gamma_0(2)$.

$$\varphi(\tau, x)^2 = \varphi(\tau, x) - e_1(\tau), \hspace{1cm} (11)$$

$$\varphi(\tau, x) = \frac{1}{2} \zeta^{1/2} + \zeta^{-1/2} \cdot \prod_{n=1}^{\infty} \left(1 + q^n \zeta \right) \left(1 + q^n \zeta^{-1} \right) \left(1 - q^n \zeta \right) \left(1 - q^n \zeta^{-1} \right), \hspace{1cm} (12)$$

$$\varphi(\tau, x) = \lim_{N \to \infty} \left( \sum_{n=-N}^{N} \frac{(-1)^n}{2} \coth\left(\frac{2\pi i n \varphi + x}{2}\right) \right), \hspace{1cm} (13)$$

$$\varphi(\tau, x) = \frac{\Phi(\tau, x - \pi i)}{\Phi(\tau, x) \Phi(\tau, -\pi i)} = \frac{\sigma(\tau, x - \pi i)}{\sigma(\tau, x) \sigma(\tau, -\pi i)} \exp(2\pi i x \cdot G_2(\tau)). \hspace{1cm} (14)$$

**Proof:**

On (10): Choose a fixed $\tau$, and define

$$\psi(\tau, x) := \varphi\left(\frac{\sigma(x + b, x + c)}{e^{\tau + d}}, \frac{e^{\tau + d}}{e^{\tau + d}}\right) \cdot (e^{\tau + d})^{-1} = \frac{1}{x} + O(1).$$

For $\lambda, \mu \in \mathbb{Z}$ we have

$$\psi(\tau, x + 2\pi i(2\lambda \tau + \mu)) = \varphi\left(A \tau, \frac{\sigma(x + 2\pi i(2\lambda \tau + \mu))}{e^{\tau + d}}\right) \cdot (e^{\tau + d})^{-1}$$

$$= \varphi\left(A \tau, \frac{\sigma(x + 2\pi i(2\lambda \tau + \mu))}{e^{\tau + d}} + 2\pi i \lambda \cdot 2A \tau + \mu \right) \cdot (e^{\tau + d})^{-1}$$

$$= \varphi\left(A \tau, \frac{\sigma(x + 2\pi i(2\lambda \tau + \mu))}{e^{\tau + d}} \right) \cdot (e^{\tau + d})^{-1}$$

$$= \psi(\tau, x),$$

where $(\lambda', \mu')(\frac{a}{2}, \frac{b}{d}) = (\lambda, \mu)$. Furthermore, $\psi$ has the same zeroes and poles as $\varphi$, as one easily sees. Since $\varphi$ is uniquely determined by these properties, we therefore have

$$\varphi(\tau, x) = \psi(\tau, x) = \varphi\left(A \tau, \frac{\sigma(x + 2\pi i(2\lambda \tau + \mu))}{e^{\tau + d}}\right) \cdot (e^{\tau + d})^{-1}.$$
On (11): $\varphi(\tau, x + 2\pi i \tau) = -\varphi(\tau, x)$, since $\varphi(\tau, x + 2\pi i \tau) + \varphi(\tau, x)$ is elliptic with respect to $L = 2\pi i (Z \tau + Z)$ and has at most one pole (of order one) on $\hat{L}$, and is therefore constant. The value of the constant is 0, as one sees by taking $x = \pi i$. Hence $\varphi(\tau, x)^2$ is elliptic with respect to $L$ and has the same poles of order two as $\varphi(\tau, x)$. Thus we have $\varphi^2(\tau, x) = \varphi(\tau, x) + \text{const}$. Setting $x = \pi i$ gives const. $= -\varphi(\tau, \pi i) = -e_1(\tau)$.

On (12): Call the right side $p(x)$. The function $p$ is meromorphic and the various factors yield for the divisor: The denominator of $\coth(x)$ yields poles at $2\pi i (0 + Z)$, and the numerator yields zeroes at $2\pi i (0 + Z) + \pi i$. The product gives zeroes at $2\pi i (N\tau + Z) + \pi i$, resp. $2\pi i (-N\tau + Z) + \pi i$, and poles at $2\pi i (N\tau + Z)$, resp. $(-N\tau + Z)$. The divisors of $\varphi$ and $p$ therefore coincide. The invariance under $x \mapsto x + 2\pi i \tau$ (hence $\zeta \mapsto \zeta^q$) as follows:

$$p(x + 2\pi i \tau) = \frac{1}{2} \frac{q \zeta + 1}{q \zeta - 1} \frac{1}{\prod_{n=1}^{\infty} \frac{(1 + q^{n+1} \zeta)(1 + q^{n-1} \zeta^{-1})(1 - q^n)^2}{(1 - q^{n+1} \zeta)(1 - q^{n-1} \zeta^{-1})(1 + q^n)^2}} = -p(x).$$

The normalization of $p(x)$ is likewise $\frac{1}{x} + O(1)$. Hence $p(x)$ has precisely those properties which characterize $\varphi$ uniquely, i.e. $p = \varphi$.

On (13): Let $s(x)$ denote the function defined by the sum. Obviously $s(x + 2\pi i) = s(x)$, and one can easily show that also $s(x + 2\pi i \tau) = -s(x)$. The poles of $s$ have order 1 and lie at $2\pi i (Z \tau + Z)$. Moreover, $s(x) = \frac{1}{x} + O(1)$. Hence $\varphi = s + \text{const}$. But $s$ is odd, as is $\varphi$ obviously $(-\varphi(\tau, -x)$ satisfies the same conditions as $\varphi(\tau, x)$), hence the constant must be 0.

On (14): This follows again by verification of the properties characterizing $\varphi$ for the right side of (14), by means of the various properties of $\Phi$ given in the previous section.

Note that (12) can also be deduced from (14) and (4). Similarly, one could derive (10) from (14) and the transformation law of $\Phi$ derived in the previous section.

Exercise (expansion of $\varphi$ at the cusp 0):

$$\varphi^0(\tau, x) := \varphi \left( \frac{-1}{\tau}, \frac{x}{\tau} \right) \cdot \tau^{-1}$$

is elliptic with respect to the lattice $\tilde{L} = 2\pi i (Z \tau + Z \cdot 2)$ and has the expansion $\frac{1}{x} + O(1)$ for $x \to 0$. The poles are at $\tilde{L}$ and $2\pi i + \tilde{L}$, and we have

$$\varphi^0(\tau, x) = \frac{1}{\zeta^{1/2} - \zeta^{-1/2}} \cdot \prod_{n=1}^{\infty} \left( \frac{1 - q^{n/2}}{1 - q^{n/2} \zeta} \right)^2 \left( \frac{1 - q^{-n/2}}{1 - q^{-n/2} \zeta^{-1}} \right)^2 (1) \quad (15)$$

$$= \frac{1}{2} \sum_{n \in \mathbb{Z}} \frac{1}{\sinh \left( \frac{\pi i 2n \tau}{x} \right)}$$

(16)
I.6 Elliptic genera of level \( N \)

\[
\Phi(r, x - \pi i r) = \Phi(r, x) e^{-x/2}.
\]  

(18)

(for (16) verify that the right side \( s \) has the same poles and residues as \( \varphi^0 \), whence \( \varphi^0 = s + \text{const.} \), and use that \( \varphi^0 \) and \( s \) are odd functions).

6 Elliptic genera of level \( N \)

6.1 Tools: The \( \Phi \)-function

One obtains explicit formulas in the theory of elliptic genera of level \( N \) by application of the definitions and theorems of §5, in the same way this was done there in Theorem 5.6 for \( N = 2 \). From consideration of formula (3) in §5

\[
\sigma(r, x) = x \cdot \exp \left( - \sum_{k=1}^{\infty} \frac{2}{(2k)!} G_{2k}(r) \cdot x^{2k} \right)
\]

we are led at once to the question: How do the modular forms \( G_k \) enter into these formulas? The answer is obtained from Theorem 3.1, which we recall here in a reformulation suitable to our aims.

**Theorem 6.1** For each \( \tau \in \mathcal{H} \), let \( \Psi(r, x) \) be a doubly periodic function in \( x \) with period lattice \( L = 2\pi i(\mathbb{Z} \tau + \mathbb{Z}) \). Suppose that for a suitable number \( k \in \mathbb{Z} \), \( r \in \Gamma \subset \text{SL}_2(\mathbb{Z}) \), and group homomorphism \( \varepsilon : \Gamma \to \mathbb{C}^* \) we have

\[
\Psi(A \tau, \frac{e}{cr+d})(ct+d)^{-k} = \varepsilon(A) \cdot \Psi(r, x)
\]

for all \( A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma \) (briefly: \( \Psi \) is invariant under \( \Gamma \) of weight \( k \) with Nebentyp \( \varepsilon \)). Let \( \omega = 2\pi i(\alpha \tau + \beta) \) be an \( N \)-division point of \( L \) and \( a_n(\tau) \) the \( n \)-th coefficient of the Laurent expansion at the point \( \omega \). Then we have:

\[
a_n(A \tau)(cr+d)^{-(n+k)} = \varepsilon(A)a_n(\tau)
\]

for all \( A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma' \) with \( \Gamma' = \{ A \mid (\alpha, \beta)A \equiv (\alpha, \beta) (N) \} \); in particular, for \( \omega = 2\pi i/N \) we have \( \Gamma' = \Gamma_1(N) \cap \Gamma \).

If \( A \in \text{SL}_2(\mathbb{Z}) \), then \( \sigma(A \tau, \frac{e}{cr+d})(ct+d) \) is again a theta function for the lattice \( 2\pi i(\mathbb{Z} \tau + \mathbb{Z}) \) with divisor \( (0 + 2\pi i(\mathbb{Z} \tau + \mathbb{Z})) \), hence equal to a trivial theta function times \( \sigma(\tau, x) \). Indeed, as we have seen in formula (6) from §5, \( \sigma(\tau, x) \) is invariant
under \( SL_2(\mathbb{Z}) \). Therefore \( \sigma'/\sigma \) is also invariant under \( SL_2(\mathbb{Z}) \) (of weight 1), hence the \( k \)-th Taylor coefficient of \( \frac{\partial}{\partial x} \log(\sigma) \) is invariant under \( SL_2(\mathbb{Z}) \) (of weight \( k+1 \)), and in fact it is a multiple of \( G_{k+1} \) for odd \( k \) and 0 for even \( k \).

In view of Theorem 6.1, a formula analogous to formula (5) from §5, giving an expansion of \( \Phi \) at a general \( N \)-division point, is of interest:

**Theorem 6.2:** Let \( L = 2\pi i(2\tau + \mathbb{Z}) \) and let \( \omega = 2\pi i(\alpha \tau + \beta) \) with \(-1 < \alpha, \beta < 1\). Then

\[
\Phi(\tau, x) = \exp\left(-2 \sum_{k=1}^{\infty} \frac{(x - \omega)^k}{k!} G_k^\omega(\tau)\right) \cdot \begin{cases} x, & \text{if } \omega = 0, \\ \Phi(\tau, \omega), & \text{otherwise.} \end{cases} \tag{1}
\]

Here

\[
G_k^\omega(\tau) = -\frac{c_k^\omega}{2k} + \sum_{n=1}^{\infty} \left( \sum_{d|n} e^{d\omega} + (-1)^k e^{-d\omega} \right) \cdot \frac{d^{k-1}}{2} \cdot q^n, \tag{2}
\]

where the \( c_k^\omega \) are defined by:

\[
\frac{1}{2} \coth\left(\frac{x}{2}\right) = \sum_{k=0}^{\infty} \frac{c_k^\omega}{k!} (x - \omega)^{k-1}.
\]

**Proof:** From (4) of Corollary 5.3 we obtain for \( |q| < |\zeta|, |\zeta|^{-1} \), i.e. for \( |\text{Im}(x)| < 2\pi \text{Im}(\tau) \),

\[
\frac{\partial}{\partial x} \log(\Phi(\tau, x)) = \frac{1}{2} \coth\left(\frac{x}{2}\right) - \sum_{n=1}^{\infty} \sum_{d|n} (e^{d\omega} - e^{-d\omega}) q^n.
\]

Writing

\[
e^{d\omega} - e^{-d\omega} = \sum_{k=0}^{\infty} \left( e^{d\omega} + (-1)^{k+1} e^{-d\omega} \right) d^k \frac{(x - \omega)^k}{k!},
\]

we find

\[
\frac{\partial}{\partial x} \log(\Phi(\tau, x)) = \frac{1}{2} \coth\left(\frac{x}{2}\right) - 2 \sum_{k=0}^{\infty} G_{k+1}^\omega(\tau) \frac{(x - \omega)^k}{k!}
\]

for \( x \) near \( \omega \) (note that by assumption \( |\text{Im}(\omega)| < 2\pi \text{Im}(\tau) \), i.e. \( \omega \) is in the domain valid for the cited expansion of \( \frac{\partial}{\partial x} \log(\Phi(\tau, x)) \)). Here \( G_k^\omega = G_{k+1}^\omega - \text{const.} \) From the latter equation the claimed formula can now easily be deduced. \( \square \)

**Remarks:**

1) If \( \omega \in \frac{1}{N} L \) then it can easily be verified that the constant term of \( G_k^\omega(\tau) \) is given by

\[
-\frac{c_k^\omega}{2k} = \sum_{\nu=0}^{N-1} \frac{B_k(\nu)}{2k} e^{\nu \nu} - \delta_{k,1} \cdot \frac{1}{4}
\]
(δ_k,1 = 0 or 1 accordingly as k ≠ 1 or k = 1). Here the B_k(x) denote the Bernoulli polynomials, i.e.

\[ \frac{te^t}{e^t - 1} = \sum_{k=0}^{\infty} \frac{B_k(x)}{k!} t^k. \]

2) If \( \omega \in \frac{1}{N} L, \; \omega = 2\pi i \frac{\alpha + \beta}{N}, \) then, by Theorem 6.1 applied to \( \frac{\partial}{\partial x} \log (\Phi(\tau, x)) \), the function \( G_k^{(\omega)}(\tau) \) transforms like an element of \( M_k(\Gamma) \), where \( \Gamma = A^{-1} \Gamma(1)(N) A \) with \( A \) denoting any matrix with lower row equal to \((\alpha, \beta)\). In fact, it is easily checked that \( G_k^{(\omega)} \in M_k(\Gamma) \); The regularity at the cusps follows from the fact that \( G_k^{(\omega)} |_k M = G_k^{(\omega')} \) with a suitable \( \omega' \) for any \( M \in SL_2(Z) \), as is easily deduced from the transformation laws of \( \Phi(\tau, x) \) as stated in (7), (8) of Theorem 5.4.

Example: Applying the preceding remark 2) to \( \omega = -2\pi i/3 \) one finds

\[ G_1^{(-2\pi i/3)}(\tau) = -\frac{\sqrt{3}}{2} \cdot \left( \frac{1}{6} + \sum_{n=1}^{\infty} \sum_{d | n} \left( \frac{d}{3} \right) \cdot q^n \right) \in M_1(\Gamma(3)); \]

\[ G_3^{(-2\pi i/3)}(\tau) = -\frac{\sqrt{3}}{2} \cdot \left( -\frac{1}{486} + \sum_{n=1}^{\infty} \sum_{d | n} d^2 \left( \frac{d}{3} \right) \cdot q^n \right) \in M_3(\Gamma(3)). \]

Here \( \left( \frac{d}{3} \right) \) is the Legendre symbol (i.e. \( \left( \frac{d}{3} \right) = -1, 0, 1 \) for \( d \equiv -1, 0, 1 \)).

Remark: One can show that

\[ M_\omega(\Gamma(3)) = \mathbb{C}[G_1^{(-2\pi i/3)}, G_3^{(-2\pi i/3)}]. \]

6.2 The function \( f \) for elliptic genera of level \( N \)

We now want to use the methods presented above to study the function \( f(x) \) introduced by Hirzebruch in Chapter 7.

Theorem 6.3: Let \( N \in \mathbb{N} \) and \( \alpha, \beta \in \mathbb{Z} \), not both divisible by \( N \). Then there is a unique function \( f_{\alpha, \beta}(\tau, x) \) with the following properties:

1) \( x \mapsto f_{\alpha, \beta}(\tau, x) \) is a theta function on the lattice \( 2\pi i(\mathbb{Z}\tau + \mathbb{Z}) \).

2) The divisor of \( f_{\alpha, \beta}(\tau, x) \) is \((0) - (2\pi i \frac{\alpha + \beta}{N})\).

3) \( f_{\alpha, \beta}(\tau, x) = x + O(x^2) \) for \( x \to 0 \) and for all \( \lambda, \mu \in \mathbb{Z} \) there exists an \( N \)-th root of unity \( \nu \) so that

\[ f_{\alpha, \beta}(\tau, x + 2\pi i(\lambda \tau + \mu)) = \nu \cdot f_{\alpha, \beta}(\tau, x), \]

i.e. \( x \mapsto f_{\alpha, \beta}^N(\tau, x) \) is doubly periodic with respect to \( 2\pi i(\mathbb{Z}\tau + \mathbb{Z}) \).
Remark: Obviously one has $f_{\alpha, \beta}(\tau, x) = f_{\alpha', \beta'}(\tau, x)$ if $(\alpha, \beta) \equiv (\alpha', \beta') (N)$.

Proof: By Theorem 5.1, $f_{\alpha, \beta}$ satisfying 1) and 2) certainly exists and is unique up to multiplication with $e^{ax + bx + c}$. Now $f_{\alpha, \beta}^N$ is a theta function with divisor $N \cdot ((0) - (2\pi i \frac{\alpha \tau + \beta}{N} \)), and $N \cdot (0 - 2\pi i \frac{\alpha' \tau + \beta'}{N} \)) \in 2\pi i(\mathbb{Z} \tau + \mathbb{Z})$. By combining Theorem 5.1 and Theorem 5.5, we find that $f_{\alpha, \beta}^N$ is, up to multiplication by a trivial theta function $\theta$, a doubly periodic function on $2\pi i(\mathbb{Z} \tau + \mathbb{Z})$. Multiplying $f_{\alpha, \beta}$ by const. $\frac{1}{\sqrt{\theta}}$, if necessary, one can therefore assume that $f_{\alpha, \beta}^N$ is elliptic with respect to $2\pi i(\mathbb{Z} \tau + \mathbb{Z})$ and satisfies $f_{\alpha, \beta}(\tau, x) = x + O(x^2)$ ($x \to 0$). Note that this $f_{\alpha, \beta}^N$ is uniquely determined (as is also implied by Theorem 5.5). This proves the theorem.

Theorem 6.4: Let $f_{\alpha, \beta}(\tau, x)$ be as in the preceding theorem and let $f(\tau, x) = f_{0,1}(\tau, x)$. Then one has:

(i) $f_{\alpha, \beta}(\tau, x) = \frac{\Phi(\tau, x) \Phi(\tau, -\omega)}{\Phi(\tau, x - \omega)} \cdot e^{\alpha x / N} \quad (\omega = 2\pi i \frac{\alpha \tau + \beta}{N})$, \hspace{1cm} (3) \\

(ii) $f_{\alpha, \beta}(\tau, x) = 2e^{\frac{x}{2}} \frac{\sinh \left( \frac{x}{2} \right) \sinh \left( \frac{\omega}{2} \right)}{\sinh \left( \frac{x - \omega}{2} \right)} \prod_{n=1}^{\infty} \frac{(1 - q^n e^{x}) (1 - q^n e^{-x}) (1 - q^n e^{\omega}) (1 - q^n e^{-\omega})}{(1 - q^n e^{x-\omega}) (1 - q^n e^{x+\omega}) (1 - q^n)^2}$, \hspace{1cm} (4) \\

where

\begin{equation}
\begin{aligned}
f_k(\tau) &= \frac{c_k(-2\pi i/N)}{2k} - \sum_{n=1}^{\infty} \left( \sum_{d|n} d^{k-1} \cdot \left\{ \cos \left( \frac{-2\pi id}{N} \right) \sin \left( \frac{2\pi id}{N} \right) \right\} \text{ for } k \equiv 0 \text{ (2)} \right) \cdot q^n \\
&\quad \in M_k(\Gamma_1(N)), \\
\end{aligned}
\end{equation}

with $c_k(\omega)$ as in Theorem 6.2.

(ii) $f_{\alpha, \beta}(A\tau, \frac{x}{\tau + d}) (c\tau + d) = f_{\alpha, \beta}(\tau, x)$ \hspace{1cm} (8)

for all $A \in \text{SL}_2(\mathbb{Z})$, in particular for $f(\tau, x)$ one has

\begin{equation}
f(A\tau, \frac{x}{\tau + d}) (c\tau + d) = f(\tau, x) \quad \text{for all } A \in \Gamma_1(N).
\end{equation}

(iii) $f_{\alpha, \beta}(\tau, x + 2\pi i (\lambda \tau + \mu)) = \exp \left( 2\pi i (\alpha \mu - \beta \lambda) / N \right) \cdot f_{\alpha, \beta}(\tau, x)$, \hspace{1cm} (10)

for all $\lambda, \mu \in \mathbb{Z}$.
Proof: The right side of (3) satisfies the conditions 1), 2), and the normalization condition in 3) of Theorem 6.3: One verifies (10) for the right side, using formula (8) from §5. Hence the right side of (3) also satisfies 3) in Theorem 6.3, and so is equal to \( f_{\alpha, \beta} \). This also implies (10). The product representation of \( \Phi \) then yields (5). Further, (6) is a consequence of (3) and Theorem 6.2 (formulas (1) and (2)). Formula (7) follows from (9) by logarithmic differentiation of \( f \) and Theorem 6.1. Formula (9) follows from (8), and (8) follows from the fact that \( f_{\alpha, \beta}(A\tau, \frac{x}{\omega + d}) \cdot (c \tau + d) \) satisfies the conditions 1), 2) and 3) of Theorem 6.3, with \((\alpha, \beta)A\) in place of \((\alpha, \beta)\): e.g., 3) results, with \((\lambda', \mu')A = (\lambda, \mu)\), as follows:

\[
f_{\alpha, \beta}(A\tau, \frac{x + 2\pi i(\tau + \mu)}{c \tau + d}) = f_{\alpha, \beta}(A\tau, \frac{x + 2\pi i(\lambda' \tau + \lambda' \mu)}{c \tau + d}) \\
= f_{\alpha, \beta}(A\tau, \frac{x}{c \tau + d} + 2\pi i(\lambda' \tau + \mu')) \\
= \exp\left(\frac{2\pi i}{\tau}(\lambda' \mu' - \beta \lambda')\right) \cdot f_{\alpha, \beta}(A\tau, \frac{x}{c \tau + d}).
\]

7 \( N \)-division points and \( \Gamma_1(N) \backslash \mathfrak{h} \)

7.1 Almost-Chebyshev polynomials and elliptic functions

In the preceding paragraph we have seen that to a given elliptic curve \( E = \mathbb{C}/L \) with a fixed non-zero \( N \)-division point \( Q = \omega + L \) (i.e. \( N \cdot \omega \in L \) and \( \omega \notin L \)) there exists a theta function \( f(x) \) for which:

- \( \text{div} (f) = (0) - (Q) \),
- \( f^N(x) \) is doubly periodic with respect to \( L \),
- \( f(x) = x + O(x^2) \) for \( x \to 0 \),

and that \( f \) is uniquely determined by these properties.

From the definition it follows immediately that

\[
\text{div} (f(x) \cdot f(-x + \omega)) = 0
\]

and so

\[
f(x) \cdot f(-x + \omega) \equiv c^{-2} \neq 0
\]

for a suitable constant \( c \). Thus \((cf)^N + (cf)^{-N}\) induces a function on \( X = (\mathbb{C}/L)/(\tau) \), where \( \tau : x \mapsto \omega - x \). The same holds true for \( f'/f \) since its pole divisor \(-0) - (\omega)\) is invariant under \( \tau \), and its residues are +1 and -1, respectively, whence \( f'/f = \)
154 I Modular forms

$f'/f \circ \tau + \text{const.},$ and const. = 0, as follows by setting $x = w/2$ in this equation. Moreover, this also shows that $f'/f$, as function on $X$, has exactly one pole which is of order 1, i.e. $f'/f$ defines a biholomorphic map between $X$ and $P_1(\mathbb{C})$ and thus generates the function field of $X$. Thus there exists a rational function $P$ so that

$$P(f'/f) = f^{-N} + c^{2N} f^N. \quad (1)$$

Clearly, $P$ is uniquely determined by this identity. Since $f^{-N} + c^{2N} f^N$, as a function on $X$, has a pole only at the same point as $f'/f$, it follows that $P$ is even a polynomial. As Hirzebruch observed, $(1)$ implies that $P$ is a normalized almost-Chebyshev polynomial of degree $N$, i.e.

- $P(x) = x^N + \cdots,$
- $P'(x) = N \cdot x \cdot (x - \xi_1) \cdots (x - \xi_{N-2}),$
- $P(\xi_i) = \pm P(\xi_j)$ for all $i$ and $j$.

Its values at the critical points $\xi_i$ are $\pm 2 c^N$.

**Theorem 7.1:** Let $\mathcal{P}_N$ be the set of normalized almost-Chebyshev polynomials of degree $N$. For $N \geq 3$ the correspondence $(\mathbb{C}/L, Q) \mapsto P$ induces an injection

$\{(\mathbb{C}/L, Q) \mid N \cdot Q = 0, Q \neq 0\}/\text{isom} \mapsto \mathcal{P}_N / \sim. \quad (2)$

**Remark:** Here, two pairs $(\mathbb{C}/L, Q)$ and $(\mathbb{C}/\overline{L}, \overline{Q})$ of elliptic curves with distinguished $N$-division points are defined to be isomorphic if and only if there is a biholomorphic mapping $I : \mathbb{C}/L \to \mathbb{C}/\overline{L}$ which carries $O$ to $O$ and $Q$ to $\overline{Q}$. The equivalence relation on the set of almost Chebyshev polynomials is defined by

$$F(x) \sim G(x) \iff F(x) = \lambda^{-N} G(\lambda x) \text{ for some } \lambda \in \mathbb{C}^*.$$  

For the proof of Theorem 7.1 we need the following

**Proposition 7.2:** Let $I : \mathbb{C}/L \to \mathbb{C}/\overline{L}$ be holomorphic with $I(0) = 0$. Then there exists a constant $\lambda \in \mathbb{C}$ so that the following diagram commutes:

$$\begin{array}{ccc}
\mathbb{C} & \overset{\lambda}{\rightarrow} & \mathbb{C} \\
\downarrow \pi & & \downarrow \overline{\pi} \\
\mathbb{C}/L & \overset{I}{\rightarrow} & \mathbb{C}/\overline{L}. \\
\end{array}$$

**Proof:** Since $(\mathbb{C}, \overline{\pi})$ is the universal covering of $\mathbb{C}/L$, we deduce from general theorems of topology the existence of a holomorphic mapping $\widehat{I}$ so that the following diagram is commutative:

$$\begin{array}{ccc}
\mathbb{C} & \overset{\widehat{I}}{\cong} & \mathbb{C} \\
\downarrow \pi & & \downarrow \overline{\pi} \\
\mathbb{C}/L & \overset{I}{\rightarrow} & \mathbb{C}/\overline{L}. \\
\end{array}$$
Now let $\gamma \in L$. Then $x \mapsto \tilde{f}(x + \gamma) - \tilde{f}(x)$ only takes values in $\tilde{L}$ and is therefore constant, i.e. $\frac{d}{dx} \tilde{f}(x + \gamma) = \frac{d}{dx} \tilde{f}(x)$ for all $\gamma \in L$. Hence $\frac{d}{dx} \tilde{f}$ is holomorphic and elliptic with respect to $L$, thus is constant. Hence $\tilde{f}(x) = \lambda x + \mu$ for suitable $\lambda, \mu \in \mathbb{C}$, where we have $\mu = \tilde{f}(0) \in \tilde{L}$, and can therefore without restriction assume that $\mu = 0$.

Conversely, multiplication with a $\lambda \in \mathbb{C}$ for which $\lambda L \subset \tilde{L}$ obviously induces a holomorphic mapping $\mathbb{C}/L \to \mathbb{C}/\tilde{L}$. Therefore one immediately obtains from the proposition the

**Corollary 7.3:** Two pairs $(\mathbb{C}/L, Q)$ and $(\mathbb{C}/\tilde{L}, \tilde{Q})$ are isomorphic if and only if there exists a $\lambda \in \mathbb{C}$ with $\lambda L = \tilde{L}$ and $\lambda Q = \tilde{Q}$.

**Proof of the theorem:** We show first that a mapping (2) is indeed induced. Assume that one starts with two isomorphic pairs $(\mathbb{C}/L, Q)$ and $(\mathbb{C}/\tilde{L}, \tilde{Q})$ with $\lambda L = \tilde{L}$ and $\lambda Q = \tilde{Q}$, and has obtained the equations $P(f'/f) = f^{-N} + \epsilon^{2N} \cdot f^N$ and $\tilde{P}(\tilde{f}'/\tilde{f}) = \tilde{f}^{-N} + \epsilon^{2N} \cdot \tilde{f}^N$. Because of the uniqueness of $\tilde{f}$, we first obtain $\tilde{f} = \lambda \cdot f(x/\lambda)$ and then

$$\tilde{c}^{-2} = f(x) \cdot \tilde{f}(-x + \omega) = \lambda^2 f(x/\lambda) \cdot f(-x/\lambda + \omega) = \lambda^2 c^{-2}.$$  

Therefore

$$\tilde{P} \left( \lambda^{-1} \frac{f'(x/\lambda)}{f(x/\lambda)} \right) = \lambda^{-N} P \left( \frac{\tilde{f}'(x)}{\tilde{f}(x)} \right) = \lambda^{-N} \frac{1}{\lambda^N f(x/\lambda)^N} + \lambda^{-2N} \epsilon^{2N} \lambda^N f(x/\lambda)^N$$

whence $P(x) = \lambda^N \tilde{P}(\lambda^{-1} x)$.

We now show the injectivity of the mapping (2). So let $P(x)$ be given: then $\epsilon^{2N}$ is uniquely determined, since the critical values of $P$ at points unequal to zero are $\pm 2\epsilon^{2N}$. (Note that this argument does not hold true for $N = 2$.) Thus $P$ uniquely determines the differential equation $P(f'/f) = f^{-N} + \epsilon^{2N} f^N$, which in turn uniquely determines $f$. For the latter simply solve for the Laurent expansion of $f'/f$ around 0. Finally, $f$ uniquely determines $L$ and $Q$, its zeroes and poles. This completes the proof of the theorem.

**Proposition 7.4:** The correspondence $\tau \mapsto (\mathbb{C}/2\pi i(\mathbb{Z} + \mathbb{Z}), 2\pi i/N)$ induces a bijection

$$\Gamma_1(N) \backslash \mathbb{H} \to \{ (\mathbb{C}/L, Q) \mid Q \text{ is a primitive } N\text{-division point} \}/\text{isom}. \quad (3)$$
Remark:

1) Recall that an \(N\) \(-\) division point is called primitive if \(N\) is its precise order in \(C/L\).

2) One can obviously combine the bijections of (3) to obtain a bijection
\[
\bigcup_{N' | N; N' \neq 1} \Gamma_1(N') \backslash \eta \rightarrow \{(C/L, Q) \mid N \cdot Q = 0, Q \neq 0\}/\text{isom}.
\]

Proof of the proposition: The mapping is well-defined, i.e. for \(A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma_1(N)\) and \(\tau' = A\tau\) one obtains the same image:
\[
(C/2\pi i (Z\tau' + Z), 2\pi i/N) = (C/2\pi i (Z\frac{a\tau + b}{c\tau + d} + Z), 2\pi i/N)
\]
\[
\cong (C/2\pi i (Z(a\tau + b) + Z(\sigma\tau + d)), 2\pi i(\sigma\tau + d)/N)
\]
\[
= (C/2\pi i (Z\tau + Z), 2\pi i/N),
\]
where we used that \(\frac{\sigma d + \tau b}{N} \equiv \frac{1}{N}\) modulo \(Z\tau + Z\) for \(A \in \Gamma_1(N)\).

On surjectivity: In order to construct a preimage of \((C/L, Q)\) we use the following

Lemma 7.5: For a primitive \(N\) \(-\) division point \(\omega\), there exists \(\bar{\omega} \in L\) and \(\omega' \equiv \omega (L)\) so that \(\omega\) and \(N \cdot \omega'\) are a \(Z\) \(-\) basis of \(L\).

Proof of the lemma: Let \(L = Z\omega_2 + Z\omega_1\) and \(\omega = |a\omega_1 + b\omega_2|/N\) with \(\alpha, \beta \in Z\) and \(\text{Im}(\omega_2/\omega_1) > 0\). Since \(\omega\) is primitive, we have \((\alpha, \beta, N) = 1\). Now use the easily checked

Lemma 7.6: For numbers \(\alpha, \beta, N\) with \((\alpha, \beta, N) = 1\), there exist \(\alpha'\) and \(\beta'\) with \((\alpha', \beta') \equiv (\alpha, \beta) (N)\) and \((\alpha', \beta') = 1\).

We therefore define \(\omega'\) by \(\omega' := \frac{\alpha\omega_1 + \beta\omega_2}{N}\) and choose \(\gamma, \delta \in Z\) with \(\alpha'\delta - \beta'\gamma = 1\). Then
\[
(\begin{pmatrix} N\omega' \\ \bar{\omega} \end{pmatrix}) = \begin{pmatrix} \alpha' & \beta' \\ \gamma & \delta \end{pmatrix} \begin{pmatrix} \omega_1 \\ \omega_2 \end{pmatrix}
\]
defines a basis \(N\omega'\) and \(\bar{\omega}\) of \(L\) with \(\text{Im}(\bar{\omega}/N\omega') > 0\).

Using Lemma 7.5, we write \((C/L, Q) = (C/L, \omega + L)\) as \((C/(Z\bar{\omega} + ZN\omega'), \omega' + L)\).

The latter is obviously isomorphic to \((C/2\pi i (Z\frac{\bar{\omega}}{N\omega'} + Z), 2\pi i/N)\). A preimage is therefore
\[
\tau = \bar{\omega}/(N\omega').
\]

On injectivity: Assume that
\[
(C/2\pi i (Z\bar{\tau} + Z), 2\pi i/N) \cong (C/2\pi i (Z\tau + Z), 2\pi i/N).
\]

Then there is a matrix \(A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{SL}_2(Z)\) so that \(\bar{\tau} = \frac{\alpha\tau + b}{\beta\tau + d}\). Hence
\[
(C/2\pi i (Z\bar{\tau} + Z), 2\pi i/N) \cong (C/2\pi i (Z(\alpha\tau + b) + Z(\beta\tau + d)), 2\pi i(\beta\tau + d)/N)
\]
\[
\cong (C/2\pi i (Z\tau + Z), 2\pi i(\beta\tau + d)/N).
\]
The latter is by assumption isomorphic to \((\mathbb{C}/(Z\tau + Z), 2\pi i/N)\). Therefore we must have \((c\tau + d)/N \equiv 1/N \mod Z\tau + Z\), and so \(A \in \Gamma_1(N)\).

The composite of the maps (2) and (3) gives a map

\[ \Gamma_1(N) \setminus \mathfrak{h} \rightarrow \mathcal{P}_N / \sim . \]

This map is induced by the correspondence which associates to each \(\tau \in \mathfrak{h}\) the polynomial \(P_\tau(x)\) determined by

\[ P_\tau\left( \frac{\partial_x f(\tau, x)}{f(\tau, x)} \right) = f(\tau, x)^{-N} + c^{2N} f(\tau, x)^N, \]

where \(f(\tau, x) = f(0, 1)(\tau, x)\) in the notation of Theorem 6.3 and

\[ c^{-2} = f(\tau, x) \cdot f(\tau, -x + 2\pi i/N). \]

This map is holomorphic in the sense that the coefficients of \(P_\tau(x)\) are holomorphic.

More precisely, one has

**Lemma 7.7:** The coefficient \(a_i(\tau)\) of \(P_\tau(X) = X^N + a_1(\tau)X^{N-1} + \cdots + a_N(\tau)\) is a modular form of weight \(i\) on \(\Gamma_1(N)\).

**Proof:** Let \(A_i(L, Q)\) denote the coefficients of the polynomial \(P(x)\) associated to the pair \((\mathbb{C}/L, Q)\). Clearly \(a_i(\tau) = A_i(2\pi i(Z\tau + Z), 2\pi i/N)\). By Theorem 7.1 we have \(A_i(\lambda L, \lambda Q) = \lambda^{-i} A_i(L, Q)\). The coefficient \(A_i(L, Q)\) is therefore a homogeneous lattice function of degree \(-i\). From the discussion at the end of part 3 of §2 we deduce that \(a_i\) transforms like a modular form of weight \(i\) on \(\Gamma_1(N)\).

The regularity of the \(a_i(\tau)\) follows from the fact that they are polynomials in certain modular forms on \(\Gamma_1(N)\). Indeed, by formulas (6)-(7) of §6 we have

\[ f(\tau, x) = x \cdot \exp\left( 2 \sum_{k=1}^{\infty} f_k(\tau) \frac{x^k}{k!} \right) - 2 \sum_{k=0}^{\infty} G_k(\tau) \frac{x^k}{k!} \]

with \(f_k\ (k \text{ odd})\) and \(f_k - G_k\ (k \text{ even})\) in \(M_k(\Gamma_1(N))\). The coefficients of the Laurent expansion of \(f(\tau, x)\) and \(\left( \frac{\partial_x f(\tau, x)}{f(\tau, x)} \right) f(\tau, x)\) around \(x = 0\) are therefore polynomials in the \(f_k\ (k \text{ odd})\) and \(f_k - G_k\ (k \text{ even})\). But then the coefficients of \(P_\tau(x)\) are also polynomials in these functions as follows easily from the differential equation for \(f(\tau, x)\) and a simple induction argument.

**7.2 The genus of the modular curve \(X_1(N)\)**

In the following let \(X_1(N)\) denote the Riemann surface

\[ X_1(N) := \overline{\Gamma_1(N) \setminus \mathfrak{h}} = \Gamma_1(N) \setminus \mathfrak{h} \cup \Gamma_1(N) \setminus P_1(Q). \]
For small values of $N$ one has for the genus $g(N)$ of $X_1(N)$:

<table>
<thead>
<tr>
<th>$N$</th>
<th>$1-10$</th>
<th>$11$</th>
<th>$12$</th>
<th>$13$</th>
<th>$14$</th>
<th>$15$</th>
<th>$16$</th>
<th>$17$</th>
<th>$18$</th>
<th>$\geq 19$</th>
<th>$\geq 31$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$g(N)$</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>2</td>
<td>1</td>
<td>1</td>
<td>2</td>
<td>5</td>
<td>2</td>
<td>$&gt;2$</td>
<td>$&gt;10$</td>
</tr>
</tbody>
</table>

**Genus $g(N)$ of $X_1(N)$**

In this section we derive a formula for the genus $g(N)$. For doing this we have to describe first of all the complex structure of $X_1(N)$, or, more generally, the complex structure of $X(\Gamma) := \Gamma \setminus (\mathfrak{h} \cup P_1(\mathbb{Q}))$ for any subgroup of finite index in $\text{SL}_2(\mathbb{Z})$ (for details compare [Sh71]). So let $\pi : \mathfrak{h} \cup P_1(\mathbb{Q}) \rightarrow X(\Gamma)$, be the natural projection. For each $\tau_0 \in \mathfrak{h} \cup P_1(\mathbb{Q})$ we define the following function:

$$t_{\tau_0}(\tau) = \begin{cases} \tau - \tau_0, & \text{if } \tau_0 \in \mathfrak{h}, \text{PT}\tau_0 = \{\text{id}\}, \\ \frac{\tau - \tau_0}{\nu}, & \text{if } \tau_0 \in \mathfrak{h}, |\text{PT}\tau_0| = \nu > 1, \\ e^{2\pi i A\tau/\nu}, & \text{for } A\tau_0 = \infty, A \in \text{SL}_2(\mathbb{Z}), \nu = |\text{PSL}_2(\mathbb{Z})\tau_0 : \text{PT}\tau_0|. \end{cases}$$

We make $\mathfrak{h} \cup P_1(\mathbb{Q})$ into a topological space by calling a subset $M$ open if for each point $\tau \in \mathfrak{h} \cap M$ an open neighborhood of $\tau$ in $\mathfrak{h}$ is contained in $M$, and for each $\tau \in P_1(\mathbb{Q}) \cap M$ the interior of an open disc touching $\tau$ and lying in $\mathfrak{h}$ is contained in $M$ (if $\tau = \infty$, then by definition such a circle is of the form $\{\tau' \in \mathfrak{h} \mid \text{Im}(\tau') > \epsilon > 0\}$). The set $X(\Gamma)$ is given the quotient topology. Then for each $p_0 = \pi(\tau_0) \in X(\Gamma)$ there exist open neighborhoods $U$ of $p_0$ and $V$ of $\tau_0$ so that $t_{\tau_0}([\pi]_V^{-1}(p))$ defines a homeomorphism of $U$ with a neighborhood of $0$. We call $(U, t)$ a chart at $p_0$. One verifies easily that a complex structure on $X(\Gamma)$ is thereby determined.

The natural mapping

$$\Xi : X_1(N) = \overline{\Gamma_1(N) \setminus \mathfrak{h}} \rightarrow \overline{\text{SL}_2(\mathbb{Z}) \setminus \mathfrak{h}}$$

is holomorphic and obviously of degree $\mu = [\text{PSL}_2(\mathbb{Z}) : \text{PG}\Gamma_1(N)]$. We leave it as an exercise (but compare formula (2) from §1) to verify that

$$\mu = \begin{cases} 3, & \text{if } N = 2, \\ \frac{1}{2} \cdot \varphi(N) \cdot \psi(N), & \text{otherwise}, \end{cases}$$

where $\varphi(N)$ denotes the Euler $\varphi$-function

$$\varphi(N) = \#\{a \in \mathbb{Z}/N\mathbb{Z} \mid (a, N) = 1\} = N \prod_{p|N} (1 - p^{-1})$$

and

$$\psi(N) = \#P_1(\mathbb{Z}/N\mathbb{Z}) = N \prod_{p|N} (1 + p^{-1}).$$
1.7 N-division points and $\Gamma_1(N) \backslash \mathfrak{h}$

To obtain explicit formulas for $g(N)$ we shall apply the Riemann-Hurwitz formula to the covering (4). For this we need information about possible fixed points and the number of cusps of $\Gamma_1(N)$ since these points are possible ramification points of the map (4).

**Lemma 7.8:** Any fixed point $\tau$ of $\Gamma \subset \text{SL}_2(\mathbb{Z})$ is equivalent under $\text{SL}_2(\mathbb{Z})$ to

1) $i$, and $\text{PT}_\tau$ is conjugate to $\langle \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \rangle$ in $\text{PSL}_2(\mathbb{Z})$ and has order 2, or

2) $\rho = e^{2\pi i/3}$, and $\text{PT}_\tau$ is conjugate to $\langle \begin{pmatrix} 0 & -1 \\ 1 & -1 \end{pmatrix} \rangle$ in $\text{PSL}_2(\mathbb{Z})$ and has order 3.

We leave the proof of Lemma 7.8 to the reader (or else cf. [Se70]). Note that the lemma implies in particular that any subgroup $\Gamma \subset \text{SL}_2(\mathbb{Z})$ of finite index has, modulo $\Gamma$, only finitely many inequivalent fixed points in $\mathfrak{h}$. Moreover it is clear that for any $\tau \in \mathfrak{h}$ one has $[\Gamma_\tau] \in \{1, 2, 3\}$.

**Lemma 7.9:** Let $\Gamma$ be a subgroup of finite index in $\text{SL}_2(\mathbb{Z})$, and let $g(\Gamma)$ denote the genus of $X(\Gamma) = \Gamma \backslash (\mathfrak{h} \cup \text{P}_1(\mathbb{Q}))$. Let $\mu = [\text{PSL}_2(\mathbb{Z}) : \text{PT}]$ and let $\nu_2$ and $\nu_3$ denote the number of inequivalent fixed points modulo $\Gamma$, which are equivalent modulo $\text{SL}_2(\mathbb{Z})$ to $i$, resp. $\rho = e^{2\pi i/3}$. Further, let $\nu_\infty$ be the number of cusps $\Gamma \backslash \text{P}_1(\mathbb{Q})$ of $\Gamma$. We then have:

$$g(\Gamma) = 1 + \frac{\mu}{12} - \frac{\nu_2}{4} - \frac{\nu_3}{3} - \frac{\nu_\infty}{2}.$$  

**Proof:** Let $e_1, \ldots, e_t$ be the branching orders of the natural map $\Xi : X(\Gamma) \to X(1)$ for the preimages of $\rho$. Since $e_j | 3$, $e_j$ is either 1 or 3 and so $\nu_3 = \# \{j \mid e_j = 1\}$. Further, $\mu = \sum_{j=1}^{t} e_j$ (if $A_i \in \text{SL}_2(\mathbb{Z})$ such that $A_1 \rho, \ldots, A_t \rho$ are representatives for the preimages of $\rho$ then $\bigcup_{i=1, \ldots, t} A_i \Gamma_\rho$ gives a complete set of representatives for $\Gamma \backslash \text{PSL}_2(\mathbb{Z})$) and therefore

$$\sum_{j=1}^{t} (e_j - 1) = \frac{2}{3}(\mu - \nu_3).$$

For $\infty$ we have analogously $\sum_{\Xi(P) = \infty} (e_P - 1) = \frac{1}{2}(\mu - \nu_2)$ and $\sum_{\Xi(P) = \infty} (e_P - 1) = \frac{1}{2}(\mu - \nu_\infty)$. The Riemann-Hurwitz formula therefore says

$$2g(\Gamma) - 2 = \mu(2g(1) - 2) + \sum_{P \in X(\Gamma)} (e_P - 1)$$

$$= -2\mu + \frac{2}{3}(\mu - \nu_2) + \frac{1}{2}(\mu - \nu_2) + (\mu - \nu_\infty),$$

where we have used $g(1) = 0$ (since $j(\tau) = E_4(\tau)/\Delta(\tau)$ has as sole singularity a pole of order one and so defines an isomorphism $X_1(1) \to \text{P}_1(\mathbb{C})$). Hence the assertion follows.

According to the preceding lemma we have to look for possible fixed points of $\Gamma_1(N)$:
Lemma 7.10: Let \( P \in \mathcal{H} \) be a fixed point of \( \Gamma_1(N) \). Then either

\[
N = 1 \quad \text{and} \quad P \equiv i(\Gamma_1(1)) \quad \text{or} \quad P \equiv \rho(\Gamma_1(1)),
\]

or

\[
N = 2 \quad \text{and} \quad P \equiv \frac{1}{2}(i+1)(\Gamma_1(2)),
\]

or

\[
N = 3 \quad \text{and} \quad P \equiv \frac{1}{6}(3+\sqrt{-3})(\Gamma_1(3)).
\]

In particular, for \( N \geq 4 \) the group \( \Gamma_1(N) \) has no fixed point.

Proof: For \( N = 1 \) we know this from Lemma 7.8. From this lemma it is also easily deduced that \( \text{tr}(A) \in \{\pm 1, 0\} \) for matrices \( A \in \Gamma_1(N) \). Now \( A \equiv \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \mod N \) and therefore we must have \( \text{tr}(A) \equiv 2 \mod N \). This condition cannot be fulfilled for \( N \geq 4 \).

In case \( N = 2 \) we must have \( \text{tr}(A) = 0 \), hence each fixed point is equivalent to \( i \) and of the form \( \frac{a}{c} \) with \( a \equiv 1 \mod 2 \) and \( c \equiv 0 \mod 2 \). By Lemma 7.9 we see, since the degree \( \mu \) of the covering \( \Xi \) is 3 in this case, that the number \( \nu_2 \) of fixed points is equal to 1 or 3. But since \( i \Gamma_1(2) \) is not a fixed point (the stabilizer \( \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \) of \( i \) does not lie in \( \Gamma_1(2) \), \( \nu_2 = 1 \) and there remains only one fixed point, namely \( \frac{1}{2} \Gamma_1(2) \).

Analogous considerations show that the fixed points of \( \Gamma_1(3) \) are conjugate to \( \rho \), and that likewise there is only one of them.

For the number of cusps we have the following

Lemma 7.11: The number \( \text{cu}(N) \) of cusps \( \Gamma_1(N) \backslash \Gamma_1(\mathbb{Q}) \) is given by

\[
\text{cu}(1) = 1, \quad \text{cu}(2) = 2, \quad \text{cu}(4) = 3,
\]

\[
\text{cu}(N) = \frac{1}{2} \sum_{t\mid N} \varphi(t) \varphi(N/t) \quad \text{otherwise.} \quad (5)
\]

Proof: For \( N = 1 \) this is clear. Now each element of \( \Gamma_1(\mathbb{Q}) \) can be written as a column vector \( \begin{pmatrix} a \\ c \end{pmatrix} \) for a matrix in \( \text{SL}_2(\mathbb{Z}) \). This representation is unique up to identification of \( \begin{pmatrix} a \\ c \end{pmatrix} \) with \( \begin{pmatrix} -a \\ c \end{pmatrix} \). In addition, \( \Gamma(N) \subset \text{SL}_2(\mathbb{Z}) \) is a normal subgroup and \( \text{SL}_2(\mathbb{Z})/\Gamma(N) \cong \text{SL}_2(\mathbb{Z}/N\mathbb{Z}) \). Therefore the cusps \( \Gamma(N) \backslash \Gamma_1(\mathbb{Q}) \) can be written uniquely (up to sign) as column vectors reduced modulo \( N \) (thereby \( (a,c,N) = 1 \)). Under the larger group \( \Gamma_1(N) \), \( \begin{pmatrix} a \\ c \end{pmatrix} \) and the column vector \( \begin{pmatrix} a+xc \\ c \end{pmatrix} = \begin{pmatrix} 1 & x \\ 0 & 1 \end{pmatrix} \begin{pmatrix} a \\ c \end{pmatrix} \) reduced modulo \( N \) are identified. One can therefore take as representatives of the cusps, up to sign, those \( \bar{c} \in \mathbb{Z}/N\mathbb{Z} \) and \( \bar{a} \in \mathbb{Z}/(c,N)\mathbb{Z} \) with \( (a,c,N) = 1 \).

For fixed \( t \mid N \) there are \( \varphi(N/t) \) possible \( \bar{c} \in \mathbb{Z}/N\mathbb{Z} \) for which \( t = (c,N) \). For each of these \( c \) there are \( \varphi(t) \) possible \( \bar{a} \in \mathbb{Z}/t\mathbb{Z} \) with \( (a,t) = 1 \). Hence there are \( \sum_{t|N} \varphi(t) \varphi(N/t) \) such pairs. Now the pairs \( \begin{pmatrix} a \\ c \end{pmatrix} \) and \( \begin{pmatrix} -a \\ c \end{pmatrix} \) must still be identified. We therefore halve this number apart from \( c = 0 \) or \( c = \frac{N}{2} \). For \( c = 0 \), \( N 
eq 2 \) we must also halve this number, since \( \begin{pmatrix} a \\ 0 \end{pmatrix} \) and \( \begin{pmatrix} -a \\ 0 \end{pmatrix} \) are identified, although \( a \neq -a \mod N \).
(consider \( t = N \) and \( 2a \neq N \), since \( (a, t) = 1 \)). For \( c = \frac{N}{2} \) and \( N \neq 4 \) analogous considerations apply. Formula (5) follows from this for \( N \neq 2, 4 \). For \( N = 2 \), resp. 4, one thereby makes two, resp. one identification too many, and must therefore add 1, resp. \( 1/2 \) to the result of (5).

We now have

**Theorem 7.12**: The genus \( g(N) \) of \( \Gamma_1(N) \) is 0 for \( N \leq 4 \), and is otherwise given by the formula

\[
g(N) = 1 + \frac{1}{24} \varphi(N)\psi(N) - \frac{1}{4} \cdot \sum_{t|N} \varphi(t)\varphi(N/t). \tag{6}
\]

**Remarks:**

1) For prime numbers \( N = p \geq 5 \) the formula (6) simplifies to

\[
g(p) = \frac{(p - 5)(p - 7)}{24}.
\]

2) Recall from the remark at the end of §1 that \( g(N) \) equals the dimension of \( S_2(\Gamma_1(N)) \). So the theorem gives us an explicit formula for the dimension of the space of cusp forms of weight 2 on \( \Gamma_1(N) \). More generally it is possible to show that for \( N \geq 5 \) and \( k \geq 2 \) one has

\[
dim M_k(\Gamma_1(N)) = \frac{\varphi(N)\psi(N)}{24} (k - 1) + \frac{1}{4} \sum_{t|N} \varphi(t)\varphi(N/t).
\]
Appendix II: The Dirac operator

by Paul Baum, Pennsylvania State University

1 The solution

Let \( E, F \) be two complex vector bundles over \( X \), where \( X \) is a compact \( C^\infty \)-manifold without boundary. Further, let \( D : C^\infty(E) \to C^\infty(F) \) be an elliptic differential operator; then the kernel and cokernel of \( D \) are finite dimensional vector spaces, and the index of \( D \), \( \text{ind} \,(D) := \dim C^\infty \ker (D) - \dim C^\infty \text{coker} \,(D) \) is well-defined. The Atiyah-Singer index theorem asserts that this index can be computed by a purely topological formula.

If \( X \) is complex analytic, \( E \) a holomorphic vector bundle over \( X \), and one chooses Hermitian structures for \( TX \) and \( E \), then the twisted differential operators \( \overline{\partial}_E \) and \( \overline{\partial}_E^* \) are defined. If one considers the differential operator

\[
\overline{\partial}_E + \overline{\partial}_E^* : C^\infty \left( \left( \sum_{j=0}^{\infty} \Lambda^{0,2j} TX \right) \otimes E \right) \to C^\infty \left( \left( \sum_{j=0}^{\infty} \Lambda^{0,2j+1} TX \right) \otimes E \right),
\]

then one obtains as a special case the Riemann-Roch formula of Hirzebruch:

\[
\chi(X,E) = (\text{ch} \,(E) \cdot \text{td} \,(TX))[X].
\]

An important elliptic operator is the Dirac operator. Consider \( \mathbb{R}^n \) with \( n = 2r \) or \( n = 2r + 1 \) and matrices \( E_1, \ldots, E_n \in M(2^r \times 2^r, \mathbb{C}) \) with the following properties (Clifford relations): Each \( E_j \) is a skew-adjoint matrix,

\[
E_j^2 = -I \quad \text{for } j = 1, \ldots, n
\]

and

\[
E_jE_k + E_kE_j = 0 \quad \text{for all } j \neq k.
\]

Here and in the following \( I \) denotes the identity matrix. For odd \( n \), we require that

\[
i^{r+1} E_1E_2\cdots E_n = I;
\]

for even \( n \) the \( E_j \) are to be block matrices of the form

\[
E_j = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \quad \text{and} \quad i^r E_1E_2\cdots E_n = \begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix}.
\]
Such matrices do indeed exist, and there is a simple

Algorithm for construction: For $n = 1$, $E_1 = (-i)$ is uniquely determined. If $n$ is odd, $r$ also increases by one when $n$ is raised to $n+1$, and $2^r \times 2^r$-matrices $\tilde{E}_1, \ldots, \tilde{E}_{n+1}$ with the desired properties are obtained from the matrices $E_1, \ldots, E_n$ for $n$ as follows:

$$\tilde{E}_j = \begin{pmatrix} 0 & E_j \\ E_j & 0 \end{pmatrix} \quad \text{for } j = 1, \ldots, n \quad \text{and} \quad \tilde{E}_{n+1} = \begin{pmatrix} 0 & -I \\ I & 0 \end{pmatrix}.$$  

Under passage from even $n$ to $n+1$, $r$ does not change; the new matrices are determined as follows:

$$\tilde{E}_j = E_j \quad \text{for } j = 1, \ldots, n \quad \text{and} \quad \tilde{E}_{n+1} = \begin{pmatrix} -i & 0 \\ 0 & i \end{pmatrix}.$$  

Remark: All entries of these matrices consist of the numbers $0$, $\pm 1$ and $\pm i$. In addition, these matrices are unique in the following sense: To any two systems $E_1, \ldots, E_n$ and $\tilde{E}_1, \ldots, \tilde{E}_n$ of matrices which satisfy the above properties, there exists a unitary matrix $U \in U(2^r)$ which conjugates the sets into one another:

$$\{\tilde{E}_j \mid j = 1, \ldots, n\} = \{UE_jU^{-1} \mid j = 1, \ldots, n\}.$$

Example:

$n = 1$: $E_1 = (-i)$.

$n = 2$: $E_1 = \begin{pmatrix} 0 & -i \\ -i & 0 \end{pmatrix}$, $E_2 = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$.

$n = 3$: $E_1 = \begin{pmatrix} 0 & -i \\ -i & 0 \end{pmatrix}$, $E_2 = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$, $E_3 = \begin{pmatrix} -i & 0 \\ 0 & i \end{pmatrix}$.

We are now in a position to define the Dirac operator for all $\mathbb{R}^n$.

Definition: The Dirac operator for $\mathbb{R}^n$ is defined by

$$D := \sum_{j=1}^{n} E_j \frac{\partial}{\partial x_j}.$$  

Examples:

$n = 1$: $D = -i \frac{\partial}{\partial x}$.

$n = 2$: $D = -2i \cdot \left( \begin{pmatrix} 0 & -\frac{\partial}{\partial x} \\ \frac{\partial}{\partial x} & 0 \end{pmatrix} \right)$ with $\tilde{\partial} = \frac{1}{2} \left( \frac{\partial}{\partial x_1} + i \frac{\partial}{\partial x_2} \right)$, $\tilde{\partial}^* = \frac{1}{2} \left( -\frac{\partial}{\partial x_1} + i \frac{\partial}{\partial x_2} \right)$.
Remark: The Dirac operator $D$ is formally self-adjoint, that is $\int \langle Df, g \rangle \, dx = \int \langle f, Dg \rangle \, dx$ for $C^\infty$-functions $f, g : \mathbb{R}^n \to \mathbb{C}^2r$ with compact support (here $\langle \cdot, \cdot \rangle$ is the standard scalar product on $\mathbb{C}^{2r}$). It is described by a Hermitian $2^r \times 2^r$ operator matrix. $D$ is a root of the Laplace operator $\Delta$ in the following sense: On the strength of the Clifford relations for the $E_j$, and since the $\frac{\partial}{\partial x_j}$ commute among themselves and with the $E_j$, we have

$$D^2 = -\Delta \cdot I \quad \text{with} \quad \Delta = \sum_{j=1}^n \frac{\partial^2}{\partial x_j^2}.$$ 

In order to construct the Dirac operator on a $C^\infty$-manifold $X$, one must place two further assumptions on $X$. Namely, the Stiefel-Whitney classes $w_j \in H^j(X; \mathbb{Z}/2\mathbb{Z})$ must satisfy:

1) $w_1 = 0$ (thus $X$ is orientable),

2) $w_2$ lies in the image of the reduction homomorphism $\rho : H^2(X; \mathbb{Z}) \to H^2(X; \mathbb{Z}/2\mathbb{Z})$.

When the conditions 1) and 2) are obeyed $M$ admits a so-called Spin$^c$-structure. For each fixed Spin$^c$-structure (e.g., complex manifolds have a canonical Spin$^c$-structure) one can construct a canonical first Chern class $c_1$. As an example, for complex manifolds the above assumption holds because $\rho(c_1) = w_2$. The ordinary first Chern class thereby coincides with the one obtained from the canonical Spin$^c$-structure. We use the identity

$$e^{x/2} \cdot \frac{x/2}{\sinh (x/2)} = \frac{x}{1 - e^{-x}}$$

in the ring of formal power series in order to define a Todd class for a manifold $X$ with a Spin$^c$-structure:

$$\text{td} (TX) := e^{c_1/2} \cdot \hat{A}(TX).$$

In the following paragraph, this Todd class solves the problem of computing the index of the Dirac operator.

2 The problem

Definition: Let $(V, \langle \cdot, \cdot \rangle)$ be an $n$-dimensional Euclidean vector space, and let $T(V) = \mathbb{R} \oplus V \oplus V \oplus V \oplus \cdots$ be the tensor algebra of $V$. The tensors of the form $\langle v, v \rangle \cdot 1 + v \otimes v$ generate a two-sided ideal $I \subset T(V)$. The quotient $\text{Cliff} (V, \langle \cdot, \cdot \rangle) = \text{Cliff} (V) := T(V)/I$ is the Clifford algebra of $V$ (with respect to $\langle \cdot, \cdot \rangle$).
Notice that $\mathbb{R}$ as well as $V$ is canonically embedded in $\text{Cliff}(V)$. In $\text{Cliff}(V)$ we denote the multiplication induced by "$\otimes$" simply with "$\cdot$". The sole relation between the elements can therefore be written as $v^2 = -(v, v) \cdot 1$. For an orthonormal basis $e_1, \ldots, e_n$ with respect to $\langle \cdot, \cdot \rangle$ we have the Clifford relations $e_j^2 = -1$ and $e_j \cdot e_k + e_k \cdot e_j = 0$ for $j \neq k$. The Clifford algebra has the $2^n$ basis elements $e_1^{e_1} \cdots e_n^{e_n}$ with $\varepsilon_j \in \{0, 1\}$. There is a canonical $\mathbb{R}$-vector space isomorphism

$$e_1^{e_1} \cdots e_n^{e_n} \rightarrow e_1^{e_1} \wedge \cdots \wedge e_n^{e_n}$$

of $\text{Cliff}(V)$ onto the exterior algebra $\Lambda(V)$.

**Definition:** For an orientable manifold $X$ of dimension $n = 2r$ or $n = 2r + 1$, a spinor system is a triple $(\varepsilon, \langle \cdot, \cdot \rangle, F)$, where $\varepsilon$ is an orientation of $X$ and $\langle \cdot, \cdot \rangle$ is a Riemannian metric on $X$. One can therefore construct a bundle $\text{Cliff}_C(X)$ of $\mathbb{C}$-algebras, whose fibres over points $P \in X$ are $\text{Cliff}(T_p X, \langle \cdot, \cdot \rangle) \otimes \mathbb{R} \mathbb{C}$. In addition, $F$ is a complex vector bundle satisfying the following conditions:

1) $\text{rk}_C F = 2^r$,
2) for all $P \in X$, $F_P$ is a Clifford module, i.e. there is a $\mathbb{C}$-linear operation $\cdot : \text{Cliff}_C(T_p X) \rightarrow \text{end}(F_P)$ for which $1$ acts on each fibre as the identity,
3) a Hermitian structure $\langle \cdot, \cdot \rangle$ is chosen on $F$, which defines an invariant metric in the following sense:
4) each tangent vector $v \in T_P(X) \subset \text{Cliff}_C(T_P X)$ acts as a skew-Hermitian mapping, $\bar{v}^* = -v$.

In addition, if $n$ is odd and $e_1, \ldots, e_n$ is a positively oriented orthonormal basis of $T_P$, the product $i^{r+1} e_1 \cdots e_n$ is to act as the identity on $F_P$. For even $n$, this additional condition need not hold.

In order to construct a spinor system, one needs precisely the assumptions on $X$ which were given in the previous paragraph: $w_1 = 0$ (orientability) and $w_2 \in \rho(H^2(X; \mathbb{Z}))$. Such a manifold together with a spinor system is called a Spin$^c$-manifold. The choice of the spinor system therefore determines the choice of a preimage $c_1 \in \rho^{-1}(w_2)$.

**Exercise:** Show that the condition on $w_2$ is necessary. Find a closed simply-connected manifold $X$ which is not a Spin$^c$-manifold.

**Remarks:**

1) In the complex-analytic case, $F = \sum_{j=0}^\infty \Lambda^j T^*$ defines the canonical spinor system.
2) For even $n$, let $e_1, \ldots, e_n$ be a positively oriented orthonormal basis of $T_P X$. We have $(i^* e_1 \cdots e_n)^2 = \text{id}$. The spinors $F$ therefore decompose under the action of $i^* e_1 \cdots e_n$ into the eigenspaces $F_+ \text{ of } +1$ and $F_- \text{ of } -1$.
3) Originally, $TM$ had GL$(n, \mathbb{R})$ as structure group. It can be reduced to GL$(n, \mathbb{R})$ by means of $\varepsilon$, and then to SO$(n)$ by means of the metric $\langle \cdot, \cdot \rangle$. Finally, it can be lifted to a Lie group Spin$^c$(n) lying over SO$(n)$ with fibre $S^1$. 
Choosing a spinor system is equivalent to choosing such a lifting of the structure group of $TM$ from $\text{GL}(n, \mathbb{R})$ to $\text{Spin}^c(n)$.

**Definition:** Let $X$ be an $n$-dimensional manifold with the spinor system $(\varepsilon, \langle \cdot, \cdot \rangle, F)$. A differential operator $D$ is called a Dirac operator if it satisfies the following axioms:

1) $D : C^\infty(F) \to C^\infty(F)$ is $\mathbb{C}$-linear.

2) The Leibniz rule holds: we have
   \[ D(f \cdot s) = (df) \cdot s + f(Ds) \]
   for sections $s \in C^\infty(F)$ and $C^\infty$-functions $f : X \to \mathbb{C}$. Here the cotangent vector $df$ is considered as a tangent vector via $\langle \cdot, \cdot \rangle$ (and then as an element of the Clifford algebra by the canonical embedding).

3) The operator $D$ is formally self-adjoint, i.e. for compactly supported sections $s_1, s_2 \in C^\infty_c(F|_{X\setminus \partial X})$ we have:
   \[ \int_X (Ds_1, s_2) \, d\text{vol} = \int_X (s_1, Ds_2) \, d\text{vol}. \]

4) For even $n$, $D$ must respect the eigenspace decomposition of $F$:
   \[ D^+ := D|_{F^+_e} : C^\infty(F^+) \to C^\infty(F^-) \]
   and \[ D^- := D|_{F^-_e} : C^\infty(F^-) \to C^\infty(F_+). \]

**Remark:** Such operators exist. $D$ is uniquely characterized by these axioms up to terms of lower order (in this case, these lower order terms are vector bundle maps). In particular, the symbol and the index are uniquely determined.

**Definition:** Let $X$ be a compact Spin$^c$-manifold without boundary, and $E$ a Hermitian $C^\infty$-vector bundle on $X$. Then a twisted Dirac operator $D_E$ exists,

\[ D_E : C^\infty(F \otimes E) \to C^\infty(F \otimes E). \]

It is elliptic and satisfies the axioms with $F$ replaced by $F \otimes E$.

In particular, for $X$ even-dimensional, the operator $D_E^+ : C^\infty(F^+_e \otimes E) \to C^\infty(F^- \otimes E)$ is defined and the solution of the first paragraph yields for its index

\[ \text{ind} \left( D_E^+ \right) = \langle \text{ch}(E) \cdot \text{td}(TX) \rangle[X]. \]

**Remark:** For a Spin$^c$-manifold, $c_1$ and therefore $\text{td}(TX)$ are determined by the choice of the spinor bundle. A different Spin$^c$-structure on the underlying manifold $X$ leads to a different Dirac operator (having in general a different index).

For $w_2 = 0$, one can choose $c_1 = 0$; The index of the Dirac operator $D$ for this Spin$^c$-structure is simply $\text{ind}(D) = \hat{A}(X)$. Thus for a spin manifold ($w_2 = 0$), the $\hat{A}(X)$-genus $\hat{A}(X)$ and the twisted $\hat{A}$-genera $\hat{A}(X, E)$ are integral.
Appendix III: Elliptic genera of level $N$ for complex manifolds

by Friedrich Hirzebruch

Corrections and improvements in sections 6 and 7 are due to Thomas Berger following a discussion with Serge Ochanine.

My lecture at the Como Conference was a survey on the theory of elliptic genera as developed by Ochanine, Landweber, Stong and Witten. A good global reference are the proceedings of the 1986 Princeton Conference [1]. In this contribution to the proceedings of the Como Conference I shall not reproduce my lecture, but rather sketch a theory of elliptic genera of level $N$ for compact complex manifolds which I presented in the last part of my course at the University of Bonn during the Wintersemester 1987/88. For a natural number $N > 1$ the elliptic genus of level $N$ of a compact complex manifold $M$ of dimension $d$ is a modular form of weight $d$ on the group $\Gamma_1(N)$. In the cusps of $\Gamma_1(N)$ the genus degenerates either to $\chi_y(M)/(1 + y)^d$ where $-y$ is an $N$-th root of unity different from 1 or to $\chi(M, K^{k/N})$ where $K$ is the canonical line bundle and $0 < k < N$. Here $\chi_y(M) = \sum_{p=0}^{d} \chi^p(M)y^p$ with $\chi^p(M) = \chi(M; \Omega^p) = \sum_{q=0}^{d} (-1)^q h^p\sigma$ is the $\chi_y$-genus introduced in [13] and $\chi(M, K^{k/N})$ is the genus with respect to the characteristic power series

$$\frac{x}{1 - e^{-x}} \cdot e^{-(k/N)x}$$

which equals the holomorphic Euler number of $M$ with coefficients in the line bundle $L^k$ provided $K = L^N$ (see [13]).

For $N = 2$ the genus is expressible in Pontrjagin numbers and hence defined for an oriented differentiable manifold $M$. The only possible value of $-y$ is $-1$ and the genus degenerates in the two cusps to

$$\chi_1(M)/2^d = \text{sign}(M)/2^d \quad (\dim_{\mathbb{R}} M = 2d)$$
or to

\[ \chi(M, K^{1/2}) = \hat{A}(M). \]

Only recently I realized that Witten in [19] studied also complex manifolds. His discussion includes the genus studied here, at least if one restricts attention to the cusps with specialization \( \chi(M, K^{k/N}) \).

In this report I shall also try to give an account of the rigidity theorems for complex manifolds with circle actions which for \( N = 2 \) are due to Taubes [18] and Witten with a new exposition by Bott [9]. These rigidity theorems hold if the first Chern class of \( M \) is divisible by \( N \), i.e. if a holomorphic line bundle \( L \) with \( L^N = K \) exists.

The results in this paper hold also for manifolds with a stable almost complex structure and for circle actions which preserve this structure. For simplicity we have formulated the results for complex manifolds only.

I would like to thank the students of my course Thomas Berger and Rainer Jung for writing the notes. Many thanks to Nils-Peter Skoruppa who lectured several times in my course when I was away and with whom I had helpful discussions on modular forms. After my course I had intensive discussions with Michael Atiyah on the rigidity theorem in Oxford and also with Don Zagier at the Max-Planck-Institut.

1. In the following \( N \) is a fixed natural number \( > 1 \), the “variable” \( x \) runs through the complex numbers. \( \mathsf{H} \) is the upper half-plane, \( \tau \in \mathsf{H} \) and \( q = e^{2\pi i \tau} \). For a lattice \( L \) in \( \mathbb{C} \) we consider the elliptic function \( g(x) \) with divisor \( N \cdot 0 - N \cdot \alpha \) where \( \alpha \in \mathbb{C} \) is an \( N \)-division point \( (\alpha \notin L, \ N\alpha \in L) \). The function \( g \) is uniquely determined by \( L \) and \( \alpha \) (regarded as element of \( \mathbb{C}/L \)) if we demand that the power series of \( g \) in the origin begins with \( x^N \). The function \( f(x) = g(x)^{1/N} \) is uniquely defined if we request \( f(x) = x + \text{higher terms} \). The function \( f \) is elliptic with respect to a sublattice \( L' \) of \( L \) whose index in \( L \) equals the order of \( \alpha \) as element of \( \mathbb{C}/L \). For \( \omega \in L \) the function \( f(x + \omega)/f(x) \) is constant and equals an \( N \)-th root of unity. After multiplying \( L \) with a non-vanishing complex number we can assume that

\[
L = 2\pi i(\mathbb{Z}\tau + \mathbb{Z}) \quad \text{and} \quad 0 \neq \alpha = 2\pi i\left(\frac{k}{N} \tau + \frac{l}{N}\right) \quad \text{with} \quad 0 \leq k < N \quad \text{and} \quad 0 \leq l < N. \tag{1}
\]

To write down a product development for \( f(x) \) in the case that \( L \) and \( \alpha \) are as in (1) we introduce the entire function\(^\dagger\)

\[
\Upsilon(x) = (1 - e^{-x}) \prod_{n=1}^{\infty} \frac{(1 - q^n e^{-x})(1 - q^n e^x)}{(1 - q^n)^2}
\]

\(^\dagger\) Note that the function \( \Upsilon(x) \) equals \( e^{-\pi/2} \Phi(x) \), where \( \Phi(x) \) is the function defined in Appendix I, §5.
which has zeroes of order 1 in the points of $L$. The function $\Upsilon(x)$ equals the Weierstraß sigma-function for $L$ up to a factor of the form $\exp (b_1 x + b_2 x^2)$. It can be proved easily that

$$f(x) = e^{\frac{k}{N} x} \Upsilon(x) \Upsilon(-\alpha)/\Upsilon(x - \alpha).$$

Namely, it suffices to check

$$\Upsilon(x + 2\pi i r) = -e^{-x} e^{-2\pi i r} \Upsilon(x).$$

For this replace in (2) the exponential $e^x$ by $\lambda$ and then substitute $\lambda$ by $\lambda q$ to see that the factor $-\lambda^{-1} q^{-1}$ comes out. In fact, we have (for $\zeta = e^{2\pi i/N}$)

$$f(x + 2\pi i) = \zeta^k f(x)$$
$$f(x + 2\pi i r) = \zeta^{-l} f(x)$$

(4)

The function $f(x)$ as belonging to $L$ and $\alpha$ (see (1)) degenerates for $q \to 0$ to a function $f_\infty(x)$.

We have

$$f_\infty(x) = e^{(k/N)x} (1 - e^{-x}) \text{ for } k > 0$$
$$f_\infty(x) = (1 - e^{-x})(1 - e^{x})/(1 - e^{-x}) \text{ for } k = 0.$$  

(5)

For reasons which are apparent from the introduction we put $e^y = -y$ for $k = 0$ and have in this case

$$f_\infty(x) = (1 - e^{-x})(1 + y)/(1 + ye^{-x}) \text{ with } -y = \zeta^l \neq 1.$$  

The involution $x \mapsto -x + \alpha$ interchanges the zeroes and poles of $f(x)$. Therefore,

$$f(x)f(-x + \alpha),$$

which is elliptic for $L$, is in fact a constant $\neq 0$. We write the constant as $c^{-2}$. Then $c^{2N}$ depends only on $L$ and the chosen $N$-division point as point of $\mathbb{C}/L$. If the lattice and $\alpha$ are normalized as in (1), then

$$f(x)f(-x + \alpha) = c^{(k/N)\alpha - \alpha} \Upsilon(-\alpha)^2 = c^{-2}$$

and

$$c^{2N} = \Upsilon(-\alpha)^{-2N} q^{\frac{4(k^2 - 1)}{N}} \zeta^{-kl}.$$  

(6)

The coefficients of the power series developments of $f(x)/x$, $x/f(x)$ and $xf'(x)/f(x)$ determine each other. If one replaces in such a series $x$ by $\lambda x$, one obtains the corresponding function for the lattice $\lambda^{-1} L$ and the $N$-division point $\lambda^{-1} \alpha$. Therefore the coefficient of $x^r$ in any of these series as function of the pair $L, \alpha$ with $\alpha \in \mathbb{C}/L$.
is homogeneous of degree \(-r\). Also \(c^{2N}\) is such a function of \(L\) and \(\alpha\). It is homogeneous of degree \(-2N\) and is related to Dedekind's \(\eta\)-function.

If the pair \(L, \alpha\) is chosen as in (1), then the coefficients of \(f(x)/x\) are indeed modular forms of weight \(r\) on the subgroup consisting of the matrices \(\begin{pmatrix} a & b \\ c & d \end{pmatrix}\) of \(\text{SL}_2(\mathbb{Z})\) which satisfy

\[
\begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} \alpha \\ \delta \end{pmatrix} \equiv \begin{pmatrix} \alpha \\ \delta \end{pmatrix} (N).
\]

Also \(c^{2N}\) is a modular form of weight \(2N\) on this group. (It still has to be shown that these forms are holomorphic in the cusps. See the next section.)

2. The classification of pairs \(L, \alpha\) where \(L\) is a lattice in \(\mathbb{C}\) and \(\alpha \in \mathbb{C}/L\) with \(N\alpha = 0\) (but \(\alpha \neq 0\)), up to multiplication by some complex number \(\lambda \neq 0\), leads to the introduction of the modular group

\[
\Gamma_1(N) = \{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{SL}_2(\mathbb{Z}) \mid c \equiv 0 (N), a \equiv d \equiv 1 (N) \}.
\]

If we assume that the \(N\)-division point has order \(N\) in \(\mathbb{C}/L\), then the classes of pairs \(L, \alpha\) are in one-to-one correspondence with the points of the modular curve \(\Gamma_1(N) \backslash \mathfrak{h}\) where \(\begin{pmatrix} a & b \\ c & d \end{pmatrix}\) acts on \(\mathfrak{h}\) by

\[
\tau \mapsto \frac{a \tau + b}{c \tau + d}.
\]

This follows from the fact that each pair \(L, \alpha\) is equivalent to a pair of type (1) with \(\alpha = 2\pi i/N\) (i.e. \(k = 0, \ell = 1\)). The coefficients of \(x^r\) in \(x/f(x), f(x)/x, x f'(x)/f(x)\) are modular forms of weight \(r\) on \(\Gamma_1(N)\). It remains to show that such a coefficient is holomorphic in each cusp of \(\Gamma_1(N) \backslash \mathfrak{h}\). Transforming \(f(x)\) (taken for the lattice (1) with \(\alpha = 2\pi i/N\)) to a cusp gives a function \(f(x)\) for some \(\alpha = 2\pi i \left( \frac{k}{N} \tau + \frac{1}{N} \right)\) and the same lattice\(^\dagger\). The formulas (2) and (3) show immediately that the \(q\)-development of each coefficient of \(f(x)\) has only non-negative powers of \(q\), fractional if \(k > 0\), but then a suitable root of \(q\) is the local uniformizing variable at the cusp.

The coefficients \(e_r\) of \(x f'(x)/f(x)\) are the Eisenstein series. Their \(q\)-developments (for \(k = 0\) and \(\ell = 1\)) for example can be read off from

\[
x f'(x) = \sum_{n=0}^{\infty} \frac{x q^n e^{-z}}{1 - q^n e^{-z}} - \sum_{n=1}^{\infty} \frac{x q^n e^z}{1 - q^n e^z} \in \sum_{n=0}^{\infty} \frac{x q^n e^{-z}}{1 - \zeta q^n e^{-z}} + \sum_{n=1}^{\infty} \frac{x q^n e^z}{1 - \zeta^{-1} q^n e^z}, \tag{7}
\]

Furthermore, \(e^{2N}\) (see (6)) is a modular form of weight \(2N\). For more detailed formulae concerning these \(q\)-developments in the case \(N = 2\) see [20]. For \(N > 2\) and \(N \neq 4\) the number of cusps of \(\Gamma_1(N)\) equals

\[
\frac{1}{2} \sum_{d|N} \varphi(d) \varphi \left( \frac{N}{d} \right),
\]

where \(\varphi\) is Euler's function\(^\ddagger\). Each cusp can be represented by several \(N\)-division points \(\alpha\) as in (1).

\(^\dagger\) Cf. Appendix I, Theorem 6.4 (ii).

\(^\ddagger\) Cf. Appendix I, Lemma 7.11.
3. Let $M_d$ be a compact complex manifold. The Chern classes $c_i$ of $M_d$ are elements of the $2i$-dimensional cohomology group $H^{2i}(M_d; \mathbb{Z})$. Let $c$ be the total Chern class of $M_d$ split up formally

$$c = \sum_{i=0}^{d} c_i = (1 + x_1)(1 + x_2) \cdots (1 + x_d)$$  \hfill (8)

where $x_1, x_2, \ldots, x_d$ can be regarded as 2-dimensional cohomology classes in some manifold fibered over $M_d$ (see [13], §13.3). Let $Q(x)$ be a fixed power series in the indeterminate $x$ starting with 1 whose coefficients are in some commutative ring containing $\mathbb{Z}$. Then

$$\varphi_Q(M_d) = Q(x_1)Q(x_2) \cdots Q(x_d)[M_d]$$  \hfill (9)

is the genus of $M_d$ with respect to the power series $Q$ where in (9) the symmetric expression $Q(x_1)Q(x_2) \cdots Q(x_d)$ is written in terms of the Chern classes in view of (8) and the 2d-dimensional component of this expression is evaluated on $M_d$ (compare [13], §10.2).

We define the elliptic genus $\varphi_N(M_d)$ by using the power series

$$Q(x) = \frac{x}{f(x)} = \frac{xY(x - \alpha)}{Y(x)Y(-\alpha)}$$  \hfill (10)

where $\alpha = 2\pi i/N$ and $f(x)$ is taken for the pair $L, \alpha$ with $L = 2\pi i(Z\tau + \mathbb{Z})$. We put again $\zeta = e^{2\pi i/N}$.

**Theorem:** The elliptic genus $\varphi_N(M_d)$ is a modular form of weight $d$ on the group $\Gamma_1(N)$. If one represents a cusp of $\Gamma_1(N)$ by $2\pi i(\frac{k}{N}\tau + \frac{1}{N})$ with $0 \leq k < N$ and $0 \leq l < N$, then the value of $\varphi_N(M_d)$ in this cusp equals

$$\chi(M_d, K^{k/N}) \quad \text{if} \quad k > 0$$

and

$$\chi_y(M_d)/(1 + y)^d \quad \text{if} \quad k = 0 \quad \text{and} \quad -y = \zeta^l.$$  

The theorem follows from the remarks in section 2 and from (5) by recalling that $\chi(M_d, K^{k/N})$ is the genus for the power series

$$\frac{x}{1 - e^{-x}} \cdot e^{-(k/N)x}$$

and $\chi_y(M_d)/(1 + y)^d$ is the genus for the power series

$$\frac{x}{1 - e^{-x}} \left(1 + ye^{-x}\right)/(1 + y),$$

see [13].
A genus can be defined also by a power series $Q(x)$ not beginning with 1 (we assume $Q(0) = a_0 \neq 0$). The definition is done by equation (9) again. Then $a^{-1}_0 Q(a_0 x)$ gives the same genus with a normalized power series (i.e. the constant term equals 1). We now define $\tilde{\varphi}_N(M_d)$ using the power series

$$\tilde{Q}(x) = \frac{x \Upsilon(x - \alpha)}{\Upsilon(x)}, \quad \alpha = 2\pi i / N.$$  \hspace{1cm} (11)

**Theorem:** The elliptic genus $\tilde{\varphi}_N(M_d)$ is a modular function on $\Gamma_1(N)$ if $d \equiv 0 \pmod{2N}$. We have

$$\varphi_N(M_d) = \tilde{\varphi}_N(M_d)(\Upsilon(-\alpha))^{-d} = \tilde{\varphi}_N(M_d) \cdot c^d.$$  

The result follows from the preceding theorem and the considerations in section 1 and 2 which show that $\Upsilon(-\alpha) = c^d$ is a modular form on $\Gamma_1(N)$ of weight $d$.

If $d$ is not divisible by $2N$, then

$$\tilde{\varphi}_N(M_d)^{2N/(d,2N)}$$  

is a modular function (here $(d,2N)$ is the greatest common divisor of $d$ and $2N$). One simply applies the theorem to the $2N/(d,2N)$-th power of $M_d$.

The function $\tilde{\varphi}_N$ has poles in the cusps represented by (1) with $k > 0$. The order of the pole is given by (6). Let us restrict to the case that $N$ is a prime. For $N = 2$ we have 2 cusps represented by $(k, l) = (0, 1)$ and $(k, l) = (1, 0)$. For $N$ odd, we have $2 \cdot \frac{N - 1}{2}$ cusps represented by $(k, l) = (0, l)$ and $1 \leq l \leq \frac{N - 1}{2}$ and $2 \cdot \frac{N - 1}{2}$ cusps represented by $(k, l) = (k, 0)$ and $1 \leq k \leq \frac{N - 1}{2}$. In the first kind of cusps the $q$-development of $\tilde{\varphi}_N(M_d)$ begins with the constant term $\chi_q(M_d)$ with $y = -\zeta^l$, in the latter case it starts with

$$\chi(M_d, K^{k/N}) \cdot q^{-k(N - k)d/2N}$$  

where $q$ is a local uniformizing parameter for this cusp of $\Gamma_1(N) \backslash \mathbb{H}$. (We have $q^N = q$ in (6)).

4. For a complex vector bundle $W$ of rank $r$ the exterior powers $\Lambda^i W$ and the symmetric powers $S^i W$ are well-defined vector bundles. Their Chern classes can be calculated from those of $W$. If $c_1, \ldots, c_r$ are the Chern classes of $W$ (where $c_i$ is in the $2i$-dimensional cohomology of the base space) and if we write formally

$$c = c_1 + c_2 + \cdots + c_r = (1 + x_1)(1 + x_2) \cdots (1 + x_r)$$  

then the Chern character (in the rational cohomology of the base space) is given by

$$ch(W) = e^{x_1} + e^{x_2} + \cdots + e^{x_r}.$$
Over the rationals $c$ and $\text{ch}$ determine each other. For the exterior powers we write with some indeterminate $t$

$$\Lambda_t(W) = \sum_{i=0}^{r} \Lambda_i W \cdot t^i$$

and for the symmetric powers

$$S_t(W) = \sum_{i=0}^{\infty} S_i W \cdot t^i.$$

Then we have for the Chern character

$$\text{ch} (\Lambda_t W) = \prod_{i=1}^{r} (1 + te^{\pi i}),$$

(12)

$$\text{ch} (S_t W) = \prod_{i=1}^{r} (1 - te^{\pi i})^{-1}.$$  

(13)

Formula (12) was often used in [13]. Formula (13) is, of course, a special case of the general method to calculate the Chern classes associated to given vector bundles by representations [7].

Following Witten's idea (see [19]) we write the elliptic genus $\tilde{\varphi}_N (M_d)$, or rather its $q$-development in the standard cusp, in the form

$$\tilde{\varphi}_N (M_d) = \sum_{n=0}^{\infty} \chi_y (M_d, R_n) q^n.$$  

(14)

Here, as before, $-y = \zeta = e^{2\pi i / N}$. Furthermore $R_n$ is a virtual vector bundle associated to the complex tangent bundle of $M_d$ by a virtual representation of $\text{GL}(d, \mathbb{C})$ (with coefficients in $\mathbb{Z}[\zeta]$).

For a vector bundle $W$ the polynomial $\chi_y (M_d, W)$ is defined in [13]. We have, if $T$ is the tangent bundle of $M_d$,

$$\chi_y (M_d, W) = \sum_{p=0}^{d} \chi (M_d, \Lambda^p T^* \otimes W) q^p.$$

We now can specify the $R_n$ in (14). Let us recall that $\tilde{\varphi}_N (M_d)$ is the genus belonging to the power series (11)

$$\bar{Q}(x) = \frac{x}{1 - e^{-x}} \prod_{n=1}^{\infty} \frac{1 + y q^n e^{-x}}{1 - q^n e^{-x}}.$$  

(15)
Therefore (by (12) and (13))
\[
\sum_{n=0}^{\infty} R_n q^n = \prod_{n=1}^{\infty} \Lambda_{y^n} T^* \cdot \prod_{n=1}^{\infty} \Lambda_{y^{-1} q^n} T \cdot \prod_{n=1}^{\infty} S_{q^n} (T + T^*)
\]
(with \(-y = \zeta = e^{2\pi i/N}\)).

We have
\[
R_0 = 1, \quad R_1 = (1 - \zeta) T^* + (1 - \zeta^{-1}) T
\]
Modulo the ideal \((1 - \zeta)\) of \(\mathbb{Z}[\zeta]\), the elliptic genus \(\tilde{\varphi}_N (M_d)\) equals the Euler-Poincaré number \(e(M_d)\).

According to Witten’s philosophy (compare also [2] and [3]) if we had a \(\chi_y\)-operator on the loop space \(\mathcal{L}M_d\) of \(M_d\), we could try to calculate (or define) its equivariant \(\chi_y\)-genus for the natural \(S^1\)-action on \(\mathcal{L}M_d\) with \(q \in S^1\) \((q = e^{2\pi i \tau}, \tau \in \mathbb{R})\) by the Atiyah-Bott-Singer ([4], [6]) fixed point theorem (fixed point set \(M_d\) (constant loops) in \(\mathcal{L}M_d\)). The result for the equivariant \(\chi_y\)-genus \(\chi_y (\mathcal{L}M_d, q)\) would be that it is the genus with respect to the power series
\[
x \prod_{n=-\infty}^{\infty} \frac{1 + y q^n e^{-z}}{1 - q^n e^{-z}}
\]
This does not make sense as a power series in \(q\), but formal manipulations bring \(\chi_y (\mathcal{L}M_d, q)\) to the genus \(\tilde{\varphi}_N (M_d)\) belonging to \(\tilde{Q}(x)\) (see (15)) provided \((-y)^d = 1\).

Observe that (15) is a meromorphic function in the two variables \(x\) and \(q\) where \((x, q) \in \mathbb{C}^2\) and \(|q| < 1\).

5. The genus \(\tilde{\varphi}_n (M_d)\) has in the standard cusp a development whose coefficients are integral. They are elements of \(\mathbb{Z}[\zeta]\). See formula (14). In the cusp (represented by (1) with \(0 < k < N\)) this is not so. The coefficients are of the form
\[
\chi (M_d, K^{k/N} \otimes W_n),
\]
where \(W_n\) is a virtual vector bundle associated to the tangent bundle by a virtual representation of \(\text{GL}(d, \mathbb{C})\) with coefficients in \(\mathbb{Z}[\zeta]\). The \(W_n\) can be calculated using (3). These coefficients are in general not integral. If, however, the first Chern class \(c_1\) of \(M_d\) is divisible by \(N\) they are integral. This divisibility condition is equivalent to the existence of a holomorphic complex line bundle with \(L^N = K\) and the coefficients
\[
\chi (M_d, L^k \otimes W_n)
\]
become “Riemann-Roch numbers” [13] which are integral.

**Theorem:** If the first Chern class \(c_1\) of a complex manifold \(M_d\) is divisible by \(N\), then the coefficients of the \(q\)-developments of the genus \(\tilde{\varphi}_N (M_d)\) in all cusps (given by (1)) are integral \((\in \mathbb{Z}[\zeta])\); for the elliptic genus \(\varphi_N (M_d)\) the coefficients are integral in a cusp with \(k > 0\), in the cusps with \(k = 0\) they become integral after multiplication with \((1 - \zeta)^d\).
6. Let \( M_d \) be a compact complex manifold together with an action of the circle \( S^1 \) on \( M_d \) by holomorphic maps. We write elements of the circle as \( \lambda = e^{2\pi i z} \) where \( z \in \mathbb{R}/\mathbb{Z} \). The group \( S^1 \) acts on the virtual bundles \( R_n \) (see (16)). It also acts on the "cohomology group"

\[
H^q(M_d; \Lambda^{P\ast} \otimes R_n)
\]

which is in fact a formal direct sum of cohomology groups \( H^q(M_d; \Lambda^{P\ast} \otimes W) \) with coefficients in \( \mathbb{Z} \). Since \( S^1 \) acts, we get from (17) (considered equivariantly) a character of \( S^1 \), i.e. a finite Laurent series in \( \lambda \). Taking alternating sums over \( q \) in (17) gives us a character

\[
\chi(M_d; \Lambda^{P\ast} \otimes R_n, \lambda)
\]

and finally (with \( -y = e^{2\pi i/N} \))

\[
\chi_y(M_d, R_n, \lambda) = \sum_{p=0}^{d} \chi(M_d, \Lambda^{P\ast} \otimes R_n, \lambda) y^p
\]

and

\[
\tilde{\varphi}_N(M_d, \lambda) = \sum_{n=0}^{\infty} \chi_y(M_d, R_n, \lambda) q^n.
\]

It may be more convenient to return to our elliptic genus \( \varphi_N \) with characteristic power series \( Q(x) \) (see (10)) and consider it equivariantly

\[
\varphi_N(M_d, \lambda) = \tilde{\varphi}_N(M_d, \lambda) \cdot \chi(-\alpha)^{-d} = \sum_{n=0}^{\infty} \chi_y(M_d, S_n, \lambda) q^n
\]

where the \( S_n \) are virtual bundles (coefficients in \( Q(\zeta) \)). We can calculate \( \varphi_N(M_d, \lambda) \) using the Atiyah-Bott-Singer fixed point theorem (holomorphic Lefschetz theorem [6], p. 566). Before doing this some remarks concerning the fixed point set \( M_d^{S^1} \) are necessary. The set \( M_d^{S^1} \) is a smooth submanifold of \( M_d \) being a disjoint union of connected submanifolds of various dimensions. For each fixed point \( p \), the circle acts in the tangent space \( T_p \), hence integers \( m_1, \ldots, m_d \) are defined such that \( \lambda \in S^1 \) acts by the diagonal matrix \((\lambda^{m_1}, \lambda^{m_2}, \ldots, \lambda^{m_d})\). For each \( r \in \mathbb{Z} \) we consider those \( m_r \) which are equal to \( r \). This leads to the eigenspace \( E_r \) of \( T_p \). Of course, \( E_0 \) is the tangent space in \( p \) of the connected component of \( M_d^{S^1} \) to which \( p \) belongs. The numbers \( m_1, \ldots, m_d \) (well defined up to order) depend only on the component of \( M_d^{S^1} \). Over each component we have eigenspace bundles, also denotes by \( E_r \).
The characteristic power series of the elliptic genus $\varphi_N$ is given in (10) in the form $Q(x) = x/f(x)$. For the fixed point theorem we need $1/f(x)$. We put

$$F(x) = 1/f(x) = \frac{\Upsilon(x-\alpha)}{\Upsilon(x)\Upsilon(-\alpha)} \quad (20)$$

We shall now give a formula for $\varphi_N(M_d, \lambda)$ using the holomorphic Lefschetz theorem writing it down in short hand form which will need some explanation:

Let $\nu$ be an index for the connected components $(M_d^{S^1})_\nu$ of the fixed point set $M_d^{S^1}$. Then

$$\varphi_N(M_d, \lambda) = \sum_\nu \varphi_N(M_d, \lambda)_\nu \quad (21)$$

and

$$\varphi_N(M_d, \lambda)_\nu = (e_0 \cdot F(x_1 + 2\pi im_1 z) \cdots F(x_d + 2\pi im_d z))[\{(M_d^{S^1})_\nu\}] \quad (22)$$

where $e_0$ is the product of those $x_i$ for which $m_i = 0$. Recall $\lambda = e^{2\pi i \tau}$. Formulas (21) and (22) have the following meaning. For each component of the fixed point set, $e_0$ is the Euler class (highest Chern class) of its tangent bundle $E_0$, the formal roots of the total Chern class of $E_0$ are the $x_i$ with $m_i = 0$. The $x_i$ with $m_i = r \neq 0$ are the formal roots of the total Chern class of the eigenspace bundle $E_r$ over the component. Thus for $E_0$ one uses in the above product $xF(x) = Q(x)$ and for $E_r$ ($r \neq 0$) the function $F(x + 2\pi i r z)$ which for $\tau z \notin \mathbb{Z} + \mathbb{Z}$ has no pole for $x = 0$ (and we use a general $z$) and hence is a power series in $x$. Observe that the rotation numbers $(m_1, \ldots, m_d)$ depend on the component and also the meaning of the $x_i$ which are the formal roots of the total Chern class restricted to the component. Then one evaluates the expression in (22) on the component and obtains a power series $\varphi_N(M_d, \lambda)_\nu$ in $q$

$$\varphi_N(M_d, \lambda)_\nu = \sum_{n=0}^{\infty} c_{\nu,n} q^n \quad (23)$$

with coefficients $c_{\nu,n}$ that are meromorphic functions in $\lambda \in \mathbb{C}^*$ and have possible poles only on $S^1$. Considering (19) we let $c_n := \chi_g(M_d, S^1, \lambda)$ so that $c_n$ is also a meromorphic function in $\lambda \in \mathbb{C}^*$, in fact it is a finite Laurent series (so holomorphic). From the Lefschetz formula we know that $c_n(\lambda) = \sum_\nu c_{\nu,n}(\lambda)$ for $\lambda$ any topological generator of $S^1$ and so we get

$$c_n = \sum_\nu c_{\nu,n} \quad (24)$$

as meromorphic functions.

Looking closer at (22) we see that all $c_{\nu,n}$ have possible poles only at $\lambda^m = 1$ for any rotation number $m$. Furthermore the local term (23) converges for $|q| < 1$ and $|q|^{1/M} < |\lambda| < |q|^{-1/M}$ ($M = \max_i \{m_i\}$) to a meromorphic function and this function has a meromorphic extension to $\mathbb{C}^*$.  

According to (4) our function $F(x)$ has the property

$$F(x + 2\pi i) = F(x), \quad F(x + 2\pi i \tau) = \zeta F(x)$$

(25)

where $\zeta = e^{2\pi i / N}$. So the meromorphic extension of $\varphi_N(M_d, \lambda)_\nu$ is an elliptic function for the lattice $ZN \tau + Z$. More precisely

$$\varphi_N(M_d, \lambda q)_\nu = \varphi_N(M_d, e^{2\pi i (x + i \tau)})_\nu$$

$$= \zeta^{m_1 + \cdots + m_d} \varphi_N(M_d, \lambda)_\nu$$

(26)

The exponent $m_1 + \cdots + m_d$ depends on $\nu$, even the residue class of the exponent modulo $N$ depends on $\nu$ in general.

**Definition:** The $S^1$-action on $M_d$ is called **$N$-balanced** if for the components $(M_{d^1})_\nu$ of the fixed point set the residue class of $m_1 + \cdots + m_d$ modulo $N$ does not depend on $\nu$. If the action is $N$-balanced, the common residue class of $m_1 + \cdots + m_d$ is called the **type of the action** and denoted by $t$.

From formula (24) we immediately get that $\varphi_N(M_d, \lambda) = \sum_{n=0}^{\infty} c_n q^n$ also converges on some small annulus containing $S^1$ (depending on the rotation numbers) to a meromorphic function that has a meromorphic extension to $\mathbb{C}^*$. In this sense formula (21) is an identity between meromorphic functions on $\mathbb{C}^*$. In particular we see that $\varphi_N(M_d, \lambda)$ is an elliptic function for the lattice $ZN \tau + Z$. For an $N$-balanced action (26) finally yields the

**Theorem:** For an $N$-balanced $S^1$-action of type $t$ on the complex manifold $M_d$, the equivariant elliptic genus $\varphi_N(M_d, \lambda)$ with $\lambda = e^{2\pi i z}$ is an elliptic function for the lattice $Z \cdot N \tau + Z$ which satisfies

$$\varphi_N(M_d, \lambda q) = \varphi_N(M_d, e^{2\pi i (x + i \tau)})$$

$$= \zeta^t \varphi_N(M_d, \lambda).$$

(27)

**Remark:** Of course, $\varphi_N$ can be regarded as a function of $\tau$ and $z$. In $\tau$ it is a modular form of weight $d$. In fact, $\varphi_N$ is a meromorphic Jacobi form on $\Gamma_1(N)$ of weight $d$ and index 0 (see [11]).

7. We now shall approach the rigidity theorems which under certain conditions state that the finite Laurent series $\chi_y(M_d, R_n, \lambda)$ (see (16) and (18)) do not depend on $\lambda$. (Recall $-y = e^{2\pi i / N}$). This rigidity means that the elliptic function $\varphi_N(M_d, \lambda)$ of the preceding theorem is a constant (see (19)), i.e. we have to show that it has no poles. The rigidity results were not included in my course at the University of Bonn. When Michael Atiyah came to Bonn in February 1988 he explained to me Bott’s approach [9] and that it is rather close to our old paper [5] and we discussed it in Oxford in March. I did not study Taubes’s paper [18] in detail, but rather looked in Bott’s report [9]. Then
I carried out the proof for the level \( N \) case during my visit in Cambridge (England) in March 1988 as a guest of Robinson college.

Let us consider \( \varphi_N(M_{d}, \lambda) \) and the local terms \( \varphi_N(M_{d}, \lambda)_\nu \) as functions of \( \lambda \) for fixed \( q \) with \( |q| < 1 \). From section 6 we know that they are meromorphic for \( \lambda \in \mathbb{C}^* \). From (22) we see that \( \varphi_N(M_{d}, \lambda)_\nu \) has poles only for \( mz \in \mathbb{Z} \mathbb{R} + \mathbb{Z} \) where \( m \) is a rotation number \( \neq 0 \) occurring for the component \( \left( M_{d, \nu}^\mathbb{R} \right)_\nu \). Of course, \( mz \in \mathbb{Z} \mathbb{R} + \mathbb{Z} \) means \( \lambda^m = q^n \) where \( n \in \mathbb{Z} \). So from (21), \( \varphi_N(M_{d}, \lambda) \) has possible poles only for \( \lambda^m = q^n \) where \( m \) is any rotation number.

Now choose \( \lambda_0 \in S^1 \) with \( \lambda_0^m = 1 \) for some rotation number \( m \). If \( q \) is fixed with \( |q| < 1 \), then there is a neighborhood \( U \) of \( \lambda_0 \) in \( \mathbb{C}^* \) such that no point \( (\lambda, q) \) with \( \lambda \in U \setminus \{ \lambda_0 \} \) lies on one of the curves \( \lambda^m = q^n \) and that \( \sum_{n=0}^{\infty} c_{\nu,n} q^n \) as well as \( \sum_{n=0}^{\infty} c_{\nu,n} q^n \) converge on \( U \) with \( c_{\nu,n} \) and \( c_n \) as in section 6. Furthermore \( c_n = \sum_{\nu} c_{\nu,n} \) is holomorphic on \( U \) (since it is a finite Laurent series) and the only possible pole of \( c_{\nu,n} \) on \( U \) is \( \lambda_0 \).

**Lemma:** Let \( U \) be a domain, \( \lambda_0 \in U \). Consider meromorphic functions \( b_{\nu,n} \) on \( U \) for \( \nu \) in a finite set \( S \) and \( n \in \mathbb{N} \) with the following properties:

1) \( b_{\nu,n} \) is holomorphic in \( U \setminus \{ \lambda_0 \} \),
2) \( b_n := \sum_{\nu \in S} b_{\nu,n} \) is holomorphic in \( \lambda_0 \),
3) \( \sum_{n=0}^{\infty} b_{\nu,n} \) converges compactly in \( U \setminus \{ \lambda_0 \} \) for any \( \nu \in S \).

Then \( \sum_{n=0}^{\infty} b_n \) converges compactly in \( U \) and is a holomorphic extension of \( \sum_{\nu \in S} \sum_{n=0}^{\infty} b_{\nu,n} \) on \( U \setminus \{ \lambda_0 \} \).

**Proof of the lemma:** Let \( K \) be a compact set with \( \lambda_0 \) in its interior and let \( L \) be a small closed disc around \( \lambda_0 \) with \( L \subset K \). For \( 0 \leq k \leq m \) we have

\[
| \sum_{n=k}^{m} \left( \sum_{\nu \in S} b_{\nu,n} \right) |_K = | \sum_{n=k}^{m} \left( \sum_{\nu \in S} b_{\nu,n} \right) |_{\partial K}
\leq | \sum_{n=k}^{m} \left( \sum_{\nu \in S} b_{\nu,n} \right) |_{\partial (K \setminus L)}
= | \sum_{n=k}^{m} \left( \sum_{\nu \in S} b_{\nu,n} \right) |_{K \setminus \overline{L}}
= \sum_{\nu \in S} \sum_{n=k}^{m} | b_{\nu,n} |_{K \setminus \overline{L}}
\leq \sum_{\nu \in S} \sum_{n=k}^{m} | b_{\nu,n} |_{\overline{K \setminus \overline{L}}}.
\]

The first equation is due to the maximum principle, the second one comes from \( \overline{L} \subset \overline{K} \), the third one is again the maximum principle, the fourth one follows from holomorphicity.
III Elliptic genera of level $N$ for complex manifolds

of $b_{v,n}$ on $K \setminus L$. Let now be $\epsilon > 0$ and put $\epsilon' := \epsilon/\|S\|$. There exist $n_v$ such that for $m$, $k \geq n_v$ we have $|\sum_{n=k}^{m} b_{v,n}|_{K \setminus L} < \epsilon'$. Thus we finally see that $|\sum_{n=k}^{m} b_{v,n}|_{K \setminus L} < \epsilon$ for any $m$, $k \geq n_0 := \max_v \{n_v\}$.

Using this lemma with $b_{v,n} := c_{v,n} q^n$ we immediately get that $\phi_N(M_d,\lambda) = \sum_{n=0}^{\infty} c_n q^n$ has no poles on $S^1$.

An $S^1$-action is semi-free-semi-free action (i.e. the fixed point set of any $\lambda \in S^1$, $\lambda \neq 1$, equals $M^S_d$) if and only if all non-vanishing rotation numbers $m$ equal $\pm 1$. Therefore, for a semi-free action, $M^S_d$ can have poles only for $\lambda = q^n$ with $n \in \mathbb{Z}$.

**Theorem:** For an $N$-balanced semi-free $S^1$-action of type $t$ on the complex manifold $M_d$, the equivariant elliptic genus $\phi_N(M_d,\lambda)$ does not depend on $\lambda$. It equals the elliptic genus $\phi_N(M_d)$.

If $t \neq 0 (N)$, then $\phi_N(M_d) = 0$. (Compare [14] and [15].)

**Proof:** By the lemma, there is no pole for $\lambda = 1$. Because of (25) there are no poles for $\lambda = q^n$. The vanishing of $\phi_N(M_d)$ follows also from (25).

8. Let $M_d$ be a complex manifold with first Chern class $c_1 \in H^2(M_d; \mathbb{Z})$ divisible by $N$. The importance of this condition was already apparent in section 5. We choose a holomorphic line bundle $L$ with $L^N = K$. Now suppose we have an $S^1$-action on $M_d$. Consider the $N$-fold covering $S^1 \to S^1$ with $\mu \mapsto \lambda = \mu^N$. Then $\mu$ acts on $M_d$ and $K$ through $\lambda$. This action can be lifted to $L$. If $p$ is a fixed point of the given $S^1$-action with rotation numbers $m_1, m_2, \ldots, m_d$, then $\mu$ acts in the fibre $L_p$ by $\mu^{-(m_1+\cdots+m_d)}$. However, if $\mu = \zeta = e^{2\pi i/m}$, then it operates trivially on $M_d$. Therefore the action of $\zeta$ in each fibre of $L$ is by multiplication with $\zeta^{-t}$, where $t$ is a residue class modulo $N$ which does not depend on the base point of the fibre. (Assume that $M_d$ is connected.) It follows that the action is $N$-balanced of type $t$ (see the definition in section 6).

The condition $c_1 \equiv 0 (N)$ implies a stronger property than $N$-balanced. Let $G_m \subset S^1$ be the group of $m$-th roots of unity. The fixed point set of $G_m$ is a submanifold of $M_d$ which includes $M^S_d$ and is strictly larger if and only if there is a rotation number divisible by $m$. We denote the fixed point set of $G_m$ by $M^S_m$. There is the map $S^1 \to S^1$ with $\mu \mapsto \lambda = \mu^N$ which we considered before. Hence any $\mu \in S^1$ with $\mu^m = 1$ operates trivially on $M^S_m$, however it operates on every fibre $L_p$ ($p \in M^S_m$) by multiplication with some $mN$-th root of unity which only depends on the connected component of $M^S_m$ which contains $p$. Since $\mu$ acts on $L_p$ (for $p \in M^S_d$) by $\mu^{-(m_1+\cdots+m_d)}$ where the $m_j$ are the rotation numbers of the action in $p$, it follows that the residue class of $m_1 + \cdots + m_d$ modulo $mN$ depends only on the connected components of $M^S_m$ and not on the components of $M^S_d$ contained in them.

Let $X$ be a connected component of $M^S_m$ and $(M^S_d)_p$ a component of $M^S_d$ contained in $X$ with rotation numbers $m_1, \ldots, m_d$. Over $X$ the tangent bundle $T$ of $M_d$ splits into vector bundles $E_k$ where $k = 0, 1, \ldots, m - 1$ and the action of $G_m$ in $E_k$ is by multiplication with $\lambda^k$ if $\lambda \in G_m$. Of course, $E_0$ is the tangent bundle of $X$. 
Over \((M_d^{S^1})_\nu\) we have
\[ E_k = \sum_{r \equiv k \, (m)} B_r \] (see section 6).
\(28\)

We write the rotation numbers in the following form
\[ m_i = r_i m + k_i \quad \text{where} \quad k_i = 0, \ldots, m - 1. \]
\(29\)

Since the integer \(\sum_{i=0}^d k_i = \sum_{k=0}^{m-1} h \cdot \text{rk} \, \overline{E}_k\) depends only on \(X\), we see that \(m \cdot \sum_{i=0}^d r_i \) modulo \(m N\) depends only on \(X\). Hence, \(\sum_{i=0}^d r_i \) modulo \(N\) depends only on \(X\) and not on the components \((M_d^{S^1})_\nu\) contained in it. We put
\[ t(m, X) := \sum_{i=0}^d r_i \mod N. \]
\(30\)

Of course, \(t(1, M_d)\) is the type \(t\) of the action (for connected \(M_d\)).

9. Let \(M_d\) be a compact complex manifold with \(c_1 \equiv 0 \,(N)\). We assume that we have an \(S^1\)-action and wish to show that the elliptic function \(\varphi_N(M_d, \lambda)\) has no poles. Let \(X\) be a connected component of \(M_d^{S^1}\) (see section 8). We define
\[ \varphi_N(X, \lambda) := \sum_\nu \varphi_N(M_d, \lambda)_\nu \]
\(31\)

where the summation is over those connected components \((M_d^{S^1})_\nu\) which are contained in \(X\) (see (21)). This is a shorthand notation. Do not confuse (31) with the elliptic genus of \(X\). Let \((M_d^{S^1})_\nu\) have the rotation numbers \(m_1, \ldots, m_d\). According to (22) we have
\[ \varphi_N(M_d, \lambda)^{(s/m)} = (e_0 F(x_1 + 2\pi im_1 z) \cdots F(x_d + 2\pi im_d z))[(M_d^{S^1})_\nu]. \]
\(32\)

Let \(s\) be an integer and replace in (32) the variable \(z\) by \(z + \frac{s}{m} \tau\) (in other words, replace \(\lambda\) by \(\lambda \cdot q^{s/m}\)), then \(\varphi_N(M_d, \lambda q^{s/m})_\nu\) is again an elliptic function in \(z\) for the lattice \(Z \cdot N \tau + Z\). It follows from (25), (29) and (30) that
\[ \varphi_N(M_d, \lambda q^{s/m}) = \zeta^{s t(m, X)} \left( e_0 \prod_{j=1}^d F(x_j + 2\pi im_j z + 2\pi i \frac{s k_j}{m} \tau) \right)[(M_d^{S^1})_\nu]. \]
\(33\)

If we write down the \(q\)-development of the right hand side of (33) (with fractional powers of \(q\)) we see that \(\varphi_N(X, \lambda q^{s/m})\) is of the form
\[ \varphi_N(X, \lambda q^{s/m}) = \sum_{n=0}^\infty \chi_n(X, S_n, \lambda) q^n / m \]
\(34\)

where the \(S_n\) are virtual equivariant bundles constructed from the bundles \(\overline{E}_k\) over \(X\). For \(m = 1\) we come back to (19). The elliptic function (34) has no poles for \(|\lambda| = 1\). We use again the lemma in section 7.
10. We are now able to prove the rigidity theorem.

**Theorem:** Let $M_d$ be a compact complex manifold with first Chern class $c_1 \in H^2(M_d; \mathbb{Z})$ divisible by $N$. Suppose an $S^1$-action on $M_d$ is given. Then the equivariant elliptic genus $\varphi_N(M_d, \lambda)$ does not depend on $\lambda \in S^1$. It equals the elliptic genus $\varphi_N(M_d, \lambda) = (M_d, 1)$. If the type $t$ of the action is $\neq 0 (N)$, then $\varphi_N(M_d) \equiv 0$.

**Proof:** Let $m$ be a natural number $\geq 1$ and $\lambda^\pm m = q^n$. Then $\lambda$ is of the form $\lambda = \lambda_0 q^{s/m}$ where $\lambda_0^m = 1$ and $s = \pm n$. We have

$$\varphi_N(M_d, \lambda_0 q^{s/m}) = \sum_X \varphi_N(X, \lambda_0 q^{s/m})$$

where the summation is over all the connected components of $M_d^P$. Since the elliptic function (34) has no poles for $\lambda_0$, the result follows. The vanishing $\varphi_N(M_d) = 0$ for $t \neq 0 (N)$ follows again from (25).

11. We want to point out some applications of the rigidity theorem.

If we develop in a cusp (1) with $k > 0$, we get a different version of the rigidity theorem (compare [19]). In particular, we get that $\chi(M_d, L^k, \lambda)$ does not depend on $\lambda$ for $k = 1, \ldots, N - 1$, in fact $\chi(M_d, L^k) = 0$, if the action is non-trivial. This is a well-known result ([12], [15]). For $N = 2$ and $k = 1$ it corresponds to the theorem in [5] on the $A$-genus.

The elliptic genus of level $N$ is strictly multiplicative in fibre bundles with a manifold $M_d$ with $c_1(M_d) \equiv 0 (N)$ as fibre and a compact connected Lie group $G$ of automorphisms of $M_d$ as structure group (compare [14] and [16]).

This we wish to apply, for example, to the compact irreducible Hermitian symmetric spaces $G/U$ studied in [7], §16. There we gave a formula for the coefficient $\chi(G/U)$ in

$$c_1(G/U) = \chi(G/U) \cdot g$$

where $g$ is a positive generator of the infinite cyclic group $H^2(G/U)$.

Take a system $w_1, \ldots, w_d$ of positive complementary roots for $G/U$ (see [7]). Here $d$ is the complex dimension of $G/U$. The roots $w_1, \ldots, w_d$ are linear forms in $x_1, \ldots, x_l$ where $l = \text{rk} U = \text{rk} G$, the $x_1, \ldots, x_l$ can be identified with a base of $H^1(T; \mathbb{Z})$ where $T$ is the maximal torus of $U$. Without proof we state the following result which is equivalent to the strict multiplicativity of the elliptic genus for $G/U$-bundles.

**Theorem:** Let $F(x) = f(x)^{-1}$ be the elliptic function introduced for level $N$ (see section 1). Let $w_1, \ldots, w_d$ be positive complementary roots for the irreducible Hermitian symmetric space $G/U$. Suppose $\lambda(G/U) \equiv 0 (N)$. Then

$$\sum_{\sigma \in W(G)W(U)} F(\sigma(w_1))F(\sigma(w_2)) \cdots F(\sigma(w_d)) = \varphi_N(G/U).$$ (35)
Here $W(G), W(U)$ are the Weyl groups. (An element $\sigma \in W(U)$ permutes $w_1, \ldots, w_d$. Therefore the sum over the $W(U)$-cosets is well-defined.)

The formula (35) is an identity in the $l$ variables $x_1, \ldots, x_l$. The sum is a constant, i.e. does not depend on these variables anymore.

The rigidity theorem in section 10 also gave a vanishing result. We give an example: Consider the Grassmannian

$$W(m, n) = U(m + n)/(U(m) \times U(n)).$$

We use the notation of [7]. As a system of positive roots of $U(m + n)$, we take

$$\{-x_i + x_j \mid 1 \leq i < j \leq m + n\}.$$

The complementary roots $w_r$ are given by $1 \leq i \leq m$ and $m + 1 \leq j \leq m + n$. Their sum equals

$$\sum_r w_r = -n \sum_{i=1}^{m} x_i + m \sum_{j=m+1}^{m+n} x_j = -(m + n) \sum_{i=1}^{m} x_i + m \sum_{j=1}^{m+n} x_j. \quad (36)$$

We put $-\sum_{i=1}^{m} x_i = g$ and $\sum_{j=1}^{m+n} x_j = \sigma_1$. Then $g$ becomes the positive generator of $H^2(W(m, n); \mathbb{Z})$ whereas $\sigma_1$ vanishes if regarded as element of this cohomology group. Therefore

$$\lambda(W(m, n)) = m + n.$$

We also see from (36) that $W(m, n)$ admits an $N$-balanced circle action of type $m$ if $m + n \equiv 0 \pmod{N}$. We obtain

**Proposition:** The elliptic genus $\varphi_N(W(m, n))$ vanishes if $m + n \equiv 0 \pmod{N}$ and $m \not\equiv 0 \pmod{N}$. For the complex projective spaces $P_n(\mathbb{C}) = W(n, 1)$ we have

$$\varphi_N(P_n(\mathbb{C})) = 0 \text{ if } n + 1 \equiv 0 \pmod{N}.$$

12. The elliptic function $f$ defined in section 1 satisfies a differential equation

$$\left( \frac{f'}{f} \right)^N + a_1 \left( \frac{f'}{f} \right)^{N-1} + \cdots + a_{N-1} \left( \frac{f'}{f} \right) + a_N = \frac{1}{f^N} + \alpha_{2N} f^N \quad (37)$$

with $\alpha_{2N} = e^{2\pi i N}$ (see section 1) where the $a_j$ are modular forms of weight $j$ for $\Gamma_1(N)$, (if $\alpha = 2\pi i / N$ in (1)). The polynomial

$$P(\xi) = \xi^N + a_1 \xi^{N-1} + \cdots + a_{N-1} \xi + a_N$$

has the following properties:

1) $a_{N-1} = 0$.
2) If $P' (\xi) = 0$, but $\xi \neq 0$, then $P(\xi)^2 = 4\alpha_{2N}$. 
The property 2) implies that the values at the critical points $\xi$ with $\xi \neq 0$ are all equal up to sign. In this case, the polynomial might be called almost-Chebyshev. Theodore J. Rivlin wrote to me that polynomials with essentially such properties occur in the literature under the name Zolotarev-polynomials. Also their relation to elliptic functions is known (see for example [10]). I plan to write a separate paper on these matters. For $N = 2$ the differential equation is of the form

$$f'' = 1 - a_2 f^2 + a_4 f^4.$$  

very well known for the elliptic genus of level 2 (see [14]).

Appendix IV: Zolotarev polynomials and the modular curve $X_1(N)$

by Rainer Jung, Max-Planck-Institut für Mathematik, Bonn

1 Zolotarev polynomials

In this appendix we want to study the relation between lattices $L$ in $\mathbb{C}$, together with a distinguished $N$-division point in $\mathbb{C}/L$, and Zolotarev polynomials $P(x)$ of degree $N$. These polynomials have the following nice property: If we denote the critical points of $P$ by $\xi_0, \ldots, \xi_{N-2}$, then the critical values of $P$ away from $\xi_0$ are all equal up to sign,

$$P(\xi_i) = \pm P(\xi_j) \quad \text{for } i \neq j \text{ and } 0 < i, j \leq N - 2.$$

We normalize $P$ to $P(x) = x^N + \cdots$ and to $\xi_0 = 0$ and restrict to the case where all $\xi_i$ are distinct. Then we get that $(P'(x)/x)^2$ divides $P(x)^2 - A^2$ with $A = \pm P(\xi_i)$. So there is a polynomial $Q(x) = x^4 + \cdots$ of degree 4, such that the following equation holds:

$$Q \cdot P'^2 = N^2 x^2 (P^2 - A^2).$$

This motivates the following

**Definition:** A polynomial $P(x) = x^N + \cdots$ is called a normalized Zolotarev polynomial (with critical value $\pm A$), if there exists a polynomial $Q(x) = x^4 + \cdots$ such that

$$Q \cdot P'^2 = N^2 x^2 (P^2 - A^2). \quad (1)$$

A Zolotarev polynomial $P$ is called degenerate if the discriminant $\text{discr}(Q)$ of $Q$ vanishes (i.e. if $Q$ has multiple zeroes).

**Remarks:**

1) For $N > 2$ the polynomial $P$ determines $A$ and $Q$ in (1) uniquely. Conversely $P$ and $A$ are uniquely determined by $Q$.

2) If $N = 2$, and $P$ is non-degenerate, then (1) reduces to $Q(x) = P(x)^2 - A^2$, so $Q$ resp. the pair $(P, A^2)$ uniquely determine each other.

3) If $N = 1$, equation (1) reduces to $Q(x) = x^2 (P(x)^2 - A^2)$, so $P$ is degenerate.
Examples for Zolotarev polynomials are the normalized Chebyshev polynomials $T_N(a)$ we already used in Chapter 7, section 7.5. They were defined by the property

$$T_N(a + a^{-1}) = a^N + a^{-N},$$

and are Zolotarev polynomials for $A = \pm 2$ and $Q(a) = a^2(a - 2)(a + 2)$. So we see that they are degenerate and furthermore that for the Chebyshev polynomials all the critical values coincide up to sign. All degenerate Zolotarev polynomials can be determined explicitly. By a straightforward calculation (cf. [Ju89]) one gets the

**Proposition:** If $P$ is a normalized degenerate Zolotarev polynomial of degree $N$, then either of the following two cases applies:

(i) $P(a) = (a - kA)(a + (N - k)A)^{N-k}$ with $A \in \mathbb{C}$, $k \in \mathbb{N}$, and $0 \leq k \leq N$. Equation (1) holds with $A = 0$ and $Q(a) = ((a - kA)(a + (N - k)A))^2$.

(ii) $P(a) = \mu^N T_N((a - \lambda \mu)/(a - \lambda + 2\mu))$, with $\lambda, \mu \in \mathbb{C}$, $\mu \neq 0$. Equation (1) holds with $A = \pm 2\mu^N$ and $Q(a) = a^2(a - (\lambda - 2\mu))(a - (\lambda + 2\mu))$.

Furthermore $P'(0) = 0$ if and only if $N > 1$ and in the first case $k \neq 0, N$ or $A = 0$ (i.e. $P(a) = a^N$), or in the second case $\frac{A}{\mu} = 2 \cos\left(\frac{\pi}{N}\right)$ for any $l$ with $0 < l < N$.

For the following we have to restrict our notion of Zolotarev polynomials:

**Definition:** A normalized Zolotarev polynomial $P$ of degree $N$ with critical value $\pm A$ is called admissible, if $P'(0) = 0$ and $P(a) \neq a^N$ for $N > 2$, resp. $P(a) \neq a^2$ or $A \neq 0$ for $N = 2$. For $N > 2$ we denote by $P_N$ (resp. $P_N^2$) the set of admissible normalized (non-degenerate) Zolotarev polynomials $P$ of degree $N$. For $N = 2$ we denote by $P_2$ (resp. $P_2^2$) the set of pairs $(P, C)$, such that $P$ is an admissible normalized (non-degenerate) Zolotarev polynomial of degree 2 with critical value $\pm A$, where $A^2 = 4C$. By $Q_N$ (resp. $Q_N^2$) we denote the set of normalized polynomials of degree 4, fulfilling (1) for some polynomial $P \in P_N$ (resp. $P \in P_N^2$) for $N > 2$, resp. for some pair $(P, C) \in P_2$ (resp. $(P, C) \in P_2^2$) for $N = 2$.

**Remark:** If $P$ is non-degenerate, then (1) ensures that $P'(0) = 0$ and $P \neq x^N$ for $N > 2$, resp. $(P, A) \neq (x^2, 0)$ for $N = 2$, so $P$ is admissible. Therefore admissability is only a restriction on the set of degenerate Zolotarev polynomials that we already listed above.

For the rest of this appendix we will always use the term Zolotarev polynomial synonymously for admissible Zolotarev polynomial.

From the remarks 1) and 2) above and the list of degenerate Zolotarev polynomials, we get the following

**Lemma:** The canonical map $\Omega_N : Q_N \rightarrow P_N$ mapping a polynomial $Q \in Q_N$ to the Zolotarev polynomial $P$ defined by (1) (resp. to the pair $(P, A^2/4)$ for $N = 2$) is a bijection. It also induces a bijection from $Q_N^2$ to $P_N^2$.

There is also a map connecting Zolotarev polynomials for different degree (we only give the description for $N > 2$, but the construction works analogously for $N = 2$): If $Q$
IV.2 Interpretation as an algebraic curve

is in $Q_N$ and $P = \Omega_N(Q) \in \mathcal{P}_N$ so that (1) holds for some critical value $A$, then we have $(A/2)^n T_n(P(x)/(A/2)) \in \mathcal{P}_{nN}$ and equation (1) holds for the same polynomial $Q$ and the critical value $2(A/2)^n$. So we have $Q_N \subset Q_{nN}$ and if we denote by $\iota_n$ the map

$$\iota_n: \mathcal{P}_N \to \mathcal{P}_{nN}$$

$$P(x) \mapsto (A/2)^n T_n(P(x)/(A/2))$$

we get the following commutative diagram:

$$\begin{array}{ccc}
\Omega_N & \subset & \Omega_{nN} \\
\downarrow & & \downarrow \\
\mathcal{P}_N & \xrightarrow{\iota_n} & \mathcal{P}_{nN}
\end{array}$$

Since the polynomial $Q$ does not change when applying the map $\iota_n$ to $P$, the diagram induces a similar one on non-degenerate polynomials. Furthermore, since $\Omega_N$ and $\Omega_{nN}$ are bijections, the map $\iota_n$ is injective and the diagram also gives $\iota_n \circ \iota_m = \iota_{nm}$.

2 Interpretation as an algebraic curve

There exists an action of $\mathbb{C}^*$ on the set of polynomials $F(x)$ of degree $r$, given by

$$\lambda(F(x)) = F(\lambda x)/\lambda^r \quad \text{for } \lambda \in \mathbb{C}^*.$$ 

If $P$ is a Zolotarev polynomial of degree $N$ for the critical value $A$, and $Q$ is the polynomial of degree $4$ in equation (1), then $\lambda(P)$ is again a Zolotarev polynomial for the critical value $\lambda^{-N} A$ and satisfies (1) with $\lambda(Q)$. So the action induces an action on $Q_N, Q_{2N}, \mathcal{P}_N$ and $\mathcal{P}_N$, where on $\mathcal{P}_2$ (resp. on $\mathcal{P}_N$) $\lambda$ acts as $\lambda(P, C) = (\lambda(P), \lambda^{-4} C)$. The action is compatible with the maps $\Omega_N$ and $\iota_n$. We denote the induced equivalence relation by "~".

We want to identify the polynomials with their coefficients. Later on we will be interested in equivalence classes of polynomials, so we make the

Definition: For $n_0, \ldots, n_r \in \mathbb{N}$, the weighted projective space $P^{n_0, \ldots, n_r}(\mathbb{C})$ is defined by $(\mathbb{C}^{r+1} \setminus \{0\})/\sim$, where $(z_0, \ldots, z_r) \sim (z_0', \ldots, z_r')$ if and only if there exists $\lambda \in \mathbb{C}$ such that $z_i = \lambda^{n_i} z_i'$ for all $i = 0, \ldots, r$. The equivalence class of a point $(z_0, \ldots, z_r) \in \mathbb{C}^{r+1}$ under $\sim$ will be denoted by $[z_0: \ldots: z_r]$.

As an example, choosing $n_i = 1$ for all $i$, leads to the usual complex projective space $P_r(\mathbb{C})$. Weighted projective spaces are normal, irreducible, projective algebraic varieties, but in general they are singular (cf. [Do82]).
Now we have the following embeddings:

\[ Q_N^\circ/\sim \subset Q_N/\sim \hookrightarrow \mathbb{P}^{1,2,3,4}(\mathbb{C}), \]

\[ Q(x) = x^4 + q_1 x^3 + q_2 x^2 + q_3 x + q_4 \mapsto (q_1 : q_2 : q_3 : q_4), \]

\[ P_N^\circ/\sim \subset P_N/\sim \hookrightarrow \mathbb{P}^{1,\ldots,N-2,N}(\mathbb{C}) \quad \text{for } N > 2, \]

\[ P(x) = x^N + a_1 x^{N-1} + \cdots + a_N \mapsto (a_1 : \ldots : a_{N-2} : a_N), \]

\[ P_N^H/\sim \subset P_2/\sim \hookrightarrow \mathbb{P}^{2,4}(\mathbb{C}), \]

\[ (P,C) \mapsto (a_2 : C), \]

where \( P(x) = x^2 + a_2 \) in the last map. For the Zolotarev polynomials we don't have to care about the coefficient \( a_{N-1} \), since we required them to be admissible, so \( P'(0) = 0 \), i.e. \( a_{N-1} = 0 \).

The images of these embeddings will be denoted by \( \mathcal{N}_N \) (resp. \( \mathcal{N}_N^\circ \)) for \( Q_N/\sim \) (resp. \( Q_N^\circ/\sim \)) and \( \mathcal{M}_N \) (resp. \( \mathcal{M}_N^\circ \)) for \( P_N/\sim \) (resp. \( P_N^\circ/\sim \)).

The sets \( \mathcal{N}_N \) and \( \mathcal{M}_N \) are algebraic curves in the respective weighted projective spaces. Their defining equations can be explicitly determined by a closer look at equation (1) (cf. [Ju89]):

For \( i \in \mathbb{Z} \) we inductively define polynomials \( A_i \in \mathbb{Q}[z_1, \ldots, z_4, N] \) by \( A_i = 0 \) for \( i < 0 \), \( A_0 = 1 \), and

\[ A_i = \frac{1}{2i(2N-i)} \sum_{k=1}^{4} (N+k-i)(2N+k-2i)z_k A_{i-k} \quad \text{for } i > 0. \]

As one easily sees, the \( A_i \) are homogeneous of weight \( i \) (for \( i > 0 \)) if one assigns the weights \( k \) to \( z_k \) and 0 to \( N \). Furthermore if \( Q(x) = x^4 + q_1 x^3 + \cdots + q_4 \in \mathcal{Q}_N \) then for \( P = \Omega_N(Q) = x^N + a_1 x^{N-1} + \cdots + a_N \in \mathcal{P}_N \) we have \( a_i = A_i(q_1, \ldots, q_4, N) \).

From this one easily derives (cf. [Ju89]):

**Proposition:** The set \( \mathcal{N}_N \subset \mathbb{P}^{1,2,3,4}(\mathbb{C}) \) is equal to the algebraic curve given by \( A_{N-1}(z_1, \ldots, z_4, N) = 0 \) and \( A_{N+1}(z_1, \ldots, z_4, N) = 0 \). Thus for a polynomial \( Q(x) = x^4 + q_1 x^3 + \cdots + q_4 \) there exists a Zolotarev polynomial \( P(x) \) of degree \( N \) satisfying (1), if and only if \( A_{N-1}(q_1, \ldots, q_4, N) = 0 \) and \( A_{N+1}(q_1, \ldots, q_4, N) = 0 \).

**Examples:** For the first few polynomials \( A_i \) we get:

\[ A_1 = \frac{N}{2} q_1, \]

\[ A_2 = \frac{N}{16} \left( (2N-3)q_1^2 + 4q_2 \right), \]

\[ A_3 = \frac{N}{96} \left( (2N-5)(N-2)q_3^3 + 12(N-2)q_1 q_2 + 16q_3 \right), \]

\[ A_4 = \frac{N}{1536} \left( (2N-7)(2N-5)(N-3)q_4^4 + 24(2N-5)(N-3)q_1^2 q_2 + 32(4N-9)q_1 q_3 + 48(N-3)q_2^2 + 192q_4 \right). \]
The algebraic curves $\mathcal{N}_2$ to $\mathcal{N}_5$ are given by:

$\mathcal{N}_2 = \{(q_1 : \ldots : q_4) \in P^{1,2,3,4}(C) \mid q_1 = 0, q_3 = 0\} \cong P^{2,4}(C) \cong P^{1,2}(C) \cong P_1(C)$,

$\mathcal{N}_3 = \{(q_1 : \ldots : q_4) \in P^{1,2,3,4}(C) \mid q_2 = -\frac{3}{4} q_1^2, q_4 = -\frac{1}{2} q_1 q_3\} \cong P^{1,3}(C) \cong P_1(C)$,

$\mathcal{N}_4 = \{(q_1 : \ldots : q_4) \in P^{1,2,3,4}(C) \mid q_3 = -\frac{3}{8} q_1 (q_1^2 + 4 q_2),
\frac{5q_1^2 q_3 + 24 q_1 q_4 + 4 q_2 q_3 = 0}\}
\cong \{(q_1 : q_2 : q_4) \in P^{1,2,4}(C) \mid q_1 ((q_1^2 + 4 q_2)(5q_1^2 + 4 q_2) - 64 q_4) = 0\}
\cong P^{2,4}(C) \cup P^{1,2}(C) \cong P_1(C) \cup P_1(C),$

where the two components intersect in the point $(0 : 2 : 0 : 1)$, and

$\mathcal{N}_5 = \{(q_1 : \ldots : q_4) \in P^{1,2,3,4}(C) \mid q_4 = -\frac{1}{96} (176 q_3 q_4 + 48 q_2^2 + 120 q_2 q_1^2 + 15 q_1^4),
\frac{6 q_4 (12 q_2 + 21 q_1^2) + 16 q_3^2 + 36 q_3 q_2 q_1 + 15 q_3 q_1^2 = 0}\}
\cong \{(q_1 : q_2 : q_3) \in P^{1,2,3}(C) \mid q_1 (q_1^6 + 2700 q_4 q_2 + 3456 q_3^2 q_3 + 2448 q_4^2 q_2^2
+ 1536 q_1 q_2 q_3 + 576 q_2^2 - 256 q_3^2 = 0)\}.$

Analogously one can find the equations for the coefficients of the curve $\mathcal{M}_N$ of Zolotarev polynomials (cf. [Ju89]).

**Examples:** The set of Zolotarev polynomials in degrees two to five is given by

$\mathcal{M}_2 = \{(a_2 : C) \in P^{2,4}(C)\} = P^{2,4}(C),$

$\mathcal{M}_3 = \{(a_1 : a_3) \in P^{1,3}(C)\} = P^{1,3}(C),$

$\mathcal{M}_4 = \{(a_1 : a_2 : a_4) \in P^{1,2,4}(C) \mid a_1 (128 a_2^2 - 144 a_2 a_1^2 + 27 a_1^4 - 512 a_4) = 0\},$

$\mathcal{M}_5 = \{(a_1 : a_2 : a_3 : a_5) \in P^{1,2,3,5}(C) \mid
a_5 = \frac{1}{3125} (875 a_3 a_2 - 950 a_3 a_1^2 - 725 a_2^2 a_1 + 700 a_2 a_1^2 - 128 a_1^4),
25 a_2^2 - 70 a_3 a_2 a_1 + 4 a_3 a_1^3 - 20 a_2^2 + 37 a_2 a_1^2 - 8 a_2 a_1^4 = 0\}.$

For $N > 5$ there are $N - 5$ equations that express $a_5$ to $a_{N-2}$ and $a_N$ as polynomials in $a_1$ to $a_4$. The remaining two equations involve only the variables $a_1$ up to $a_4$ and are homogeneous of degree $N - 1$ and $N + 1$.

The curves $\mathcal{N}_N$ and $\mathcal{M}_N$ are in general (i.e. for $N$ not prime) not irreducible. In fact we already saw, that $\mathcal{N}_d$ is contained in $\mathcal{N}_N$ for each divisor $d$ of $N$, and that $\mathcal{M}_d$ is embedded in $\mathcal{M}_N$. We will see later, that the curves have exactly one component for each divisor $d$ of $N$ and that the components only intersect in degenerate Zolotarev polynomials.
3 The differential equation — revisited

In this section we want to recall the basic constructions of Chapter 7 and Appendix I, §7, to derive a close connection between pairs \((L, z_0)\), where \(L \subset \mathbb{C}\) is a lattice and \(z_0 \in \mathbb{C}/L\) is an \(N\)-division point, and Zolotarev polynomials.

We will often use such pairs \((L, z_0)\) as above, so we define

\[ \mathcal{L} := \{(L, z_0) \mid L \subset \mathbb{C} \text{ a lattice}, z_0 \in \mathbb{C}/L, z_0 \neq 0\}, \]

\[ \mathcal{L}_N := \{(L, z_0) \in \mathcal{L}, N \cdot z_0 = 0\}. \]

For \((L, z_0) \in \mathcal{L}_N\) there exists a well-defined function \(h = h_{L, z_0, N}\) with the following properties (cf. Chapter 7 and Appendix I, §6):

1) \(h\) is elliptic for the lattice \(L\),
2) the divisor of \(h\) is \((h) = N \cdot (0) - N \cdot (z_0)\),
3) \(h\) is normalized by \(h(z) = z^N + O(z^{N+1})\).

The function \(h\) depends on \(N\), not only on \((L, z_0)\), since we did not demand \(N\) to be the exact order of \(z_0\). But one easily shows that \(h_{L, z_0, nN} = (h_{L, z_0, N})^n\). In the following we will also make use of the function \(g = g_{L, z_0} := \frac{1}{N} h_{L, z_0, N}/h_{L, z_0, N}\) (which does not depend on \(N\) by the above). This function has the properties

1) \(g\) is elliptic for the lattice \(L\),
2) its poles are in \(0\) and in \(z_0\), both of order one with residues 1 and \(-1\) resp.

In Chapter 7 we also introduced the involution

\[ \tau : z \mapsto z_0 - z \]

and we saw that \(g\) is invariant under \(\tau\): \(g \circ \tau = g\). Furthermore any function \(u\) on \(\mathbb{C}/L\) and invariant under \(\tau\) is a rational function in \(g\) and in fact a polynomial in \(g\) if \(u\) has only poles in \(0\) and \(z_0\). In Chapter 7, section 7.2, this was used to get the two differential equations

\[ P(g) = Ch + \frac{1}{h}, \]

and

\[ Q(g) = g^2, \]

where \(P(x) = P_{L, z_0, N} = x^N + \cdots\) and \(Q(x) = Q_{L, z_0}(x) = x^4 + \cdots\) are normalized polynomials of degree \(N\) resp. \(4\) and \(C\) is a constant depending on \(L\), \(z_0\), and \(N\). The two polynomials were related by the equation

\[ Q \cdot P^2 = N^2 x^2 (P^2 - 4C), \]
so \( P \) is a normalized Zolotarev polynomial. The discriminant of the polynomial \( Q \) does not vanish (i.e. \( Q \) has only simple zeroes): From the differential equation for \( g \) we see that \( Q(x) \) vanishes for \( x = g(z) \) where \( g'(z) = 0 \). Since \( g \) has two poles of order one it takes each value exactly twice (counted with multiplicities) and its derivative takes each value four times. Now \( g \) is invariant under \( \tau \), so its derivative \( g' \) vanishes exactly at the four distinct points \( z_1, \ldots, z_4 \) characterized by \( \tau(z_i) = z_i \). But the four values \( g(z_i) \) have to be distinct, since \( g \) takes them at least with order two (\( g'(z_i) = 0 \)). Thus \( Q \) has only simple zeroes.

Therefore the Zolotarev polynomial \( P \) is non-degenerate, and the differential equations for the elliptic functions \( h \) and \( g \) finally give us maps

\[
\Psi_N : \mathcal{L}_N \rightarrow \mathcal{P}_N^0 \\
(L, z_0) \mapsto \begin{cases} 
\mathcal{P}_{L,z_0,N}, & \text{for } N \neq 2, \\
\mathcal{P}_{L,z_0,2,C}, & \text{for } N = 2,
\end{cases}
\]

and

\[
\Phi_N : \mathcal{L}_N \rightarrow \mathcal{Q}_N^0 \\
(L, z_0) \mapsto Q_{L,z_0}.
\]

Since \( P_{L,z_0,N} \) is a Zolotarev polynomial satisfying (1) with \( Q_{L,z_0} \), we obviously have \( \Psi_N = \Omega_N \circ \Phi_N \).

If \( z_0 \) is an \( N \)-division point of \( \mathbb{C}/L \), then we can also take it as an \( nN \)-division point, i.e. \( \mathcal{L}_N \subseteq \mathcal{L}_{nN} \). The function \( g \) does not depend on \( N \) as well as the polynomial \( Q \), so we have

\[
P_{L,z_0,nN}(x) = \iota_n(P_{L,z_0,N}(x))
\]

and

\[
C_{L,z_0,nN} = C_{L,z_0,N}^n,
\]

where \( \iota_n \) is the injection from the first section.

Now we can extend the commutative diagram of section 1 to:

\[
\begin{array}{ccccccc}
\Psi_N & \downarrow & \Psi_N & \downarrow & \Psi_N & \downarrow & \Psi_N \\
\mathcal{L}_N & \subset & \mathcal{L}_{nN} & \subset & \mathcal{Q}_{nN} & \subset & \mathcal{Q}_{nN} \\
\Omega_N & \downarrow & \Omega_{nN} & \downarrow & \Omega_{nN} & \downarrow & \Omega_{nN} \\
\mathcal{P}_N & \leadsto & \mathcal{P}_{nN} & \leadsto & \mathcal{P}_{nN} & \leadsto & \mathcal{P}_{nN}
\end{array}
\]
4 Modular interpretation of Zolotarev polynomials

In the last section we saw that we can associate a non-degenerate Zolotarev polynomial $P_{L,z_0,N} = \Psi_{N}(L,z_0)$ to each pair $(L,z_0) \in \mathcal{L}_N$. Now we want to prove the

**Theorem:** The maps $\Phi_N$ and $\Psi_N$ are bijections.

**Proof:** Since $\Psi_N = \Omega_N \circ \Phi_N$ and $\Omega_N$ is a bijection, it suffices to prove bijectivity for the map $\Phi_N$. For this we need the following

**Proposition:** Let $Q(x) = x^4 + q_1 x^3 + q_2 x^2 + q_3 x + q_4$ be a normalized polynomial of degree 4, such that $\text{discr}(Q) \neq 0$. Then there exists a unique meromorphic function $g(z)$ with $g(z) = \frac{1}{z} + O(1)$ and $Q(g) = g^2$. This function is elliptic for a lattice $L \subset \mathbb{C}$ and with $\bar{Q}(z) = Q(z - q_1/4) = x^4 + \bar{q}_2 x^2 + \bar{q}_3 x + \bar{q}_4$ we have

$$g(z) = - \frac{1}{2} \cdot \frac{\varphi'(z) + \varphi'(z_0)}{\varphi(z) - \varphi(z_0)} - \frac{q_1}{4}$$

where $\varphi$ is the Weierstrass $\wp$-function for the lattice $L$ with lattice constants $p_2(L) = \bar{q}_4 + \bar{q}_3^2/12$ and $p_3(L) = \bar{q}_4 q_2/6 - \bar{q}_3^2/16 - \bar{q}_3^2/216$ and $z_0$ is the point on $\mathbb{C}/L$ that is different from zero. Therefore $(L,z_0)$ is uniquely determined by $Q_L, z_0 = \Phi_N(L,z_0)$, i.e. $\Phi_N$ is injective.

To prove the surjectivity of $\Phi_N$ we again use the proposition: Let $Q \in \mathcal{Q}_{N}$, so especially $\text{discr}(Q) \neq 0$. Let $g(z)$ be the function in the proposition, i.e. $g^2 = Q(g)$ and $g$ is elliptic for some lattice $L$. From the explicit formula for $g$ in the proposition we see that $g$ has only two poles, namely one in 0 and one in $z_0$, both of order one with residues 1 resp. -1. Now we have to show that $z_0$ is an $N$-division point of $\mathbb{C}/L$ and that $g = g_L, z_0$.

Since $Q \in \mathcal{Q}_{N}$ we know that $P := \Omega_N(Q)$ (resp. $(P,C) = \Omega_2(Q)$ for $N = 2$) is a normalized Zolotarev polynomial with $QP'' = N^2 x^2 (P^2 - A^2)$ (and $A^2 = 4C$ for $N = 2$). Denote by $f_1$ and $f_2$ the functions $f_1 := P'(g)$ and $f_2 := \frac{1}{N} f_1'/g = \frac{1}{N} P'(g) g'/g$ and by $h$ the function $h := \frac{A}{2} (f_1 + f_2)$. All of them are elliptic for $L$.
IV.5 The embedding of the modular curve

since $g$ is. From (1) and the definitions we have

$$f_2^2 = \left( \frac{1}{Ng} P'(g)g \right)^2 = \left( \frac{1}{Ng} P'(g) \right)^2 Q(g) =$$

$$= P(g)^2 - A^2 = f_1^2 - A^2$$

$$\Rightarrow 2f_2f'_2 = 2f_1f'_1$$

$$\Rightarrow f'_2 = \frac{f_1}{f_2} f_1 = N g f_1.$$

For the logarithmic derivative of $h$ we get

$$\frac{h'}{h} = \frac{f'_1 + f'_2}{f_1 + f_2} = \frac{f'_1 + N g f_1}{f_1 + \frac{1}{Ng} f'_1} = N g. \tag{2}$$

Since the only poles of $g$ are in $0$ and $z_0$ of order one and with residues $1$ resp. $-1$ we get from (2) for the divisor $(h)$ of $h$:

$$(h) = N \cdot (0) - N \cdot (z_0)$$

$$\Rightarrow N \cdot 0 - N \cdot z_0 = 0 \in C/L$$

$$\Rightarrow N \cdot z_0 = 0 \in C/L.$$ 

Therefore $z_0$ is an $N$-division point of $C/L$. Since $h$ has the same divisor as $h_{L,z_0,N}$ and

$$h = \frac{A^2}{2(f_1 + f_2)} = \frac{A^2(f_1 - f_2)}{2(f_1^2 - f_2^2)} =$$

$$= \frac{1}{2} (f_1 - f_2) = \frac{1}{zN} + O\left(\frac{1}{zN-1}\right)$$

satisfies the normalization condition, we have $h = h_{L,z_0,N}$ and (2) shows that $g = g_{L,z_0}$. Since $Q(g) = g^2$ we finally get $Q = Q_{L,z_0} = \Phi_N(L,z_0)$, so $\Phi_N$ is surjective. \(\square\)

In the next section degenerate Zolotarev polynomials will show up as values of $\Psi_N$ on degenerate lattices.

5 The embedding of the modular curve

In Appendix I, §7, we already saw that two pairs $(L, z_0)$ and $(L', z_0')$ in $L_N$ are isomorphic $(L, z_0) \sim (L', z_0')$, if and only if $(L', z_0') = \lambda (L, z_0)$ for some $\lambda \in \mathbb{C}^*$, where the action of $\mathbb{C}^*$ on $L_N$ is given by $\lambda (L, z_0) = (\lambda L, \lambda z_0)$. As one can easily verify using the axiomatic definition of the function $h_{L,z_0}$, we have

$$h_{\lambda L, \lambda z_0, N}(z) = \lambda^N h_{L,z_0,N}(z/\lambda)$$
and so
\[ g_{\Lambda L, \lambda x_0}(z) = g_{L, x_0}(z/\lambda)/\lambda. \]

Therefore \( Q_{\Lambda L, \lambda x_0} = \lambda(Q_{L, x_0}) \) and \( P_{\Lambda L, \lambda x_0, N} = \lambda(P_{L, x_0, N}) \), and the maps \( \Phi_N \) and \( \Psi_N \) are equivariant with respect to the \( \mathbb{C}^* \)-actions on \( L_N \) and \( Q_N \) resp. \( P_N \) (cf. section 2). Since they were bijections, they induce bijections on the set of equivalence classes:

\[
\begin{align*}
\Phi_N : Q_N / \sim & \cong N_N^0 \subset P^{1,2,3,4}(\mathbb{C}) \\
\Psi_N : P_N / \sim & \cong M_N^0 \subset P^{1,2,3,4}(\mathbb{C})
\end{align*}
\]

If we define \( L_{N,P} = \{(L, x_0) \in L_N \mid x_0 \text{ has exact order } N \text{ in } \mathbb{C}/L\} \) then the set \( L_N \) can be naturally written as the disjoint union \( L_N = \bigcup_{d|N} L_{d,P} \). This splitting is respected by the \( \mathbb{C}^* \)-action on \( L_N \). Furthermore for any divisor \( d \) of \( N \) we define \( Q_{d,P} := \Phi_N(L_{d,P}) = \Phi_d(L_{d,P}) \) and \( P_{d,N,P} := \Psi_N(L_{d,P}) = \psi_N/d(P_{d,P}) \). Then we have \( Q_{d,P} = \bigcup_{d|N} Q_{d,P} \) and \( P_{N,P} = \bigcup_{d|N} P_{d,N,P} \). Finally let \( N_{d,P} \subset N_N^0 \) (resp. \( M_{d,N,P} \subset M_N^0 \)) be the images of \( Q_{d,P} \) (resp. \( P_{d,N,P} \)) under the embeddings into weighted projective spaces we discussed in section 2.

From Appendix I, §7.1, we know that the set of equivalence classes \( L_{d,P} / \sim \) can be parametrized by \( \Gamma_1(d) \mathfrak{H} \) via \( \tau \mapsto (2\pi i(\mathbb{Z}\tau + \mathbb{Z}), 2\pi i/d) \). Restricting the above diagram to primitive \( d \)-division points, we have

\[
\begin{align*}
\Phi_N : N_{d,P}^0 & \subset L_{d,P} / \sim \\
\Psi_N : M_{d,N,P}^0 & \subset P^{1,2,3,4}(\mathbb{C})
\end{align*}
\]

Thus we get two embeddings of \( \Gamma_1(d) \mathfrak{H} \) into weighted projective spaces with images given by \( N_{d,P}^0 \) and \( M_{d,N,P}^0 \). From Appendix I, §7.1, we know, that in the homogeneous coordinates of the weighted projective spaces the embeddings are given by modular forms. To extend the maps to the whole of \( \Gamma_1(d) \mathfrak{H} \) (i.e. the union of \( \Gamma_1(d) \mathfrak{H} \) and the cusps) we have to know their values on the cusps of \( \Gamma_1(d) \). From Chapter 7, section 7.6 we know that the values of \( \Phi_N \) on the cusps of \( \Gamma_1(d) \) are given by

\[
\begin{align*}
(i) & \quad Q(x) = (x - k/d)(x + (d - k)/d) \text{ for } 0 < k < d, \\
(ii) & \quad Q(x) = x^2(x^2 + 2 \zeta \zeta^t + 2x + 1) \text{ for } \zeta = \zeta \zeta^{1/2} \text{ and } \gcd(l, d) = 1.
\end{align*}
\]
Thus the values of $\Phi_N$ on the cusps are polynomials $Q$ that correspond to degenerate Zolotarev polynomials of degree $N$ and we can combine the maps in (3), extended to the compactified modular curve $\Gamma_1(d)\backslash \mathcal{H}$, to get

$$\Phi_N: \mathcal{N}_N \subset P^{1,2,3,4}(\mathbb{C})$$

$$\bigcup_{d|N} \Gamma_1(d)\backslash \mathcal{H}$$

$$\Phi_N: \mathcal{M}_N \subset P^{1,\ldots,N-2,N}(\mathbb{C})$$

The maps $\Phi_N$ and $\Psi_N$ are surjective and away from the cusps they are also injective. The degenerate Zolotarev polynomials of type (ii) have only one preimage, the ones of type (i) have $\varphi(\gcd(k,d))$ preimages on the component $\Gamma_1(d)\backslash \mathcal{H}$, where $\varphi$ is the Euler $\varphi$-function. Therefore the maps are embeddings away from the cusps and are also embeddings for components $\Gamma_1(d)\backslash \mathcal{H}$ with $d$ a prime number. Furthermore, the images of the different components only intersect in degenerate Zolotarev polynomials of type (i).

### 6 Applications to elliptic genera

The image of a genus on the rational cobordism ring is equal to the $\mathbb{Q}$-algebra $A$ generated by the coefficients of the characteristic power series $x/f(x)$, which in turn is equal to the $\mathbb{Q}$-algebra generated by the coefficients of the power series $f'/f$. In the case of elliptic genera of level $N$ we have $f'/f = g$, where $g$ satisfies a differential equation $g^2 = Q(g)$ with $Q \in \mathbb{Q}_N$. So for $Q(x) = x^4 + q_1x^3 + q_2x^2 + q_3x + q_4$ we have $A = [q_1, \ldots, q_4]$. Since $Q(x) \in \mathbb{Q}_N$, the coefficients of the polynomial satisfy the two relations $A_{N-1}(q_1, \ldots, q_4) = 0$ and $A_{N+1}(q_1, \ldots, q_4) = 0$, we described in section 2 of this appendix.

For the universal elliptic genus of level $N$ we also know that $q_1$ up to $q_4$ are modular forms on $\Gamma_1(N)$, so we get

**Proposition:** The rational image $A$ of the universal elliptic genus of level $N$ is generated by 4 modular forms $q_1, \ldots, q_4$, of weight 1 up to 4, which satisfy 2 weighted homogeneous relations $A_{N-1}(q_1, \ldots, q_4) = 0$ and $A_{N+1}(q_1, \ldots, q_4) = 0$, of degree $N-1$ and $N+1$.

For general $N$ there will be more relations, since the algebraic curve with function field $\mathbb{Q}[q_1, \ldots, q_4]/(A_{N-1}, A_{N+1})$ has one component for each divisor $d$ of $N$, the component parametrized by modular forms on $\Gamma_1(N)$ is the one with $d = N$. For $N$ prime, we have only one component and there are no more relations.

That means for large $N$ the image of the genus will only be a small subring of the ring of modular forms on $\Gamma_1(N)$. 
In his Diplomarbeit [Hö91], G. Höhn studies a universal elliptic genus $\varphi_{\text{all}}$ that generalizes elliptic genera of all levels:

This genus belongs to the characteristic power series $x/f(x)$ such that $g = f'/f$ satisfies $g^2 = Q(g)$ for $Q(x) = x^4 + q_1 x^3 + q_2 x^2 + q_3 x + q_4$ and $q_1, \ldots, q_4$, indeterminates, i.e. the polynomial $Q$ is no longer restricted to belong to a Zolotarev polynomial. Elliptic genera of any level $N$ factorize over this genus $\varphi_{\text{all}}$. After a homogeneous change of coordinates Höhn gets

$$\varphi_{\text{all}} : \Omega \otimes \mathbb{Q} \to \mathbb{Q}[A, B, C, D],$$

where $A, B, C, D$ are again indeterminates of weights 1 up to 4 (i.e. $q_1$ up to $q_4$ can be expressed as homogeneous polynomials in $A, B, C, D$ and vice versa), and for an SU manifold $M$, i.e. a stably almost complex manifold $M$ with $c_4(M) = 0$, there holds $\varphi_{\text{all}}(M) \in \mathbb{Q}[B, C, D].$

Using the rigidity theorem of Hirzebruch for level $N$ genera (see Appendix III), Höhn shows the following

**Theorem:** The universal elliptic genus $\varphi_{\text{all}}$ is rigid for $S^1$-actions on SU manifolds. 

Another result he proves is the invariance of level $N$ elliptic genera under blow ups in codimension 1 modulo $N$. Furthermore Höhn determines the kernels of $\varphi_{\text{all}}$ and of the level $N$ elliptic genera in terms of ideals of manifolds with certain kinds of $S^1$-actions and ideals generated by certain fibre bundles.

*A publication of the Max-Planck-Institut für Mathematik, Bonn
The texts of this series are intended for graduate students and all mathematicians who wish to broaden their research horizons or who simply want to get a better idea of what is going on in a given field. They are introductions to areas close to modern research and prepare the reader for a better understanding of research papers. Many of them can be used to supplement graduate courses. The series comprises two subseries, one in English, the other in German.

F. Hirzebruch, Th. Berger, and R. Jung

**Manifolds and Modular Forms**

This book provides a comprehensive introduction to the theory of elliptic genera due to Ochanine, Landweber, Stong, and others. The theory describes a new cobordism invariant for manifolds in terms of modular forms.

The book evolved from notes of a course given at the University of Bonn. After providing some background material elliptic genera are constructed, including the classical genera signature and the index of the Dirac operator as special cases. Various properties of elliptic genera are discussed, especially their behaviour in fibre bundles and rigidity for group actions. For stably almost complex manifolds the theory is extended to elliptic genera of higher level.

The text is in most parts self-contained. The results are illustrated by explicit examples and by comparison with well-known theorems. The relevant aspects of the theory of modular forms are derived in a separate appendix, providing also a useful reference for mathematicians working in this field.
