ON THE ALGEBRAIC K-THEORY OF FORMAL POWER SERIES

AYELET LINDENSTRAUSS AND RANDY MCCARTHY

Abstract. For \( R \) a discrete ring, and \( M \) a simplicial \( R \)-bimodule, we let \( T_R(M) \) denote the (derived) tensor algebra of \( M \) over \( R \), and \( T_R^\pi(M) \) denote the ring of formal (derived) power series in \( M \) over \( R \). We define a natural transformation of simplicial \( R \)-bimodules \( \Phi : \Sigma \tilde{K}(R; -) \to \tilde{K}(T_R^\pi( -)) \) which is closely related to Waldhausen’s equivalence \( \tilde{K}(\text{Nil}(R; -)) \cong \tilde{K}(T_R^\pi( -)) \). We show that \( \Phi \) induces an equivalence on any finite stage of the Goodwillie Taylor towers of the functors at any simplicial bimodule. This is used to show that there is an equivalence of functors \( \Sigma \tilde{W}(R; -) \cong \text{holim}_n \tilde{K}(T_R^\pi( -) / I^{n+1}) \), where \( W(R; -) \) is what the Goodwillie Taylor tower of \( \tilde{K}(R; -) \) converges to, and for connected bimodules, also an equivalence \( \tilde{K}(R; -) \cong \tilde{K}(T_R( -)) \).

Read in the opposite direction, the equivalence on the Taylor towers gives us the values that the finite stages of the Goodwillie Taylor towers of the functor of augmented \( R \)-algebras \( A \mapsto \tilde{K}(A) \) take on augmented algebras which are of the form \( T_R(M) \) for a connected \( R \)-bimodule \( M \).

1. Introduction

Throughout this paper, let \( R \) be a unital ring, and let \( M \) be a simplicial \( R \)-bimodule. We will relate the algebraic K-theory of parametrized endomorphisms (the K theory of the category whose objects are pairs \((P, f)\) with \( P \) a f.g. projective right \( R \)-module and \( f : P \to P \otimes_R M \) a map of right \( R \) modules, with maps being maps of the modules \( P \) which induce commutative diagrams) with the algebra \( T_R^\pi(M) \) of formal (derived) power series in \( M \) over \( R \) (and in the case of connected bimodules, with the algebraic K-theory of the (derived) tensor algebra \( T_R(M) \) which is weakly equivalent to it).

The idea for the map we use to relate them came from Waldhausen [W1], where he defines an equivalence

\[
\Sigma \tilde{K}(\text{Nil}(R; -)) \cong \tilde{K}(T_R( -))
\]

One can model his \( \tilde{K}(\text{Nil}(R; M)) \) (see also [B]) as the algebraic K-theory of the full subcategory of the category we used to define \( K(R; M) \) which consists of modules \( P \) and maps \( m : P \to P \otimes_R M \) which are nilpotent, that is, for every \( p \in P \) some power \( m^\otimes_R i \) vanishes on \( p \) (see equation (3.2) below for the meaning of \( m^\otimes_R i \)). In these terms, for a nilpotent map \( m : P \to P \otimes_R M \), Waldhausen’s equivalence sends

\[
m \mapsto (1 - m)^{-1} = \sum_{i=0}^\infty m^\otimes_R i
\]
where the latter is extended $\mathcal{T}_R(M)$-linearly to be viewed as a map from $P \otimes R \mathcal{T}_R(M)$ to itself, and the infinite sum makes sense because at every point in the domain of the map, the infinite sum is in fact finite. This suggests that it would be interesting to look at this map $m \mapsto (1 - m)^{-1}$ defined on the full $\mathcal{K}(R; M)$. Of course, the map would not be able to land in $\mathcal{K}(\mathcal{T}_R(M))$ anymore because of the problem of the convergence of the infinite sum, but would land in some sort of (non-commutative, unless $R$ is commutative and $M$ is symmetric with a single generator) localization of it which inverts elements of the form $1 - m$ in $P \otimes R \mathcal{T}_R(M)$ to itself, and the idea would be that one would get a diagram

$$
\begin{align*}
\Sigma \mathcal{K}(\text{Nil}(R; M)) & \xrightarrow{\text{Waldhausen}} \Sigma \mathcal{K}(\mathcal{T}_R(M)) \\
\mathcal{K}(R; M) & \xrightarrow{\text{Appropriate localization of } \mathcal{K}(\mathcal{T}_R(M))}
\end{align*}
$$

with the horizontal maps being weak equivalences.

Betley [B] began this program by showing that when $R$ is a field and $M$ a discrete $R$-bimodule, the invariant we call $\mathcal{K}(R; M)$ is a localization in the sense of Neeman and Ranicki [NR] of $\mathcal{K}(\mathcal{T}_R(M))$, coming from inverting maps of the form $1 - m$ in the category of finitely generated projective $\mathcal{T}_R(M)$ modules.

We will instead extend Waldhausen’s map by looking at formal power series rather than at the tensor algebras. Thus for any unital ring $R$, we define a natural transformation of simplicial $R$-bimodules

$$
\Phi : \Sigma \mathcal{K}(R; M) \to \mathcal{K}(\mathcal{T}_R(M))
$$

and study its behavior on the Taylor towers in the sense of Goodwillie. The Goodwillie Taylor tower of the parametrized endomorphisms $\Sigma \mathcal{K}(R; M)$ can be described (see [LMcC1]) as follows: we look at circular derived tensor products of $i$ copies of $M$,

$$
\begin{align*}
\mathcal{T}_R(M) & \otimes R \mathcal{T}_R(M) \\
& \vdots \\
& \mathcal{T}_R(M) \otimes R M \otimes R M
\end{align*}
$$

where the cyclic group $C_i$ acts by rotation. The $n$’th stage of the Goodwillie Taylor tower of $\Sigma \mathcal{K}(R; M)$ is the homotopy inverse limit, taken over $i \leq n$, of all the $C_i$ fixedpoints in the circular derived tensor product of $i$ copies of $M$. When $M = R$, this invariant was introduced in [BHM] and called $\mathcal{T}_R(R)$.

We obtain in Theorem [3.1] below that $\Phi$ induces equivalences

$$
(1.1) \quad \Phi_n : \Sigma W_n(R; M) \xrightarrow{\simeq} P_n \mathcal{K}(\mathcal{T}_R(M))
$$

for every $n$. When $M$ is a connected simplicial bimodule, both of these Goodwillie Taylor towers converge, resulting in Corollary [3.3] for connected $M$

$$
\Phi : \Sigma \mathcal{K}(R; M) \xrightarrow{\simeq} \mathcal{K}(\mathcal{T}_R(M)).
$$
This is in keeping with the philosophy of extending Waldhausen’s map, as explained above, since when $M$ is connected the infinite sum $\sum_{i=0}^{\infty} m^i$ ‘homotopy converges’.

For a general bimodule $M$, by comparing $\tilde{K}(\mathcal{T}_R(I))$ to the more tractable functors $\tilde{K}(\mathcal{T}_R(I)/I^{n+1})$, we obtain as Corollary 3.2 the formula

$$\Sigma W(R; M) \xrightarrow{\cong} \text{holim}_n \tilde{K}(\mathcal{T}_R(M)/I^{n+1}).$$

Another motivation for the result of Corollary 3.3 comes from [CCGH], where Carlsson et al. show in Theorem 3 that for a simplicial space $X$,

$$A(\Sigma X) \simeq \Sigma \bigvee_n [(\mathcal{S}X)^\wedge n]_{hC_n}.$$

But by James Milnor splitting, for $X$ connected $A(\Sigma X) = K(\Sigma^\infty(\Omega \Sigma X)) \simeq K(T_\mathcal{S}X)$, while Tom-dieck splitting (as in [BHM] for the case $R = M$, and more generally as in [I]) gives $\Sigma W(\mathcal{S}, \mathcal{S}X) \simeq \Sigma \bigvee_n [(\mathcal{S}X)^\wedge n]_{hC_n}$. In these terms, then, the [CCGH] result could be written for connected $X$ as

$$\Sigma W(\mathcal{S}, \mathcal{S}X) \simeq K(T_\mathcal{S}X),$$

which is an FSP version (which we do not prove) of our result of Corollary 3.3 for $R = \mathbb{S}$ and $M = \mathcal{S}X$.

Read in the opposite direction, if we are interested in understanding the K-theory of augmented simplicial $R$-algebras rather than the K-theory of endomorphisms, the equation (1.1) proved in Theorem 3.1 (applied to connected $M$ where $\mathcal{T}_R(M) \simeq T_\mathcal{S}X$) tells us the finite stages of the Goodwillie Taylor tower of the functor $M \mapsto \tilde{K}(T_R(M))$ on simplicial $R$-bimodules (since the stages of the Goodwillie Taylor are determined by their values on connected spaces).

It would be very interesting to know the Goodwillie Taylor tower of the functor $A \mapsto \tilde{K}(A)$ on the category of augmented simplicial $R$-algebras. While that cannot be deduced from our result, it is interesting to note that the Goodwillie Taylor tower of a functor $F$ from augmented simplicial $R$-algebras to spectra, when applied to algebras of the form $T_\mathcal{S}X$, coincides with the Goodwillie Taylor tower of the functor $F(T_R(\_))$ from simplicial $R$-bimodules to spectra. This is because the functor $M \mapsto T_R(M)$ from $R$-bimodules to augmented $R$-algebras sends the initial and final object 0 to the initial and final object $R$, coproducts to coproducts, and more generally: co-Cartesian cubes to co-Cartesian cubes. Recall (see [G3]) that Goodwillie constructs $P_n F(X) = \text{hocolim}_i (T_n^i F)(X)$, and the iterated maps $T_n$ involve taking homotopy limits of the functor in question over co-Cartesian diagrams of coproducts of $X$ with the initial and final object, so this construction would be the same for $F$ on $R$-algebras and for $F(T_R(\_))$ on $R$-bimodules. Therefore, in this paper we determine the values that the finite Goodwillie Taylor approximations $P_n \tilde{K}$ take on augmented $R$-algebras which are of the form $T_R(M)$.

In the case $M = R$, the results described above are older. It has been known from work by Grayson [Gr] in 1977, at least at the level of the homotopy groups, that the K-theory of endomorphisms

$$K(R; R) \simeq \Omega \tilde{K}((1 + xR[x])^{-1}R[x]),$$

where the localization was straightforward because it is done on the level of the underlying commutative ring, and of course $R[x]$ is the same thing as $T_R(R)$. For
If $M = R$, the special version
\[ TR(R) \simeq \holim_n \Omega K(R[x]/(x)^{n+1}) \]
of our Corollary 3.2 was proved by Hesselholt [H] in the commutative case, and follows from the work of Betley and Schlichtkrull in [BS] for general $R$.

2. Preliminaries

For $R$ a unital ring and $M$ an $R$-bimodule we can look at the tensor algebra (with derived tensor products) of $M$ over $R$,
\[ T_R(M) = R \oplus M \oplus M \otimes_R M \oplus M \otimes_R M \otimes_R M \oplus \cdots . \]
Then $T_R(M)$ is an augmented $R$-algebra, and we call its augmentation ideal $I$. Note that if $M$ is an $R$-bimodule which is flat either as a right $R$-module or as a left $R$-module, then the tensoring down map $M \otimes_R^n \to M \otimes_R^n$ is a weak equivalence for every $n$. This makes $T_R(M)$ weakly equivalent to the usual tensor algebra for such $M$, which we can denote by $T_R(M)$.

We let $\mathcal{P}_R$ denote the category of projective finitely generated right $R$-modules, and $\mathcal{M}_R$ denote the category of finitely generated right $R$-modules. For an augmented $R$-algebra $A \xrightarrow{\alpha} R$ with augmentation ideal $I$ and an element $P \in \mathcal{P}_R$, we will set
\[ I_P(A) = \Hom_{\mathcal{M}_R}(P, P \otimes_R A) \cong \ker(\Hom_{\mathcal{M}_R}(P, P \otimes_R A) \xrightarrow{\alpha} \Hom_{\mathcal{M}_R}(P, P)). \]
Following the construction in section I.2.5 of [DGMcC], if we let $1_P$ denote the identity element in $\Hom(P, P)$, we can view $1_P + I_P(A)$ as a subset of $\Hom_{\mathcal{M}_R}(P \otimes_R A, P \otimes_R A)$ as follows: for $\alpha \in I_P(A)$, let
\[ (1_P + \alpha)(p \otimes a) = (p \otimes 1 + \alpha(p))a = p \otimes a + \alpha(p)a. \]
Viewed inside $\Hom_{\mathcal{M}_R}(P \otimes_R A, P \otimes_R A)$, we can compose elements of $1_P + I_P(A)$; applying this to $1_P + \alpha$ and $1_P + \beta$ will give the composition
\[ P \xrightarrow{1_P + \alpha} P \otimes A \xrightarrow{(1_P + \beta) \otimes 1_A} P \otimes A \otimes A \xrightarrow{1_P \otimes \mult_A} P \otimes A. \]
sending
\[ p \mapsto p \otimes 1 + \alpha(p) + \beta(p) + \beta(\alpha(p)) \]
where $\beta(\alpha(p))$ is interpreted using $A$-linearity as above. Note that if $\alpha, \beta$ send $P$ to $P \otimes I$, so does $\alpha + \beta + \beta(\alpha)$, so $1_P + I_P(A)$ is closed under multiplication.

If there is some reason that for any $\alpha \in I_P(A)$, $1_P + \alpha + \alpha^2 + \cdots$ is defined (such as the augmentation ideal being nilpotent or the infinite sum converging for another reason), it is in fact a group. We look at its classifying space. We can by [DGMcC] model the reduced (over $R$) $K$-theory spectrum $\tilde{K}(A)$ using Waldhausen’s S-construction
\[ \{ n \mapsto \bigvee_{P \in \Sigma^n \mathcal{P}_R} B,(1_P + I_P(A)) \}. \]
We will be looking at the augmented $R$-algebras $T_R(M)/I^{n+1}$ and
\[ T^n_R(M) = \holim_n T_R(M)/I^{n+1}. \]
They both satisfy the condition that for any $P \in \mathcal{P}_R$ and $\alpha \in I_P(A)$, $1_P + \alpha + \alpha^2 + \cdots$ is defined in $\Hom_R(P, P \otimes_R A)$.
Proposition 2.1. The functor $M \mapsto \tilde{K}(\mathcal{T}_R(M)/I^{n+1})$, as a functor from simplicial $R$-bimodules to spectra,
1) commutes with realizations
2) satisfies the colimit axiom, that is: respects filtered colimits
3) preserves connectivity of maps
4) is $-1$-analytic
so $\tilde{K}(\mathcal{T}_R(M)/I^{n+1}) = \text{holim}_k P_k \tilde{K}((\mathcal{T}_R(M)/I^{n+1})$ for all simplicial $R$ bimodules $M$.

Proof. Condition 1) follows from chapter III of [DGMcC]. Conditions 2) and 3) follow from the facts that by direct observation these properties are true for the functor $M \mapsto \mathcal{T}_R(M)/I^{n+1}$ and by [G2] they are true for the algebraic $K$-theory of simplicial rings.

By taking resolutions if necessary and using the colimit axiom, to show 4) it suffices to show that the functor of spaces

$$X \mapsto \tilde{K}((\mathcal{T}_R(M)/X)/I^{n+1})$$

is $-1$–analytic. To do this we’ll follow the process done for the case $n = 1$ in [McC] (Proposition 3.2) which is essentially a modification of work by Goodwillie in [G2].

Let $X$ be a strongly co-Cartesian $S$-cube of spaces. We may assume that the natural maps are inclusions of sub-simplicial sets. Suppose that the maps $X((s)) \to X((s))$ are $k_s$–connected for each $s \in S$. We wish to show that the stabilization of the cube of functors

$$\bigvee_{P \in \mathcal{P}_R} B.(1_P + I_P(\mathcal{T}_R(\tilde{K}[X_+]/I^{n+1})$$

$$\cong \bigvee_{P \in \mathcal{P}_R} B.(1_P + \text{Hom}_{\mathbf{M}_R}(P, P) \otimes \mathbb{Z}[X_+ \vee X_2 \vee \cdots \vee X_n])$$

is $|S| - 1 + \Sigma k_s$ Cartesian, since then the functor $\tilde{K}(\mathcal{T}_R(\tilde{K}[X_+]/I^{n+1})$ will satisfy $E_{|S| - 1}(1 - |S|)$ and hence be $-1$ analytic. If we show that the cube $B.(1_P + I_P(\mathcal{T}_R(\tilde{K}[X_+]/I^{n+1})$ is $2(|S| - 1) + (\Sigma k_s)$ co-Cartesian for all $P \in \mathcal{P}_R$, then since (homotopy) colimits commute and a $q$-reduced simplicial space of $t$-connected spaces is $(q + t)$-connected, $\bigvee_{P \in S_{t}^{|S|}} B.(1_P + I_P(\mathcal{T}_R(\tilde{K}[X_+]/I^{n+1})$ will be $(q + 2(|S| - 1) + \Sigma k_s)$-co–Cartesian. By taking $\Omega^q$ of these and the limit with respect to $q$ we will obtain a $2(|S| - 1) + \Sigma k_s$-co-Cartesian diagram of spectra which is equivalent to a $|S| - 1 + \Sigma k_s$–Cartesian diagram of spectra (see [G2], 1.19) and hence the result.

We will prove that in general, for the $S$–cube $X$

$$B.(1_P + I_P(\mathcal{T}_R(\tilde{K}[X_+]/I^{n+1}) \cong B.(1_P + \text{Hom}_R(P, P) \otimes \mathbb{Z}[X_+ \vee X_2 \vee \cdots \vee X_n])$$

is $2(|S| - 1) + \Sigma k_s$ co-Cartesian by induction on $n$. We recall that by Theorem 2.6 of [G2], to show an $S$-cube $Y$ is $2(|S| - 1) + \Sigma k_s$-co-Cartesian is suffices to show

Induction Hypothesis 2.2. For each $T \neq \emptyset$ the $T$–cube $\partial_{S-T} Y$ is $2(|T| - 1) + \Sigma_{i \in T} k_i$-Cartesian.
In proposition 3.2 of [McC], the case for $n = 1$ was done. In particular, the cube $B.(1_{P} + \text{Hom}_{R}(P, P) \otimes Z \tilde{Z}[X_{+}^{n}])$ was shown to satisfy the induction hypothesis. We have an extension of groups

$$(1_{P} + \text{Hom}_{M_{R}}(P, P) \otimes Z \tilde{Z}[X_{+}^{n}])$$

$$\xrightarrow{\tilde{\gamma}} (1_{P} + \text{Hom}_{M_{R}}(P, P) \otimes Z \tilde{Z}[X_{+}^{n} \lor X_{+}^{2} \lor \cdots \lor X_{+}^{(n-1)}])$$

Taking the bar construction we obtain a Kan fibration of cubes. By induction, the cube in the base satisfies the induction hypothesis, and so if the cube in the fiber does also, then since homotopy pullbacks commute (and these are cubes of connected spaces) the induction hypothesis will hold for the extension cube. The cube $B.(1_{P} + \text{Hom}_{M_{R}}(P, P) \otimes Z \tilde{Z}[X_{+}^{n}])$ satisfies

$$B.(1_{P} + \text{Hom}_{M_{R}}(P, P) \otimes Z \tilde{Z}[X_{+}^{n}]) \cong B.(\text{Hom}_{M_{R}}(P, P) \otimes Z \tilde{Z}[X_{+}^{n}])$$

$$\cong \text{Hom}_{M_{R}}(P, P) \otimes Z B.(\tilde{Z}[X_{+}^{n}]) \cong \text{Hom}_{M_{R}}(P, P) \otimes Z \tilde{Z}[(\Sigma X)^{n}_{+}].$$

Since $\Sigma X$ is again a strongly co-Cartesian $S$–cube with the maps $\Sigma X(0) \to \Sigma X(s)$ $k_{S} + 1$ connected for all $s \in S$, for all $T \neq \emptyset$, $\partial_{S-} \Sigma X$ is a $T$–strongly co-Cartesian cube with $k_{S} + 1$ connectivity for all $t \in T$ and so the induction hypothesis is satisfied by example 4.4 of [G2] (for the functor $X \mapsto \tilde{Z}[X_{+}^{n}])$. 

\[\square\]

3. The Main Theorem and its Corollaries

**Theorem 3.1.** For $R$ a unital ring, for every $n$ there is a natural transformation of functors of simplicial $R$-bimodules

$$\Phi_{n} : \Sigma W_{n}(R; \ ) \xrightarrow{\sim} P_{n} \tilde{K}(T_{R}^{\bar{n}}(\ ));$$

such that $\Phi_{n-1} \circ \text{res}_{n} \simeq p_{n} \circ \Phi_{n}$, which is a homotopy equivalence at any simplicial $R$-bimodule.

Note that for $M$ which are flat on one side, making the tensoring down map $M \otimes k^{n} \to M \otimes k^{n}$ into a weak equivalence for every $n$, we get that $T_{R}(M) \simeq T_{R}(M)$, so $T_{R}(M)/I^{n+1} \simeq T_{R}(M)/I^{n+1}$ and $T_{R}^{\bar{n}}(M) \simeq T_{R}^{\bar{n}}(M)$. Therefore by [W2], $\tilde{K}(T_{R}(M)) \simeq \tilde{K}(T_{R}^{\bar{n}}(M))$ and $K(T_{R}(M)) \simeq K(T_{R}^{\bar{n}}(M))$.

For the definition and properties of the $W_{n}$, see [LMcC1]. It is the inverse limit over all $i \leq n$ of the $C_{i}$ fixedpoints in the cyclic derived tensor over $R$ of $i$ copies of $M$ which was described in the introduction. The map $\text{res}_{n}$ comes from restriction of categories over which limits are taken from $\{1, 2, \ldots, n\}$ to $\{1, 2, \ldots, n - 1\}$; $p_{n}$ are the connecting maps of the Goodwillie tower of the functor.

In [LMcC1], it is shown that $W_{n}(R; \ ) = P_{n} \tilde{K}(R; \ )$, from which it follows that $\Sigma W_{n}(R; \ ) = P_{n}(\Sigma \tilde{K}(R; \ ))$. What Theorem 3.1 in fact shows is that there exists a natural transformation inducing an equivalence between Goodwillie Taylor towers of the functors $\Sigma \tilde{K}(R; \ )$ and $K(T_{R}(\ ));$. Moreover, we can draw the following

**Corollary 3.2.** For any unital ring $R$, there is a natural equivalence of functors of simplicial $R$-bimodules

$$\Sigma W(R; \ ) \to \text{holim}_{n} \tilde{K}(T_{R}(\ )/I^{n+1}).$$
Proof. (Of Corollary 3.2, given Theorem 3.1) We have, by Theorem 3.1 above, that for any $R$-bimodule $M$,

$$
(3.1) \quad \Sigma W(R; M) \overset{\text{def}}{=} \lim_k \Sigma W_k(R; M) \simeq \lim_k P_k \tilde{K}(T_R(M))
$$

which we can plug into equation (3.1) to get

$$
\Sigma W(R; M) \simeq \lim_k \lim_n P_k \tilde{K}(T_R(M)/I^{n+1})
$$

But the Taylor tower of the functor $K(\lim_n T_R(\cdot)/I^{n+1})$ can be determined by applying it to $M$ connected, where the map $\lim_n T_R(M)/I^{n+1} \to T_R(M)/I^{n_0+1}$ can be as connected as we want it to be, and $\tilde{K}$ preserves connectivity of maps, so

$$
P_k \tilde{K}(\lim_n T_R(M)/I^{n+1}) = \lim_n P_k \tilde{K}(T_R(M)/I^{n+1}),
$$

where the last equality is the convergence of the Taylor tower for $\tilde{K}(T_R(\cdot)/I^{n+1})$ from Proposition 2.1 above.

Corollary 3.3. If $R$ is a unital ring, there is a natural equivalence of functors of connected simplicial $R$-bimodules

$$
\Phi : \Sigma \tilde{K}(R; \cdot) \to \tilde{K}(T_R(\cdot)).
$$

Proof. (Of Corollary 3.3, given Theorem 3.1) The natural transformation $\Phi$ is that introduced in the beginning of the proof of Theorem 3.1 which induces the $\Phi_n$’s. The point is that for connected $M$, both the Taylor tower of $\Sigma \tilde{K}(R; \cdot)$ converges to $\Sigma \tilde{K}(R; M)$ (since that of $\tilde{K}(R; \cdot)$ converges to $\tilde{K}(R; M)$), and the Taylor tower of $\tilde{K}(T_R(\cdot))$ converges to $\tilde{K}(T_R(M))$. Moreover, for connected $M$, the map $T_R(M) \to T_R^a(M)$ is an equivalence. The fact that this map is an equivalence for connected $M$ shows that the map is order $n$ for all $n$ and hence $P_n \tilde{K}(T_R(\cdot)) \overset{\sim}{\to} P_n \tilde{K}(T_R^a(\cdot))$ for all $n$, so the convergence of the Taylor tower for $\tilde{K}(T_R(\cdot))$ for connected $M$ is in fact the convergence of the Taylor tower for $\tilde{K}(T_R^a(\cdot))$ for such $M$.

The convergence of the Taylor tower for $\tilde{K}(R; \cdot)$ follows from Theorem 9.2 in [LMcC1], which shows it for the special case of $M = \overline{N}[X]$ for $X$ connected, $N$ discrete. To go from that to the general case of $M$ connected, observe that $\tilde{K}(R; \cdot) \simeq \tilde{K}(R \times S \cdot)$ commutes with realizations by [W2]. The finite stages of the Taylor tower $W_n(R; \cdot)$ commute with realizations as finite inverse limits of the $U_0(R; \cdot)^{C_n}$ which are directly seen to commute with realizations, but for $M$ connected the map $W(R; M) \to W_n(R; M)$ is $n$-connected, that is, it can be as connected as we like by taking $n$ large enough, so $W(R; \cdot)$ commutes with realizations for connected bimodules. We want to show that the map to the Taylor tower $\tilde{K}(R; \cdot) \to W(R; \cdot)$ is an equivalence for any connected bimodule, and both sides commute with realizations for such bimodules. But any connected bimodule is homotopy equivalent to the realization of a bisimplicial set, assigning to each $n$ a simplicial set of the form covered by Theorem 9.2 in [LMcC1]. Given a general connected simplicial $R$-bimodule $M$, we can first represent it by a reduced one (that has only a single 0-simplex, the basepoint) by looking at the sub-simplicial
bimodule $M_0$ consisting of all the simplices in $M$ all of whose vertices are at the basepoint. The inclusion $M_0 \hookrightarrow M$ is an equivalence on $\pi_0$ by assumption, and on all higher homotopy groups by the definition of the homotopy groups of a simplicial abelian group. Then, replace $M_0$ by its $R \otimes R^{op}$-free simplicial resolution
\[ R \otimes R^{op}[M_0] \leftarrow R \otimes R^{op}[R \otimes R^{op}[M_0]] \leftarrow R \otimes R^{op}[R \otimes R^{op}[R \otimes R^{op}[M_0]]] \cdots \]
in which each stage is of the form $\tilde{N}[X]$ for $N = R \otimes R^{op}$ discrete and a connected simplicial $X$.

The point is that 0-simplices in $\tilde{N}$ to the following facts: by Proposition 2.1 above, the Taylor towers converge for $K(\pi_n(K)/I^{n+1}) \cong \lim_{\to} P_k \tilde{K}(\pi_n(K)/I^{n+1})$. The map $\tilde{T}_R(M) \rightarrow \tilde{T}_R(M)/I^{n+1}$ is as connected as we want it to be for $n$ large enough, and since $\tilde{K}(\ )$ preserves connectivity of maps by [W2], we get that
\[ \tilde{K}(\tilde{T}_R(M)) \cong \lim_p \tilde{K}(\tilde{T}_R(M)/I^{n+1}) \cong \lim_p \tilde{K}(\tilde{T}_R(M)/I^{n+1}) \cong \lim_p \tilde{K}(\tilde{T}_R(M)). \]

**Proof. (Of Theorem 3.1)** The augmentation ideal $I$ for $\tilde{T}_R(M) \rightarrow R$ for any $M$ is such that $1 + I$ is contained in the units of $\tilde{T}_R(M)$ and hence the fiber of the map $K(\tilde{T}_R(M)) \rightarrow K(R)$ can be section I.2.5 of [DGM03].

As before, $I_P(\tilde{T}_R(M)) = \text{Hom}_{\mathcal{A}}(P, P \otimes R)$ is considered as the ideal given by the kernel of the ring map $\text{Hom}_{\mathcal{A}}(P, P \otimes R \tilde{T}_R(M)) \rightarrow \text{Hom}_{\mathcal{A}}(P, P)$.

We define a natural transformation
\[ \phi : \Sigma \tilde{K}(R; M) \rightarrow \tilde{K}(\tilde{T}_R(M)) \]
as the stabilization of the natural transformation of the model of $\tilde{K}(R; M)$ as the stabilization of $\bigvee_{p \in \mathcal{P}_R} \text{Hom}_{\mathcal{A}}(P, P \otimes R \tilde{T}_R(M))$ and the above model of $\tilde{K}(\tilde{T}_R(M))$ which for a map $m \in \text{Hom}_{\mathcal{A}}(P, P \otimes R M)$ sends
\[ m \mapsto (1 - m)^{-1} = \sum_{i=0}^\infty m^{\otimes n^i} \]
The point is that 0-simplices in $K(R; M)$ become 1-simplices in its suspension; each such 1-simplex which comes from the 0-simplex $m$ is mapped to a 1-simplex in the classifying space corresponding to the element
\[ \sum_{i=0}^\infty m^{\otimes n^i} \in B_1(1_P + I_P(\tilde{T}_R(M))) = 1_P + I_P(\tilde{T}_R(M)). \]

Note that, for example, the notation $m^{\otimes n^2}$ means the composition
\[ (3.2) \quad P \otimes R M m^{\otimes 1^2} P \otimes R M \otimes R M \]
and is therefore also in $I_P(\tilde{T}_R(M))$.

What we want to show is that this natural transformation $\phi$ induces an equivalence of the Goodwillie Taylor towers at the basepoint $*$, and these are determined by what they do on sufficiently connected spaces. Thus, the theorem will follow once we show that $\phi$ induces an equivalence after one suspension. We would like to
establish the result using analytic continuation as in [G3]. In order to do this we first must observe that \( \tilde{K}(\mathcal{T}_R(B)) \) commutes with realizations, has the limit axiom and is 1-analytic. These are all true because the fact that \( \mathcal{T}_R^n(B) \to \mathcal{T}_R(B) \) is \( n \)-connected for all \( n \) implies \( \tilde{K}(\mathcal{T}_R^n(B)) \to \tilde{K}(\mathcal{T}_R(B)) \) is \( n \)-connected for all \( n \) and these results hold for \( \tilde{K}(\mathcal{T}_R(B)) \) for all \( n \) by Proposition [2.3] above.

Thus, we fix our \( M \), which we may assume to be connected, and are interested in the fibers of \( \Sigma \tilde{K}(R; M \oplus N) \to \Sigma \tilde{K}(R; M) \) and of \( \tilde{K}(\mathcal{T}_R^n(M \oplus N)) \to \tilde{K}(\mathcal{T}_R^n(M)) \) in a 2-connected bimodule \( \tilde{K}(R; M \oplus N) \rightarrow \Sigma \tilde{K}(R; M) \) when divided by \( \beta \) for \( R; M \) connected, since we assume that \( M \) is \( n \)-connected. Since we assume that \( M \) is connected, \( \mathcal{T}_R(M) \xrightarrow{\mathcal{T}_R(M)} \mathcal{T}_R^n(M) \) and \( \mathcal{T}_R(M \oplus N) \xrightarrow{\mathcal{T}_R(M \oplus N)} \mathcal{T}_R^n(M \oplus N) \).

For the fiber of \( \Sigma \tilde{K}(R; M \oplus N) \to \Sigma \tilde{K}(R; M) \), we can describe it using [LMcC1] which shows that for connected bimodules \( \tilde{K}(R; ) \simeq W(R; ) \) that is, for connected bimodules the Taylor tower converges to \( \tilde{K}(R; ) \) together with the splitting of Theorem 2.2 in [LMcC2] for \( W(R; ) \). We get that for \( M, N \) connected,

\[
\tilde{K}(R; M \oplus N) = \bigvee_{a=1}^{\infty} \bigvee_{\{f; \{1, \ldots, a\} \to \{M, N\}\text{ non periodic}/C_a} \tilde{K}(R; f(1) \otimes_R \cdots \otimes_R f(a)),
\]

where \( C_a \) acts on functions \( \{1, \ldots, a\} \rightarrow \{M, N\} \) by permuting \( \{1, \ldots, a\} \) cyclically before applying the function, and a function \( f \) is considered periodic if for some \( b|a \), the value of \( f(i) \) is determined by the remainder of \( i \) when divided by \( b \), that is: when if we write the values of \( f \) as a word of length \( a \) in \( M \) and \( N \), that word is a word of length \( b \) repeated \( a/b \) times. It follows from the discussion there that the maps \( M \hookrightarrow M \oplus N \xrightarrow{\mathcal{T}_R(M \oplus N)} M \) embed \( \tilde{K}(R; M) \) as the direct summand corresponding to the function from the set of one element \( 1 \rightarrow M \), so the homotopy fiber of the projection map consists of all the other summands.

The fiber of \( \tilde{K}(\mathcal{T}_R(M \oplus N)) \rightarrow \tilde{K}(\mathcal{T}_R(M)) \) is exactly the algebraic K-theory of \( \mathcal{T}_R(M \oplus N) \) reduced over \( \mathcal{T}_R(M) \). We can compare this reduced algebraic K-theory to that of another ring: Note that, by sending any terms with more than one tensored entry in \( N \) to the basepoint, we have a 2-connected multiplicative map

\[
\mathcal{T}_R(M \oplus N) \xrightarrow{\beta} \mathcal{T}_R(M) \otimes (\mathcal{T}_R(M) \otimes_R N \otimes_R \mathcal{T}_R(M)).
\]

We can put all this together in a commutative diagram

\[
(3.3) \quad \Sigma \tilde{K}(R; M) \xrightarrow{\phi} \Sigma \tilde{K}(R; M \oplus N) \xrightarrow{\phi} \Sigma \tilde{K}(R; N) \bigvee \Sigma \tilde{K}(R; \otimes_R f(i)) \xrightarrow{\alpha} \tilde{K}(\mathcal{T}_R(M)) \xrightarrow{\Psi} \tilde{K}(\mathcal{T}_R(M \oplus N)) \xrightarrow{\beta} \tilde{K}(\mathcal{T}_R(M \oplus N)) \xrightarrow{\Psi} \tilde{K}(\mathcal{T}_R(M) \otimes N) \xrightarrow{\beta} \tilde{K}(\mathcal{T}_R(M) \otimes N) \xrightarrow{\Psi} \tilde{K}(\mathcal{T}_R(M) \otimes N) \xrightarrow{\beta} \tilde{K}(\mathcal{T}_R(M) \otimes N).
\]
where
\[
\bigvee_{a=2}^{\infty} \bigvee_{\{f: \{1, \ldots, a\} \to \{M, N\}\text{ non periodic}\}/C_a} \Sigma \tilde{K}(R; f(1) \otimes_R \cdots \otimes_R f(a))
\]
and
\["T_R(M) \ltimes N" = T_R(M) \ltimes (T_R(M) \otimes_R N \otimes_R T_R(M)).\]

The left column maps to the center column by maps induced by the obvious inclusions. Since the inclusions are all inclusions of retracts, the spectra in the center column all split as the product of the spectrum on their left and the spectrum on their right.

Our goal is to show that when \(N\) is \(n\)-connected, \(\alpha\) is \(2n\)-connected in equation (3.3). This would mean that \(\phi\) induces an equivalence of the Goodwillie differentials at \(M\). Since \(\Psi\) is \(2n\)-connected, \(\Psi^*\) and therefore also \(\beta\) are \(2n\)-connected as well. So our strategy will be to show that \(\beta \circ \alpha\) is \(2n\)-connected, and deduce from that that \(\alpha\) is.

It is plausible that \(\beta \circ \alpha\) is \(2n\)-connected, since we will now see that its target and source have the same homotopy type in these dimensions. In the next sections, we will see that \(\beta \circ \alpha\) actually induces a \(2n\)-equivalence.

We can map
\begin{align*}
\Sigma \tilde{K}(R; N) & \bigvee_{a=2}^{\infty} \bigvee_{\{f: \{1, \ldots, a\} \to \{M, N\}\text{ non periodic}\}/C_a} \Sigma \tilde{K}(R; f(1) \otimes_R \cdots \otimes_R f(a)) \\
2n & \bigvee_{a=0}^{\infty} \Sigma \tilde{K}(R; M \otimes_R^a \otimes_R N) 2n \bigvee_{a=0}^{\infty} \Sigma \text{THH}(R; M \otimes_R^a \otimes_R N) \\
& \simeq \text{THH}(R; T_R(M) \otimes_R^\otimes \Sigma N)
\end{align*}
where the first map collapses all terms corresponding to \(f\)'s which hit \(N\) more than once, and since reduced \(K\)-theory sends \(2n\)-connected bimodules to \(2n\)-connected spectra, it is \(2n\)-connected; the second map is \(2n\)-connected by [DMcC1], and the last map is an equivalence by the linearity of \(\text{THH}\) in the bimodule variable and since \(M\) is connected.

By [DMcC1],
\[K_{T_R(M)}(T_R(M) \ltimes T_R(M) \otimes_R N) \otimes_R T_R(M) \simeq K(T_R(M); \Sigma T_R(M) \otimes_R N \otimes_R T_R(M)) \]
\[2n \simeq \text{THH}(T_R(M); \Sigma T_R(M) \otimes_R N \otimes_R T_R(M))\]
and by Lemma 4.2 below, there is a homotopy equivalence
\[\text{THH}(R; T_R(M) \otimes_R^\otimes \Sigma N) \xrightarrow{\simeq} \text{THH}(T_R(M); T_R(M) \otimes_R^\otimes \Sigma N \otimes_R^\otimes T_R(M)),\]
the same spectrum we ended up with in equation (3.4).
4. Checking that the Equivalence is Induced by the Correct Map

This section is dedicated to finishing the proof of Theorem 3.1 by tracing the maps in (3.3) to establish that \( \beta \circ \alpha \) in fact induces a \( 2n \)-equivalence for \( N \) \( n \)-connected. We will first need some lemmas, which will all be proven in the last section of the paper.

**Lemma 4.1.** Model \( \tilde{K}(R; M \oplus N) \) by Waldhausen’s S-construction as the stabilization of
\[
\bigvee_{P \in S^{(n)} \mathcal{P}_R} \text{Hom}_R(P, P \otimes_R (M \oplus N)) \cong \bigvee_{P \in S^{(n)} \mathcal{P}_R} \text{Hom}_R(P, P \otimes_R M) \oplus \text{Hom}_R(P, P \otimes_R N);
\]
model, similarly,
\[
\tilde{K}_{T_R(M)}(T_R(M) \times (T_R(M) \otimes_R N \otimes_R T_R(M))) \simeq \tilde{K}(T_R(M); B(\mathcal{T}_R(M) \otimes_R N \otimes_R T_R(M)))
\]
(this is the homotopy equivalence of [DMMcC1] as the stabilization of
\[
\bigvee_{Q \in S^{(n)} \mathcal{P}_{T_R(M)}} \text{Hom}_{T_R(M)}(Q, Q \otimes_{T_R(M)} B(\mathcal{T}_R(M) \otimes_R N \otimes_R T_R(M))).
\]

Then if we start at the middle of the top row of diagram (3.3), follow the maps \( \phi \) and \( \Psi_* \) down and then the map which goes right, the resulting map
\[
\tilde{K}(R; M \oplus N) \to \tilde{K}_{T_R(M)}(T_R(M) \times (T_R(M) \otimes_R N \otimes_R T_R(M)))
\]
\[
\simeq \tilde{K}(T_R(M); B(\mathcal{T}_R(M) \otimes_R N \otimes_R T_R(M)))
\]
is induced by sending the suspension \( \Sigma(m, n) \) of each \( (m, n) \in \text{Hom}_R(P, P \otimes M) \oplus \text{Hom}_R(P, P \otimes N) \) to
\[
(1_{P \otimes_{T_R(M)}} - m)^{-1} \otimes n
\]
\[
\in \text{Hom}_{T_R(M)}(P \otimes R T_R(M), P \otimes R T_R(M) \otimes_{T_R(M)} T_R(M) \otimes_R N \otimes_R T_R(M))
\]
\[
= \text{Hom}_{T_R(M)}(P \otimes R T_R(M), P \otimes R T_R(M) \otimes_{T_R(M)} B_1(T_R(M) \otimes_R N \otimes_R T_R(M)))
\]
in the summand corresponding to \( Q = P \otimes R T_R(M) \).

**Lemma 4.2.** Let \( R \) be a ring spectrum, and \( S \) an \( R \)-algebra. Let \( X \) be an \( S \)-\( R \) bimodule. Then there is a homotopy equivalence
\[\text{THH}(R; X) \xrightarrow{\sim} \text{THH}(S; X \otimes_R^\wedge S).\]

**Lemma 4.3.** Let \( R \) be a simplicial ring, \( S \) a simplicial \( R \)-algebra, and \( X \) a simplicial \( S \)-\( R \) bimodule. Then if we construct \( \text{THH}(R; M) \) for an \( R \)-bimodule \( M \) via the Waldhausen \( S \)-construction
\[
\{n \mapsto \oplus_{P \in S^{(n)} \mathcal{P}_R} \text{Hom}_{S^{(n)} \mathcal{M}_R}(P, P \otimes_R M)\},
\]
the isomorphism
\[\text{THH}(R; X) \simeq \text{THH}(R; S \otimes_R^\wedge X)\]
of Lemma 4.2 for the associated Eilenberg Mac Lane spectra is induced by the map
\[
\oplus_{P \in S^{(n)} \mathcal{P}_R} \text{Hom}_{S^{(n)} \mathcal{M}_R}(P, P \otimes_R X) \to \oplus_{Q \in S^{(n)} \mathcal{P}_S} \text{Hom}_{S^{(n)} \mathcal{M}_S}(Q, Q \otimes_S (X \otimes_R^\wedge S))
\]
sending
\[
\alpha: P \to P \otimes_R X
\]
to
\[ \alpha \otimes_R 1_S : P \otimes_R S = P \otimes_R S \to P \otimes_R S \otimes_S X \otimes_R S \simeq P \otimes_R X \otimes_R S. \]

Using these lemmas, we will be able to complete our proof of Theorem 3.1. The [DMcC1] map
\[ (4.1) \tilde{K}(T_R(M); B.(T_R(M) \otimes_R N \otimes_R T_R(M))) \]
is obtained simply by passing from \( \bigvee \) to \( \bigoplus \),
\[ \bigvee_{Q \in R_{T_R(M)}} \text{Hom}_{T_R(M)}(Q, Q \otimes_{T_R(M)} B.(T_R(M) \otimes_R N \otimes_R T_R(M))) \]
\[ \to \bigoplus_{Q \in R_{T_R(M)}} \text{Hom}_{T_R(M)}(Q, Q \otimes_{T_R(M)} B.(T_R(M) \otimes_R N \otimes_R T_R(M))). \]

So by Lemma [4.1] above, the composition of \( \Psi_* \circ \phi \) with the [DMcC1] linearization map \( \{1\} \) sends the loop represented by the 1-simplex \( \Sigma(m, n) \) in the \( P \) summand to something homotopic to the loop represented by the 1-simplex \( (1_{P \otimes_R T_R(M)} - m)^{-1} \otimes n \) in the \( P \otimes_R T_R(M) \) summand.

Alternatively, if we look at the map onto the cofiber on the top row of equation (3.3) and then collapse to a point the terms with more than one \( N \),
\[ (4.2) \tilde{K}(R; M \oplus N) \]
\[ \to \tilde{K}(R : N) \bigvee_{a=2}^{\infty} \bigvee_{f : \{1, \ldots, a\} \to \{M, N\} \text{ non periodic}/C_a} \tilde{K}(R; f(1) \otimes_R \cdots \otimes_R f(a)) \]
\[ \simeq \bigvee_{a=0}^{\infty} \tilde{K}(R; M^\otimes a \otimes_R N) \simeq \prod_{a=0}^{\infty} \tilde{K}(R; M^\otimes a \otimes_R N) \]
it is induced by the stabilization of the product of the maps
\[ \bigvee_{P \in P_R} (\text{Hom}_R(P, P \otimes M) \oplus \text{Hom}_R(P, P \otimes N)) \to \bigvee_{P \in P_R} \text{Hom}_R(P, P \otimes M \otimes a \otimes_R N) \]
sending
\[ (m, n) \mapsto m^\otimes a \otimes n. \]
To see this, we use the fact that \( M \) is connected and \( N \) is \( n \)-connected for \( n \) which we may assume to be at least 1, and therefore \( M \oplus N \) is connected as well. Then
\[ (4.3) \tilde{K}(R; M \oplus N) \iso \tilde{K}(R; M \oplus N) \]
\[ \simeq \prod_{a=1}^{\infty} \bigvee_{f : \{1, \ldots, a\} \to \{M, N\} \text{ non periodic}/C_a} W(R; f(1) \otimes_R \cdots \otimes_R f(a)) \]
\[ \iso \bigvee_{a=0}^{\infty} W(R; M^\otimes a \otimes_R N) \simeq \tilde{K}(R; M) \times \prod_{a=0}^{\infty} \tilde{K}(R; M^\otimes a \otimes_R N) \]
Here the first and last equivalences are by Theorem 9.2 in [LMcC1], the second one is the splitting of Theorem 2.2 in [LMcC2], and the third map is 2n-connected because if $f$ hits $N$ more than once, $f(1) \otimes^\wedge_R \cdots \otimes^\wedge_R f(a)$ and therefore also $W$ of $R$ with coefficients in it are 2n-connected.

We are, of course, quotienting this whole picture out by $\tilde{K}(R; M)$. By following the decomposition of Theorem 2.2 in [LMcC2] on the 0-dimensional part (as we did before), we see that

$$(m, n) \in \text{Hom}_R(P, P \otimes M) \oplus \text{Hom}_R(P, P \otimes N)$$

in $\tilde{K}(R; M \oplus N)$ in the beginning of equation [4.3] lands in the same place in $W(R; M) \times \prod_{a=0}^\infty W(R; M^\otimes^\wedge_R a \otimes^\wedge_R N)$ as $\{m\} \times \prod_{a=0}^\infty \{m^\otimes a \otimes n\}$ in $\tilde{K}(R; M) \times \prod_{a=0}^\infty \tilde{K}(R; M^\otimes^\wedge_R a \otimes^\wedge_R N)$ on the right. Since the spectra we are looking at increase in connectivity, we know that their sum $\bigvee$ is homotopy equivalent to their product.

In [3.3], we are using the suspension of the map of [4.2],

$$\Sigma \tilde{K}(R; M \oplus N) \rightarrow \Sigma \bigvee_{a=0}^\infty \tilde{K}(R; M^\otimes^\wedge_R a \otimes^\wedge_R N)$$

and want to compose it with

$$\Sigma \bigvee_{a=0}^\infty \tilde{K}(R; M^\otimes^\wedge_R a \otimes^\wedge_R N) \xrightarrow{2n\rightarrow1} \Sigma \bigvee_{a=0}^\infty \text{THH}(R; M^\otimes^\wedge_R a \otimes^\wedge_R N)$$

$$\simeq \text{THH}(R; \Sigma \bigoplus_{a=0}^\infty M^\otimes^\wedge_R a \otimes^\wedge_R N) \simeq \text{THH}(R; \Sigma T_R(M) \otimes^\wedge_R N),$$

where the first map is that of [DMcC1], and the second uses the linearity of THH in the bimodule coordinate.

So the suspension of $(m, n) \in \text{Hom}_R(P, P \otimes M) \oplus \text{Hom}_R(P, P \otimes N)$ lands in the 1-simplex corresponding to

$$\sum_{a=0}^\infty m^\otimes a \otimes n = (1_R - m)^{-1} \otimes n \in \text{Hom}_R(P, P \otimes_R T_R(M) \otimes^\wedge_R N).$$

When we went the $\Psi_* \circ \phi$ route, instead of getting

$$(1_R - m)^{-1} \otimes n \in \text{Hom}_{T_R(M)}(P \otimes_R T_R(M) \otimes^\wedge_R N) \subset \text{THH}(R; T_R(M) \otimes^\wedge_R N)$$

we got

$$(1_R \otimes^\wedge_R T_R(M) - m)^{-1} \otimes n$$

$$\in \text{Hom}_{T_R(M)}(P \otimes_R T_R(M), P \otimes_R T_R(M) \otimes^\wedge_R N \otimes^\wedge_R T_R(M))$$

$$\subset \text{THH}(T_R(M); T_R(M) \otimes^\wedge_R N \otimes^\wedge_R T_R(M)).$$

But by Lemmas 4.2 and 4.3 above, that is exactly what we need to assure ourselves that up to homotopy, the map $\beta \circ \alpha$ is the 2n-equivalence we were after. \qed

5. Proofs of the Technical Lemmas

Lemma 4.1
Proof: The discussion will be done over $\mathcal{P}_R$, i.e. in the first stage of the Waldhausen S-construction, but can be carried over to $S^{(n)}\mathcal{P}_R$ for any $n$.

The map

$$\Sigma \tilde{K}(R; M \oplus N) \xrightarrow{\mu} \tilde{K}(\mathcal{T}_R(M \oplus N))$$

was induced by stabilizing the map

$$\Sigma \bigvee_{P \in \mathcal{P}_R} \text{Hom}_R(P, P \otimes_R (M \oplus N)) \xrightarrow{\cong} \bigvee_{P \in \mathcal{P}_R} B.(1_P + I_P(\mathcal{T}_R(M \oplus N)))$$

sending $\Sigma(m, n)$ to the 1-simplex

$$1_P + (m + n) + (m + n)^{\otimes 2} + (m + n)^{\otimes 3} + \cdots \in B_1(1_P + I_P(\mathcal{T}_R(M \oplus N))).$$

Now $\Psi_* : \tilde{K}(\mathcal{T}_R(M \oplus N)) \to \tilde{K}(\mathcal{T}_R(M)) \times (\mathcal{T}_R(M) \otimes_R N \otimes_R \mathcal{T}_R(M)))$ is induced by

$$\Psi_* : \bigvee_{P \in \mathcal{P}_R} B.(1_P + I_P(\mathcal{T}_R(M \oplus N)))$$

$$\to \bigvee_{P \in \mathcal{P}_R} B.(1_P + I_P(\mathcal{T}_R(M)) \times (\mathcal{T}_R(M) \otimes_R N \otimes_R \mathcal{T}_R(M)))$$

so the original 1-simplex $\Sigma(m, n)$ will be further sent to the 1-simplex

$$1_P + \sum_{i=1}^{\infty} m^{\otimes i} + \sum_{j,k=0}^{\infty} m^{\otimes j} \otimes n \otimes m^{\otimes k}$$

$$= (1_P - m)^{-1} + (1_P - m)^{-1} \otimes n \otimes (1_P - m)^{-1}.$$
when we pass from \( \tilde{K}_R \) to \( \tilde{K}_{R(m)} \), we are identifying \( \tilde{K}_R(\mathcal{T}_R(M)) \) to a point, and so at each level of the stabilization, the image of our original 1-simplex \( \Sigma(m, n) \) will be homotopic (rel endpoints) to the image of the 1-simplex

\[
1_p + (1_p - m)^{-1} \otimes n \in B_1(1_p + I_p(\mathcal{T}_R(M) \times (\mathcal{T}_R(M) \otimes_R N \otimes_R \mathcal{T}_R(M)))).
\]

Now when \( \tilde{K}_{R(m)}(\mathcal{T}_R(M) \times (\mathcal{T}_R(M) \otimes_R N \otimes_R \mathcal{T}_R(M))) \) is represented as the stabilization of

\[
\bigvee_{Q \in \mathcal{P}_{\mathcal{T}_R(M)}} B.(1_Q + I_Q(\mathcal{T}_R(M) \times (\mathcal{T}_R(M) \otimes_R N \otimes_R \mathcal{T}_R(M)))
\]

(note that the augmentation ideal here refers now to augmentation over \( \mathcal{T}_R(M) \)), then \( 1_p + (1_p - m)^{-1} \otimes n \) should be viewed there not as an \( R \)-linear map

\[
P \rightarrow P \otimes_R (\mathcal{T}_R(M) \times (\mathcal{T}_R(M) \otimes_R N \otimes_R \mathcal{T}_R(M)))
\]

but as its \( \mathcal{T}_R(M) \)-linear extension to

\[
P \otimes_R \mathcal{T}_R(M) \rightarrow (P \otimes_R \mathcal{T}_R(M)) \otimes_{\mathcal{T}_R(M)} (\mathcal{T}_R(M) \times (\mathcal{T}_R(M) \otimes_R N \otimes_R \mathcal{T}_R(M))) \equiv P \otimes_R (\mathcal{T}_R(M) \times (\mathcal{T}_R(M) \otimes_R N \otimes_R \mathcal{T}_R(M))).
\]

(Extending maps \( \mathcal{T}_R(M) \)-linearly gives an isomorphism

\[
\text{Hom}_R(P, P \otimes_R S) \leftrightarrow \text{Hom}_{\mathcal{T}_R(M)}(P \otimes_R \mathcal{T}_R(M), (P \otimes_R \mathcal{T}_R(M)) \otimes_{\mathcal{T}_R(M)} S).
\]

So now our original simplex \( \Sigma(m, n) \) maps to the 1-simplex

\[
1_{p \otimes_R \mathcal{T}_R(M)} + (1_{p \otimes_R \mathcal{T}_R(M)} - m)^{-1} \otimes n \in B_1(1_{p \otimes_R \mathcal{T}_R(M)} + I_{p \otimes_R \mathcal{T}_R(M)}(\mathcal{T}_R(M) \times (\mathcal{T}_R(M) \otimes_R N \otimes_R \mathcal{T}_R(M))))
\]

in the \( \bigvee_{Q \in \mathcal{P}_{\mathcal{T}_R(M)}} B.(1_Q + I_Q(\mathcal{T}_R(M) \times (\mathcal{T}_R(M) \otimes_R N \otimes_R \mathcal{T}_R(M)))) \) model of \( \tilde{K}_{R(m)}(\mathcal{T}_R(M) \times (\mathcal{T}_R(M) \otimes_R N \otimes_R \mathcal{T}_R(M))) \) which admits a homotopy equivalence

\[
\tilde{K}(\mathcal{T}_R(M); B.(\mathcal{T}_R(M) \otimes_R N \otimes_R \mathcal{T}_R(M))) \cong \tilde{K}_{R(m)}(\mathcal{T}_R(M) \times (\mathcal{T}_R(M) \otimes_R N \otimes_R \mathcal{T}_R(M)))
\]

described in section 4 of [DMcC]. Following the description there, this homotopy equivalence is the stabilization of a given map

\[
\bigvee_{Q \in \mathcal{P}_{\mathcal{T}_R(M)}} \text{Hom}_{\mathcal{T}_R(M)}(Q, Q \otimes_{\mathcal{T}_R(M)} B.(\mathcal{T}_R(M) \otimes_R N \otimes_R \mathcal{T}_R(M)))
\]

\[\rightarrow \bigvee_{Q \in \mathcal{P}_{\mathcal{T}_R(M)}} B.(1_Q + I_Q(\mathcal{T}_R(M) \times (\mathcal{T}_R(M) \otimes_R N \otimes_R \mathcal{T}_R(M))))\]

which sends the 1-simplex corresponding to

\[
\alpha : Q \rightarrow Q \otimes_{\mathcal{T}_R(M)} (\mathcal{T}_R(M) \otimes_R N \otimes_R \mathcal{T}_R(M))
\]

\[
= Q \otimes_{\mathcal{T}_R(M)} B_1(\mathcal{T}_R(M) \otimes_R N \otimes_R \mathcal{T}_R(M))
\]

to

\[
1_Q + \alpha \in 1_Q + I_Q(\mathcal{T}_R(M) \times (\mathcal{T}_R(M) \otimes_R N \otimes_R \mathcal{T}_R(M))
\]

\[
= B_1(1_Q + I_Q(\mathcal{T}_R(M) \times (\mathcal{T}_R(M) \otimes_R N \otimes_R \mathcal{T}_R(M)))).
\]
Therefore the loop corresponding to $1_{P \otimes_R T_R(M)} + (1_{P \otimes_R T_R(M)} - m)^{-1} \otimes n$ in $\tilde{K}_{T_R(M)}(T_R(M) \otimes_R N) \otimes_R T_R(M)$ comes from

$$(1_{P \otimes_R T_R(M)} - m)^{-1} \otimes n : P \otimes_R T_R(M) \to T_R(M) \otimes_R N \otimes_R T_R(M).$$

\[\square\]

\textbf{Lemma 4.2}

\textbf{Proof.} We look at the bisimplicial spectrum

$$(p, q) \mapsto S^{\Lambda p} \wedge X \wedge R^{\Lambda q} \wedge S$$

with the usual Hochschild-type face and degeneracy maps in both simplicial dimensions. Realizing first in the $p$-direction, we get that the realization of this bisimplicial set is

$$\text{THH}(R; S \otimes^L_X X) \simeq \text{THH}(R; X);$$

realizing first in the $q$-direction, we get that the realization is

$$\text{THH}(S; X \otimes^L_R S).$$

\[\square\]

\textbf{Lemma 4.3}

\textbf{Proof.} We will use the methods of [DMcC2]: we can model the product $\bigwedge_{p, q} S^{\Lambda p} \wedge X \wedge R^{\Lambda q} \wedge S$ of the Eilenberg Mac Lane spectra associated to the simplicial rings and modules by

$$(5.1) \quad \text{hocolim}_{\Delta} \text{Map}(S^{\Delta_n} \wedge \bigwedge_{\Delta} \text{Hom}_S(Q_1, Q_0)[S^{X_0^1}] \wedge \cdots \wedge \text{Hom}_S(Q_p, Q_{p-1})[S^{X_{p-1}^1}]$$

$$\wedge \text{Hom}_R(P_0, Q_0 \otimes_R X)[S^{X_0^1}] \wedge \text{Hom}_R(P_1, P_0)[S^{X_1^2}] \wedge \cdots$$

$$\wedge \text{Hom}_R(P_q, P_{q-1})[S^{X_{q-1}^2}] \wedge \text{Hom}_S(Q_0, P_q \otimes_R S)[S^{X_q^2}]$$

where $X = (X_0^1, \ldots, X_p^1, X_0^2, \ldots, X_q^2)$ is a collection of finite sets and where $\Delta = (Q_0, \ldots, Q_p, P_0, \ldots, P_q)$, $Q_i \in \mathcal{P}_S$, $P_i \in \mathcal{P}_R$.

Boundary maps in this model come from the composition of maps, smashed with identity maps of a bimodule as needed, and the smashing together of spheres.

For the elements we need to represent, we can take $p = q = 0$ and $X_i^j = \emptyset \forall i, j$, and look at elements in

$$\text{Hom}_R(P, Q \otimes_R X) \wedge \text{Hom}_S(Q, P \otimes_R S)$$

for $P \in \mathcal{P}_R$ and $Q \in \mathcal{P}_S$.

Given a $P \in \mathcal{P}_R$ and an $R$-linear map $\alpha : P \to P \otimes_R X$ (where the $S - R$-bimodule $X$ is viewed as a left $R$-module through the unit map $R \to S$), we look at $Q = P \otimes_R S \in \mathcal{P}_S$. Since

$$Q \otimes_S X = (P \otimes_R S) \otimes_S X \cong P \otimes_R X,$$

$\alpha$ can be viewed as an element of $\text{Hom}_R(P, Q \otimes_S X)$. Consider

$$(\alpha, 1_Q) \in \text{Hom}_R(P, Q \otimes_S X) \wedge \text{Hom}_S(Q, P \otimes_R S).$$
If we map $S^\wedge p \wedge R^\wedge q \wedge S \to \text{THH}(R; X \otimes_S^S S)$, then $(\alpha, 1_Q)$ will be identified with the composition

$$P \xrightarrow{\alpha} Q \otimes_S X \xrightarrow{\alpha \otimes_S^S 1_X} (P \otimes_R S) \otimes_S X \cong P \otimes_R X$$

that is, with $\alpha \in \text{Hom}_R(P, P \otimes_R X)$. But if we map $S^\wedge p \wedge X \wedge R^\wedge q \wedge S \to \text{THH}(S; X \otimes_R^R S)$, $(\alpha, 1_Q)$ will be identified with the composition

$$Q \xrightarrow{1_Q} P \otimes_R S \xrightarrow{\alpha \otimes_R^R 1_S} (Q \otimes_S X) \otimes_R S$$

which is the map we called

$$\alpha \otimes_R^R 1_S \in \text{Hom}_S(P \otimes_R^R S, P \otimes_R^R X \otimes_R^R S).$$

This argument holds for any stage $n$ in the Waldhausen $S$-construction. □
